(54) Title: METAL RESISTANT MR IMAGING REFERENCE SCAN

Fig. 2

(57) **Abstract:** The invention relates to a method of parallel MR imaging, wherein a reference scan is performed by means of a stimulated echo sequence including i) at least two preparation RF pulses (α) radiated toward a portion of a body (10) during a preparation period (21), and ii) one or more reading RF pulses (β) radiated toward the portion of the body (10) during an acquisition period (22) temporally subsequent to the preparation period (21). One or more FID signals (I_1) and one or more stimulated echo signals (I_2) are acquired during the acquisition period (22). The spatial receive and/or -if applicable -transmit4 sensitivity profiles of at least two RF coils (11, 12, 13) are derived from the acquired FID signals (I_1) and/or from the acquired stimulated echo signals (I_2). The parameters of the stimulated echo sequence are selected such that it is robust against susceptibility-induced artefacts. Moreover, 10 the invention relates to a MR device (1) and to a computer program for a MR device (1).

METAL RESISTANT MR IMAGING REFERENCE SCAN

FIELD OF THE INVENTION

The invention relates to the field of magnetic resonance (MR) imaging. It concerns methods of MR imaging of at least a portion of a body. The invention also relates to a MR device and to a computer program to be run on a MR device.

5

BACKGROUND OF THE INVENTION

Image-forming MR methods which utilize the interaction between magnetic fields and nuclear spins in order to form two-dimensional or three-dimensional images are widely used nowadays, notably in the field of medical diagnostics, because for the imaging of 10 soft tissue they are superior to other imaging methods in many respects, do not require ionizing radiation and are usually not invasive.

According to the MR method in general, the body of the patient to be examined is arranged in a strong, uniform magnetic field (B_0 field) whose direction at the same time defines an axis (normally the z-axis) of the co-ordinate system in which the 15 measurement is based. The magnetic field splits different energy levels for the individual nuclear spins in dependence on the magnetic field strength and the specific spin properties. The spin system can be excited (spin resonance) by application of an electromagnetic alternating field (RF field, also referred to as B_1 field) of defined frequency (so-called Larmor frequency, or MR frequency). From a macroscopic point of view the distribution of 20 the individual nuclear spins produces an overall magnetization which can be deflected out of the state of equilibrium by application of an above mentioned electromagnetic pulse of appropriate radio frequency (RF pulse) while the corresponding B_1 magnetic field extends perpendicular to the z-axis, so that the magnetization performs a precessional motion about the z-axis. The precessional motion describes a surface of a cone whose angle of aperture is 25 referred to as flip angle. The magnitude of the flip angle is dependent on the strength and the duration of the applied electromagnetic RF pulse. In the case of a so-called 90° pulse, the spins are deflected from the z axis to the transverse plane (flip angle 90°).

After termination of the RF pulse, the magnetization relaxes back to the original state of equilibrium, in which the magnetization in the z direction is built up again

with a first time constant T_1 (spin lattice or longitudinal relaxation time), and the magnetization in the direction perpendicular to the z direction relaxes with a second time constant T_2 (spin-spin or transverse relaxation time). The variation of the magnetization can be detected by means of one or more receiving RF coils which are arranged and oriented

5 within an examination volume of the MR device in such a manner that the variation of the magnetization is measured in the direction perpendicular to the z-axis. The decay of the transverse magnetization is accompanied, after application of, for example, a 90° pulse, by a transition of the nuclear spins (induced by local magnetic field inhomogeneities) from an ordered state with the same phase to a state in which all phase angles are uniformly

10 distributed (dephasing). The dephasing can be compensated by means of a refocusing pulse (for example a 180° pulse). This produces an echo signal (spin echo) in the receiving coils.

In order to realize spatial resolution in the body, linear magnetic field gradients extending along the three main axes are superposed on the uniform magnetic field, leading to a linear spatial dependency of the spin resonance frequency. The signal picked up

15 in the receiving coils then contains components of different frequencies which can be associated with different locations in the body. The MR signal data obtained via the RF coils corresponds to the spatial frequency domain and is called k-space data. The k-space data are usually acquired along multiple lines with different phase encoding values to achieve sufficient coverage. Each line is digitized during read-out by collecting a number of samples.

20 A set of k-space data is converted to a MR image by means of Fourier transformation.

With aging population and an increasing number of patients carrying metal implants, the need for MR imaging of soft tissue in the presence of metal increases. Metal resistant MR imaging is required to enable imaging this soft tissue for diagnosis of complications and follow-up after surgery. MR imaging near metal is typically compromised

25 by susceptibility issues degrading the magnetic fields used for image formation locally. In diagnostic MR imaging scans, the susceptibility of the metal parts causes MR signal pile-up, signal voids and other geometric distortions. Multispectral imaging techniques like SEMAC (Lu et al, ISMRM 2008, p. 838) and MAVRIC (Koch et al, ISMRM 2008, p. 1250) have been proposed to counter susceptibility issues in diagnostic MR imaging scans at the cost of

30 increased scan duration, which scales with the required frequency coverage.

Known parallel acquisition techniques can be used for accelerating the multispectral MR signal acquisition. A method in this category is SENSE (Sensitivity Encoding). SENSE and other parallel acquisition techniques use undersampled k-space data acquisition obtained from multiple RF receiving coils in parallel. In these methods, the

(complex) signal data from the multiple RF receive coils are combined with complex weightings in such a way as to suppress undersampling artifacts (aliasing) in the finally reconstructed MR images. This type of complex RF coil array signal combination is sometimes referred to as spatial filtering and includes combining in the k-space domain or in 5 the image domain (in SENSE), as well as methods which are hybrids. In SENSE imaging, coil sensitivity profiles are typically estimated from low-resolution reference data. This coil sensitivity information is then used to “unwrap” aliased pixels in image space using a direct inversion algorithm.

The present standard for the SENSE reference scan is a FFE (Fast Field Echo 10 = gradient echo with small flip-angle excitation) acquisition protocol, which makes it very sensitive to susceptibility effects. When the susceptibility of metal parts compromises the quality of the SENSE reference scan, it may cause SENSE unfolding problems and signal voids resulting in an insufficient quality of the finally reconstructed MR images. Using a TSE (Turbo Spin Echo = spin echo with multiple 180° refocusing RF pulses) SENSE reference 15 scan has been shown to be more robust against susceptibility effects, thereby reducing problems like incorrect SENSE unfolding and signal voids. However, a TSE SENSE reference scan may take a full minute or more, which is substantially longer than the standard FFE SENSE reference scan, which takes typically less than 10 seconds.

From the foregoing it is readily appreciated that there is a need for an 20 improved parallel MR imaging technique that is sufficiently fast to enable multispectral imaging and that is robust against susceptibility effects.

In accordance with the invention, a method of MR imaging of at least a portion of a body placed in the examination volume of a MR device is disclosed. The method comprises the steps of:

- 25 - subjecting the portion of the body to a first imaging sequence of RF pulses and switched magnetic field gradients, which imaging sequence is a stimulated echo sequence including:
 - i) at least two preparation RF pulses radiated toward the portion of the body during a preparation period, and
 - 30 ii) one or more reading RF pulses radiated toward the portion of the body during an acquisition period temporally subsequent to the preparation period;
- acquiring one or more FID signals and one or more stimulated echo signals during the acquisition period by means of parallel signal acquisition via at least two RF coils having different spatial receive sensitivity profiles within the examination volume; and

- deriving the spatial receive sensitivity profiles of the at least two RF coils from the acquired FID signals and/or from the acquired stimulated echo signals.

In general, a stimulated echo sequence comprises three (for example 60° or 90°) RF pulses, wherein the first two RF pulses are preparation pulses. The first preparation 5 RF pulse excites magnetic resonance and transforms the longitudinal nuclear magnetization into transverse nuclear magnetization. The second preparation RF pulse stores a fraction of the de-phased transverse nuclear magnetization along the longitudinal axis. In case of 90° RF pulses this fraction is almost half of the de-phased transverse magnetization. The third RF pulse is applied during the acquisition period which is temporally subsequent to the 10 preparation period. The third RF pulse (“reading RF pulse”) transforms the stored longitudinal nuclear magnetization into transverse nuclear magnetization again, thereby generating a so-called stimulated echo. Furthermore, it generates a FID signal from the remaining longitudinal magnetisation. Other RF refocused echoes could potentially be generated by this three RF pulse sequence, but those are not of interest here and may be 15 suppressed by appropriate gradient switching regimes running in parallel to the RF irradiation.

The stimulated echo MR signal together with the FID signal, which is also generated by the third RF pulse, is acquired according to the invention. MR imaging on the basis of the stimulated echoes can be accelerated by replacing the third RF pulse by a train of low-flip angle reading RF pulses, wherein each reading RF pulse refocuses only a small 20 portion of the longitudinal nuclear magnetization stored after the preparation period.

The at least two preparation RF pulses used to store magnetization along the z-axis do not have to be of the same kind or flip angle. However, with respect to the mathematical treatment necessary to evaluate the measuring data, the choice of identical RF pulses and flip angles makes the formalism rather simple.

25 With appropriate parameters, the stimulated echo sequence of the invention is robust against susceptibility effects. According to the invention, the stimulated echo sequence with acquisition of the FID signals and the stimulated echo signals is used as a SENSE reference scan for MR imaging near metal. The sequence of the invention is robust against susceptibility effects and provides RF coil sensitivity information within seconds. This 30 enables robust SENSE to accelerate multispectral MR imaging with the use of a fast SENSE reference scan.

In addition to RF receive coil sensitivity information, the sequence of the invention also provides information about B_0 distribution and transmit B_1 distribution.

An MR image can be reconstructed from the FID signals and another MR image can be reconstructed from the stimulated echo signals. After the MR image reconstruction, a transmit B_1 map can be derived from the voxel-wise intensity ratio of the two MR images reconstructed from the FID and stimulated echo signals, respectively. A 5 plurality of FID signals and stimulated echo signals with appropriate phase encoding need to be acquired for generating a complete B_1 map (receive and/or transmit sensitivities).

According to another preferred embodiment of the invention, a B_0 map indicating the spatial distribution of the main magnetic field within the portion of the body is derived from the acquired FID and stimulated echo signals as well. It turns out that, by using 10 appropriate parameters of the imaging sequence, not only a B_1 map, but also a B_0 map can be derived from the voxel-wise intensities of the FID and stimulated echo signals. It is an advantage of the invention that a B_1 map and a B_0 map can be acquired simultaneously without additional measurement steps. Therefore, as an additional value of the invention, without any additional scan time, the B_0 distribution information of the sequence can be used 15 for automated determination of the required frequency coverage of subsequent diagnostic scans. The (multispectral) scan protocol can then (automatically) be adapted to meet this required frequency coverage in the minimal required scan duration. As the B_0 distribution is spatially dependent, it's even possible, if desired, to adapt the (multispectral) scan protocol to meet the required frequency coverage per slice.

20 In accordance with a preferred embodiment of the invention, the FID and the stimulated echo signals are acquired as gradient-recalled echo signals. The timing of the sequence can be adjusted such that susceptibility- and chemical shift-induced effects are essentially equal for both the FID and stimulated echo signals.

According to still another preferred embodiment of the invention, the proposed 25 approach can be used for volumetric acquisitions. For volumetric applications, a multi-slice version of the proposed technique is advantageous. Therein, an appropriate slice order (e.g. measurement of the odd slices in a 3D stack in a first step and then the even ones in a subsequent measurement step), seems to be useful to avoid potential slice cross-talk. To ease the signal evaluation, as described below, the two preparation RF pulses of the stimulated 30 echo sequence may excite a broader slice, (preferably with a slice thickness increased by a factor of two) than the reading RF pulses. This helps to avoid problems associated with imperfect slice profile excitation in signal evaluation for B_1 mapping.

According to a further preferred embodiment of the invention, the at least two preparation RF pulses each have a flip angle of 45°-90°. In this way, the amplitudes of the

acquired stimulated echo signals are maximized which is advantageous in terms of signal-to-noise.

According to another preferred embodiment of the invention, a plurality of FID and stimulated echo MR signals are generated by means of a plurality of consecutive 5 reading RF pulses, each having a flip angle of less than 90°, preferably less than 45°, most preferably less than 30°. As already mentioned above, a train of reading RF pulses having small flip angles can be used to achieve a fast readout of multiple FID and stimulated echo signals. Echo times as short as possible can be used to minimize T_2^* relaxation.

According to yet another preferred embodiment of the invention, switched 10 magnetic field gradients are applied during the preparation period after the two-preparation RF pulses in order to spoil residual nuclear magnetization.

According to still another preferred embodiment of the invention, the FID signals and/or the stimulated echo signals are acquired via the at least two RF coils having different spatial receive sensitivity profiles and, in parallel or sequentially, via at least one 15 volume RF coil having a substantially homogeneous spatial sensitivity profile within the examination volume, wherein the spatial receive sensitivity profiles of the RF coils are derived by comparing the signals acquired via RF coils having different spatial sensitivity profiles with the signals acquired via the volume RF coil. For example, the signal acquisition according to the invention may be repeated, at least two times, in the first acquisition using 20 the volume RF coil for reception in the second using the RF coils having different spatial sensitivities. In an alternative approach, the RF coils to be used for MR signal acquisition can be switched during a stimulated echo read-out according to the invention. In this way, motion artefacts can be reduced, when the data interleaving process also checks for signal 25 inconsistencies. Moreover, the receive RF coil sensitivity mapping can be performed according to the invention in a single acquisition step, using the volume RF coil and the RF coils having different receive sensitivity profiles (e.g. array RF coils) simultaneously, provided a sufficient RF coil decoupling can be achieved.

According to a further preferred embodiment of the invention, the parameters 30 of the first imaging sequence are selected such that the temporal spacing between the two preparation RF pulses equals the echo time of the stimulated echo. This timing scheme preserves the spin echo properties of the stimulated echo. Hence, spatial phase variations due to static inhomogeneities of the main magnetic field are fully compensated by refocusing of the spin phases, allowing to derive metal-resistant spatial sensitivity profiles of the RF coils from the stimulated echo signals. The determination of a B_1 map and a B_0 map remains

possible, except for the vicinity of the metal parts, where the strong susceptibility effects may degrade the FID signal. In case of strong susceptibility effects, the signal analysis for deriving the spatial sensitivity profiles should be based only on the stimulated echo signals. If metal implants or other sources of strong main magnetic field changes are not present, 5 additionally also the FID signals can be used to estimate the RF receive coil sensitivity profiles in order to improve the signal-to-noise ratio.

In a preferred embodiment, the method of the invention further comprises the steps of:

- subjecting the portion of the body to a second imaging sequence of RF pulses and switched magnetic field gradients;
- acquiring a MR signal data set by means of parallel signal acquisition via the at least two RF coils with sub-sampling of k-space; and
- reconstruction of a MR image from the MR signal data set and from the spatial sensitivity profiles of the at least two RF coils.

15 In this embodiment of the invention, the final (diagnostic) MR image is reconstructed, for example by using the SENSE algorithm, from the MR signal data set acquired by parallel (i.e. accelerated) imaging using sub-sampling and from the spatial sensitivity profiles derived from the simulated echo acquisition. In order to enable fast imaging, the image resolution of the first imaging sequence (reference scan) can be chosen to 20 be lower than the image resolution of the second imaging sequence (diagnostic scan). The reference scan may be performed prior to or after the diagnostic scan.

25 In accordance with another preferred embodiment of the invention, the second imaging sequence is a multispectral imaging sequence. The above referenced multispectral imaging techniques like SEMAC and MAVRIC can be used in order to enable MR imaging near metal parts. The scan duration can be kept within reasonable limits by using SENSE in combination with the stimulated echo reference scan, which is fast and robust against susceptibility effects according to the invention.

The method of the invention described thus far can be carried out by means of 30 a MR device including at least one main magnet coil for generating a uniform steady magnetic field within an examination volume, a number of gradient coils for generating switched magnetic field gradients in different spatial directions within the examination volume, at least one RF coil for generating RF pulses within the examination volume and/or for receiving MR signals from a body of a patient positioned in the examination volume, a control unit for controlling the temporal succession of RF pulses and switched magnetic field

gradients, and a reconstruction unit for reconstructing MR images from the received MR signals. The method of the invention is preferably implemented by a corresponding programming of the reconstruction unit and/or the control unit of the MR device.

The methods of the invention can be advantageously carried out in most MR devices in clinical use at present. To this end it is merely necessary to utilize a computer program by which the MR device is controlled such that it performs the above-explained method steps of the invention. The computer program may be present either on a data carrier or be present in a data network so as to be downloaded for installation in the control unit of the MR device.

10

BRIEF DESCRIPTION OF THE DRAWINGS

The enclosed drawings disclose preferred embodiments of the present invention. It should be understood, however, that the drawings are designed for the purpose of illustration only and not as a definition of the limits of the invention. In the drawings:

15

Fig. 1 schematically shows a MR device for carrying out the methods of the invention;

Fig. 2 shows a diagram illustrating a first imaging sequence according to the invention.

20

DETAILED DESCRIPTION OF EMBODIMENTS

With reference to Figure 1, a MR device 1 is shown. The device comprises superconducting or resistive main magnet coils 2 such that a substantially uniform, temporally constant main magnetic field B_0 is created along a z-axis through an examination volume. The device further comprises a set of (1st, 2nd, and - where applicable - 3rd order) shimming coils 2', wherein the current flow through the individual shimming coils of the set 2' is controllable for the purpose of minimizing B_0 deviations within the examination volume.

A magnetic resonance generation and manipulation system applies a series of RF pulses and switched magnetic field gradients to invert or excite nuclear magnetic spins, induce magnetic resonance, refocus magnetic resonance, manipulate magnetic resonance, spatially and otherwise encode the magnetic resonance, saturate spins, and the like to perform MR imaging.

More specifically, a gradient pulse amplifier 3 applies current pulses to selected ones of whole-body gradient coils 4, 5 and 6 along x, y and z-axes of the examination volume. A digital RF frequency transmitter 7 transmits RF pulses or pulse

packets, via a send-/receive switch 8, to a -body RF coil 9 to transmit RF pulses into the examination volume. A typical MR imaging sequence is composed of a packet of RF pulse segments of short duration which taken together with each other and any applied magnetic field gradients achieve a selected manipulation of nuclear magnetic resonance. The RF pulses 5 are used to saturate, excite resonance, invert magnetization, refocus resonance, or manipulate resonance and select a portion of a body 10 positioned in the examination volume.

For generation of MR images of regions of the body 10 by means of parallel imaging, a set of local array RF coils 11, 12, 13 are placed contiguous to the region selected for imaging. The array RF coils 11, 12, 13 can be used to receive MR signals induced by 10 body-coil RF transmissions.

The resultant MR signals are picked up by the body RF coil 9 and/or by the array RF coils 11, 12, 13 and demodulated by a receiver 14 preferably including a preamplifier (not shown). The receiver 14 is connected to the RF coils 9, 11, 12 and 13 via send-/receive switch 8.

15 A host computer 15 controls the current flow through the shimming coils 2' as well as the gradient pulse amplifier 3 and the transmitter 7 to generate any of a plurality of MR imaging sequences, such as echo planar imaging (EPI), echo volume imaging, gradient and spin echo imaging, fast spin echo imaging, and the like. For the selected sequence, the receiver 14 receives a single or a plurality of MR data lines in rapid succession following 20 each RF excitation pulse. A data acquisition system 16 performs analog-to-digital conversion of the received signals and converts each MR data line to a digital format suitable for further processing. In modern MR devices the data acquisition system 16 is a separate computer which is specialized in acquisition of raw image data.

25 Ultimately, the digital raw image data is reconstructed into an image representation by a reconstruction processor 17 which applies appropriate reconstruction algorithms, such like SENSE. The MR image may represent a planar slice through the patient, an array of parallel planar slices, a three-dimensional volume, or the like. The image is then stored in an image memory where it may be accessed for converting slices, projections, or other portions of the image representation into appropriate format for visualization, for 30 example via a video monitor 18 which provides a man-readable display of the resultant MR image.

Figure 2 shows a schematic diagram illustrating a first imaging sequence according to the invention which is applied as a SENSE reference scan. The depicted imaging sequence is a stimulated echo sequence which is subdivided into a preparation

period 21 and an acquisition period 22. Two preparation RF pulses having a flip angle of α are applied during the preparation period 21. The two preparation RF pulses are separated by a time interval T_E . A de-phaser magnetic field gradient G_{mc2} is applied between the two preparation RF pulses. A sequence of reading RF pulses having flip-angle β are generated 5 during the acquisition period 22, which is temporally subsequent to the preparation period 21. An FID signal I_1 and a stimulated echo signal I_2 are acquired after each reading pulse as gradient-recalled echoes.

Directly after the preparation sequence 21, the longitudinal magnetization is given by:

$$M_{z1} = \cos^2(\alpha) \cdot M_0$$

$$M_{z2} = \frac{1}{2} \sin^2(\alpha) \cdot M_0,$$

wherein M_{z1} and M_{z2} denote the un-prepared (i.e. in-phase) and the stimulated echo-prepared (i.e. de-phased) longitudinal magnetization, respectively. In accordance with the invention, both the FID signal I_1 generated from M_{z1} and the stimulated echo signal I_2 generated from M_{z2} are acquired at different points in time $TE1$ and $TE1 + T$, respectively. The delay

15 T between the two echoes I_1, I_2 is determined by the relation:

$$\Delta T = A_{mc2} / G_m,$$

wherein A_{mc2} denotes the gradient-time area of the de-phaser gradient G_{mc2} and G_m denotes the strength of the readout magnetic field gradient.

According to the invention, the timing scheme $TE = TE1 + \Delta T$ can be employed,

20 which fully preserves the spin echo properties of the stimulated echo. Hence, static inhomogeneities of the main magnetic field B_0 are fully refocused, allowing metal-resistant SENSE reference scan data to be derived from the stimulated echo signal I_2 .

If the MR signal acquisition by means of the first imaging sequence is repeated, at least two times, in the first acquisition using the body RF coil 9 for reception in 25 the second using the array RF coils 11, 12, 13, the receive RF coil sensitivity profiles can be derived. In case of strong susceptibility effects, the corresponding signal analysis should be based only on the stimulated echo signal I_2 .

The (unknown) flip angle α of the stimulated echo preparation RF pulses (and thus the transmit B_1 map of the used transmit coil) can be derived from the ratio of the 30 acquired echo signals according to:

$$\alpha = \arctan \sqrt{2|I_2/I_1|}$$

The mirrored phase of the stimulated echo signal I_2 may be further employed to derive a B_0 phase map:

$$\phi_{B_0} = \arg(I_1 \cdot I_2^*)$$

After application of the first imaging sequence as a SENSE reference scan, a 5 second imaging sequence (not depicted) is performed as a diagnostic scan with sub-sampling of k-space. The corresponding diagnostic MR image is then reconstructed, by using the SENSE algorithm, from the MR signal data set acquired during the diagnostic scan and from the spatial sensitivity profiles derived from the stimulated echo acquisition of the reference scan. The second imaging sequence can be a multispectral imaging sequence in order to 10 improve MR image quality near metal parts. Though multispectral imaging sequences are typically associated with long scan durations, the scan duration is kept within reasonable limits by using SENSE parallel imaging in combination with the stimulated echo reference scan, which is fast and robust against susceptibility effects.

The afore-described technique of the invention improves the applicability of 15 MR imaging near metal, which may be part of but not limited to: cobalt-chrome, titanium, stainless steel, zirconium oxide. Application areas include, for example, diagnosis in the following cases:

Evaluation of post-operative complications, including infections, integrity of surrounding soft tissue in the presence of metal objects that may include orthopedic implants for e.g. knee, hip, 20 rib, ankle, or oncology bone reconstruction, fixing plates, screws, stents or MR safe implanted electrodes, etc.

- Application of super-paramagnetic agents (e.g. iron disposition).

Diagnostic imaging in the presence of bullets or shrapnel, e.g. resulting from surgery, trauma, profession in metal processing industry etc.

25 Therapy applications of the method of the invention include imaging in the proximity of interventional instruments, for example seeds implanted for brachytherapy, needle tracking for biopsy or deep brain stimulation, and other areas in which susceptibility artefacts limit the quality and thus the value of MR images.

CLAIMS:

1. Method of MR imaging of at least a portion of a body (10) placed within the examination volume of a MR device (1), the method comprising the steps of:

- subjecting the portion of the body (10) to a first imaging sequence of RF pulses and switched magnetic field gradients, which imaging sequence is a stimulated echo sequence including:

5 i) at least two preparation RF pulses (α) radiated toward the portion of the body (10) during a preparation period (21), and

10 ii) one or more reading RF pulses (β) radiated toward the portion of the body (10) during an acquisition period (22) temporally subsequent to the preparation period (21);

- acquiring one or more FID signals (I_1) and one or more stimulated echo signals (I_2) during the acquisition period (22) by means of parallel signal acquisition via at least two RF coils (11, 12, 13) having different spatial sensitivity profiles within the examination volume; and

15 - deriving the spatial sensitivity profiles of the at least two RF coils (11, 12, 13) from the acquired FID signals (I_1) and/or from the acquired stimulated echo signals (I_2).

2. Method of claim 1, wherein a B_1 map indicating the spatial distribution of the RF field of the RF pulses is derived from the acquired FID (I_1) and stimulated echo (I_2) signals.

20 3. Method of claim 1 or 2, wherein the at least two preparation RF pulses (α) each have a flip angle of 45°-90°.

25 4. Method of any one of claims 1-3, wherein a plurality of FID signals (I_1) and stimulated echo signals (I_2) are generated by means of a corresponding plurality of consecutive reading RF pulses (β), each having a flip angle of less than 90°, preferably less than 45°, most preferably less than 30°.

5. Method of any one of claims 1-4, wherein a B_0 map indicating the spatial distribution of the main magnetic field is derived from the acquired FID (I_1) and stimulated echo (I_2) signals.

5 6. Method of any one of claims 1-5, wherein the FID signals (I_1) and/or the stimulated echo signals (I_2) are acquired via the at least two RF coils (11, 12, 13) having different spatial receive sensitivity profiles and via at least one volume RF coil (9) having a substantially homogeneous spatial sensitivity profile within the examination volume, wherein the spatial sensitivity profiles of the RF coils (11, 12, 13) are derived by comparing the 10 signals (I_1, I_2) acquired via the RF coils (11, 12, 13) having different spatial sensitivity profiles with the signals (I_1, I_2) acquired via the volume RF coil (9).

7. Method of any one of claims 1-6, wherein the parameters of the first imaging sequence are selected such that the temporal spacing between the two preparation RF pulses 15 (α) equals the echo time of the stimulated echo.

8. Method of any one of claims 1-7, further comprising the steps of:
- subjecting the portion of the body (10) to a second imaging sequence of RF pulses and switched magnetic field gradients;
20 - acquiring a MR signal data set by means of parallel signal acquisition via the at least two RF coils (11, 12, 13) with sub-sampling of k-space; and
- reconstruction of a MR image from the MR signal data set and from the spatial sensitivity profiles of the at least two RF coils (11, 12, 13).

25 9. Method of claim 8, wherein the MR image is reconstructed by using the SENSE or SMASH or GRAPPA algorithm.

10. Method of claim 8 or 9, wherein the second imaging sequence is a multispectral imaging sequence.

30

11. MR device comprising at least one main magnet coil (2) for generating a uniform, steady magnetic field within an examination volume, a number of gradient coils (4, 5, 6) for generating switched magnetic field gradients in different spatial directions within the examination volume, at least one RF coil (9) for generating RF pulses within the examination

volume, at least two RF coils (11, 12, 13) having different spatial sensitivity profiles within the examination volume for receiving MR signals from at least a portion of a body (10) of a patient positioned in the examination volume, a control unit (15) for controlling the temporal succession of RF pulses and switched magnetic field gradients, and a reconstruction unit (17) for reconstructing MR images from the received MR signals, wherein the MR device (1) is arranged to perform the following steps:

- subjecting the portion of the body (10) to a first imaging sequence of RF pulses and switched magnetic field gradients, which imaging sequence is a stimulated echo sequence including:
 - 10 i) at least two preparation RF pulses (α) radiated toward the portion of the body (10) during a preparation period (21), and
 - ii) one or more reading RF pulses (β) radiated toward the portion of the body (10) during an acquisition period (22) temporally subsequent to the preparation period (21);
- 15 - acquiring one or more FID signals (I_1) and one or more stimulated echo signals (I_2) during the acquisition period (22) by means of parallel signal acquisition via the at least two RF coils (11, 12, 13); and
- deriving the spatial sensitivity profiles of the at least two RF coils (11, 12, 13) from the acquired FID signals (I_1) and/or from the acquired stimulated echo signals (I_2).

20

12. Computer program to be run on a MR device (1), which computer program comprises instructions for:

- generating a first imaging sequence of RF pulses and switched magnetic field gradients, which imaging sequence is a stimulated echo sequence including:
 - 25 i) at least two preparation RF pulses (α) generated during a preparation period (21), and
 - ii) one or more reading RF pulses (β) generated during an acquisition period (22) temporally subsequent to the preparation period (21);
- acquiring one or more FID signals (I_1) and one or more stimulated echo signals (I_2) during the acquisition period (22) by means of parallel signal acquisition via at least two RF coils (11, 12, 13); and
- deriving the spatial sensitivity profiles of the at least two RF coils (11, 12, 13) from the acquired FID signals (I_1) and/or from the acquired stimulated echo signals (I_2).

INTERNATIONAL SEARCH REPORT

International application No
PCT/IB2013/058447

A. CLASSIFICATION OF SUBJECT MATTER
INV. G01R33/24
ADD.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
G01R

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

EPO-Internal

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	<p>ZHANG Q ET AL: "Improving True-FISP Parallel Cine Imaging using a New Data-acquisition Scheme for Coil Sensitivity Calibration", INTERNATIONAL SOCIETY FOR MAGNETIC RESONANCE IN MEDICINE. SCIENTIFIC MEETING AND EXHIBITION. PROCEEDINGS, INTERNATIONAL SOCIETY FOR MAGNETIC RESONANCE IN MEDICINE, US, 1 January 2003 (2003-01-01), page 2329, XP002316861, ISSN: 1524-6965 the whole document</p> <p style="text-align: center;">-----</p> <p style="text-align: center;">-/-</p>	1,3,4, 6-9,11, 12

Further documents are listed in the continuation of Box C.

See patent family annex.

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance
"E" earlier application or patent but published on or after the international filing date
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
"O" document referring to an oral disclosure, use, exhibition or other means
"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family
