Textile hose

The present invention relates to a textile hose for encasing elongated objects.

EP 1 685 285 B1 discloses a radially shrinkable textile fabric hose which is woven in two layers, with an upper and a lower fabric layer, the fabric layers being joined together at their edges with binding warp threads and thus forming a hose. Such hoses are used, for example, in the area of automotive technology for mechanical reinforcement and for increasing the wear resistance of pipes and tubes. For this purpose, they are pulled over elongated objects such as pipes, tubes and also foam pipes and then shrunk. This then provides protection against mechanical abrasion. In addition, there is the use of foam pipes, e.g. EPDM foam pipes for insulation. In practice, foam tubes are currently used, e.g. EPDM-based, to protect pipes in the car against heat losses or the effects of cold. On the one hand, these may be pipes carrying a medium, e.g. coolants. Likewise, electrical wiring harnesses are also sheathed with them. One of the purposes of insulation is to prevent possible loss of power in the drive system of a motor vehicle which may occur as a result of heat loss. On the one hand the EPDM foam pipes mentioned above have a high insulation capacity, but on the other hand they are extremely susceptible to mechanical effects, e.g. abrasion.

In automotive construction and in other applications, however, there are elongated objects, e.g. in the engine compartment of cars or pipes made from polyamide for transporting coolants, which must always be protected against thermal influences. Therefore, even during the installation of sheaths, they must not be exposed to any thermal stress. In this respect, textile fabric hoses which can be shrunk on by heating are not suitable or only suitable to a limited extent.

Due to increasingly tighter installation spaces in automotive construction, there is a high probability that foam pipes used in the engine compartment of a motor vehicle for thermal insulation will come into contact with other, for example hot or abrasive, components. Depending on the intensity of the contact, high abrasive forces may act on the foam pipe which can lead to rapid destruction of the foam pipe and thus severely limit the insulation effect.

The object of the present invention is thus to propose a textile hose for encasing elongated objects which now avoids or at least greatly diminishes the known disadvantages in prior art.

The object is achieved with a hose according to claim 1, namely a textile hose for encasing elongated objects which is characterised by the following features:

- a) a radially elastic outer layer made from wear-resistant material and
- b) at least one inner layer made from thermally insulating material. Such a hose according to the invention – with defined thermal conductivity and simultaneously high mechanical resistance against abrasion – can be fitted on abrasion-prone elongated objects that are to be thermally insulated. They may be rods, tubes, wiring harnesses, pipes, profiles and piping in particular made from polyamide which need not necessarily be stretched out but may show any kinks. The hose can be easily expanded in a single operation, pulled onto the elongated object and firmly fixed essentially immovably in the desired position. Advantageously, this means there is no need to subsequently fit a plurality of layers one over the other as disclosed in prior art. It also prevents the damage to an abrasion-prone insulation layer, e.g. EPDM foam pipe. The term “radially elastic outer layer” means that the outer layer of the sheath tends to narrow the hose radially due to its radially elastic structure. Of course, for this purpose the outer layer has the property according to the invention of shortening in the circumferential direction in order to bring about a narrowing in the radial direction.

To keep the assembly effort during fabrication as low as possible, the protective hose can preferably be fitted in the production section in a single operation. For this reason, the textile hose according to the invention is favoured as its multi-layer structure can be produced in a single operation, thus eliminating the need for a great deal of assembly effort resulting from subsequently fitting a plurality of layers one over the other.

In an advantageous embodiment of the invention, the hose is designed in such a manner that the outer layer and the at least one inner layer are joined together in places by a textile binding, by sewing or by bonding. This embodiment additionally makes it easier to fit the hose according to the invention as its two layers cannot move against each other and separate from each other when being pulled on. This makes assembly safer and more reliable.

In yet another advantageous embodiment of the invention, the hose is designed in such a manner that the outer layer and the at least one inner layer are constructed as woven fabric, weft-knitted fabric, warp-knitted fabric or braided fabric. This advantageously permits very cost-efficient production of the hose according to the invention. Due to the combination of a wear-resistant textile outer layer with one or a plurality of inner layers made from thermally insulating material, a hose can be created which is simultaneously wear-resistant and has a high insulation effect. The hose can be used specifically on sensitive smooth plastic pipes, onto which no hoses can be shrunk by heat due to their low heat resistance.

If, for example, the hose is woven, an elastic weft thread made from silicone rubber (silicone elastic), as is disclosed for example in EP 2 352 613 B1, gives the hose high elasticity, or flexibility, in the radial direction with the best rebound properties which make it possible to easily install the hose on the elongated object with a subsequently tight fit.

In yet another advantageous embodiment of the invention, the hose is designed in such a manner that it has multifilament threads running axially and elastic threads and multifilament threads running circumferentially. On the one hand, it is possible to control the thermal conductivity of the hose by adding multifilament threads running circumferentially which, for example, extend floatingly with the elastic threads. On the other hand, it is possible to influence the elastic contraction of the hose. In addition, this advantageous development results in more uniform structures. Sliding on and puffing up the multifilament threads running circumferentially when contracting the hose around the elongated object prevents so-called warp gaps. The stability of the hose increases advantageously.

In another advantageous embodiment of the invention, the hose is designed in such a manner that the outer layer is coated or impregnated with an agent which increases the wear resistance. With this advantageous measure, it is possible to achieve the individually desired lifetime of the hose according to the invention.

In yet another advantageous embodiment of the invention, the hose is designed in such a manner that the at least one inner layer is coated or impregnated with an agent which increases the thermal conductivity. With this advantageous measure, it is possible to increase the individually desired insulation capability of the hose according to the invention.

These agents referred to above correspond to finishing liquors known from prior art. These agents for increasing the thermal conductivity, mechanical resistance or cold cutting ability may be applied, for example by padding, doctor coating or spraying.

In yet another advantageous embodiment of the invention, the hose is designed in such a manner that it consists at least partially of finished threads. This embodiment has the advantage that, depending on the need for optimisation with regard to thermal conductivity, mechanical resistance and cold cutting ability for the desired application, individually treated threads positively influence the performance of the hose according to the invention.

In another advantageous embodiment of the invention, the hose is designed in such a manner that the at least one inner layer is wetted internally with an adhesive or a glue. This makes it possible to further enhance secure attachment of the hose according to the invention to the selected elongated object, particularly when used in a vibrating environment.

In another advantageous embodiment of the invention, the hose is designed in such a manner that the at least one inner layer is formed in the form of ribbons, in particular made from foam material. Within the inner layer in the form of ribbons, it is advantageously possible to increase the entrapped air compared to a regular thread, thus further increasing the insulating effect.

To facilitate understanding of the invention and to show how it can be embodied, it will now be briefly explained by way of an example embodiment with the aid of a drawing, in which:

Fig. 1 is a greatly simplified diagrammatic perspective view of a section of a hose according to the invention cut lengthwise and approximately centrally, arranged around an elongated object and already partially contracted thereabout.

Fig. 2 is a diagrammatic view of a cross-section through the textile hose with a detail X.

Fig. 3 is a greatly simplified diagrammatic perspective view of a section of an embodiment of a hose according to the invention.

Fig. 4 is a greatly simplified diagrammatic perspective view of a section of a hose according to the invention cut lengthwise and approximately centrally, similar to Fig. 1 without elongated object.

Fig. 5 is a greatly simplified diagrammatic perspective view of a section of a textile hose according to the invention with longitudinal chambers.

Fig. 1 shows a hose 10 according to the invention cut lengthwise and approximately centrally, having an outer layer 2 and an inner layer 4. The outer layer 2 is intended to represent an abrasion-resistant sheath which surrounds the insulating inner layer 4. In a region III, the hose 10 is shown already contracted around an elongated object, here a pipe 1 for example, due to its radially elastic structure.

In regions I and II, the hose 10 still has an inner diameter which is greater than the outer diameter of the pipe 1. At the beginning of fitting, the hose 10 according to the invention which has been expanded to a diameter in accordance with region I, for example by means of a device (not shown), is pushed onto the pipe 1, with the result that it contracts due to the radial elasticity of the outer layer 2, as the transition in region II is intended to show, and attaches to the pipe 1. In region III, the hose 10 is already fully contracted radially and sits tightly on the pipe 1. It is easy to see that the insulating inner layer 4 is thicker than the abrasion-resistant outer layer 2.

In region III, the hose 10 is already contracted and sits tightly on the pipe 1, the insulating inner layer 4 fitting closely. An adhesive can also be applied between insulating layer 4 and pipe 1 to fix the hose even more securely to the pipe 1.

The contraction process is to be typified in region II. The diameter of the textile hose 10 reduces, while at the same time the wall thickness of the insulating inner layer 4 and the wear-resistant outer layer 2 increases.

Advantageously, the thermally insulating inner layer 4 has a wall thickness of between 0.5 and 6 mm. The function of the wear-resistant outer layer 2 of the textile hose 10 is to protect the insulating inner layer 4 against mechanical effects from the outside.

Fig. 2 shows, for example, a hose 10 according to the invention executed here as a transverse-oval, with an outer layer 2 and an inner layer 4 which are joined together by means of a plurality of bindings 26, e.g. in the form of a woven binding or a basting stitch or a braided connection. When using a plurality of layers of insulating inner layers 4 as referred to above, the binding 26 may also be arranged therebetween. The bindings 26 extend not only circumferentially in the textile hose 10 but also in the longitudinal direction thereof in order to achieve a uniform interconnection of the individual layers. These bindings 26 are preferably created by interweaving during manufacture of the textile hose 10. The hose 10 according to the invention may be manufactured by weaving, warp-knitting, weft-knitting or braiding. Subsequent fixing by means of adhesive technology or by sewing the individual layers would also be conceivable as ties 26. The arrangement of a tie 26 is shown enlarged in Fig. 2, bottom right.

Fig. 3 shows a diagrammatic illustration of a textile hose 50 as it is after finishing with an expedient finishing liquor to improve the thermal conductivity, mechanical resistance or. Here a detail of the textile hose 50 is enlarged to show that the finishing liquor (that is a fluid for treating or finishing a textile object, see above), hereinafter referred to as a "coating", impregnates the textile hose 50. Here the reference number 60 indicates, for example, textile layers of the hose which are completely impregnated, while reference number 70 is intended to indicate textile layers in their unfinished form (before the application of a finishing liquor).

It would also be conceivable to wet only the surface of the textile hose superficially and thus to dispense with completely impregnating the entire textile hose. Due to superficial wetting, the finishing (finishing liquor) does not "stiffen" the inner layers which preserves the bulkiness of the threads of the inner layer and allows better insulation values to be achieved. In addition, there is the advantage that finishing material can be saved.

Fig. 4 is a greatly simplified diagrammatic perspective view of a section of a hose according to the invention cut lengthwise and approximately centrally, similar to Fig. 1.

Fig. 5 is a greatly simplified diagrammatic perspective view of a section of a textile hose 20 according to the invention with a radially elastic outer layer 22 and an inner layer 24, as well as with longitudinal chambers 21 situated therebetween which are partially filled with filler threads 23. The inner layer 24 surrounds an interior space 27 in which elongated objects (not shown), such as pipes, tubes, cables, etc., may find space, or which may be encased with the hose 20 according to the invention. If the hose 20 according to the invention is "pulled on" around an elongated object (Fig. 1), it contracts so that it fits tightly around the elongated object. Advantageously, the inner surface 29 of the inner layer 24 may also be provided with an adhesive, via which even better adhesion of the hose 20 to the elongated object can be achieved. Some of the filled chambers 21 in the embodiment according to Fig. 5 contain filling material 23 in the form of threads, ribbons, preferably made from foam material, by means of which the insulation capacity of the tube 20 can increase considerably.

The outer layer 22 and the inner layer 24 of the hose 20 according to the invention are woven, for example, as shown in Fig. 5 and joined together in the region of zones 12 via e.g. woven bindings 26. Chambers 21 are arranged between the zones 12 extending longitudinally. On the outside of the outer layer 22 are threads of a plain weave L 1/1, as indicated by - | - | - | - | - | -, in which the hose 20 according to the invention, for example, is woven. However, other weaving patterns may also be used. The hose, however, may also be weft-knitted, braided or warp-knitted. The radially elastic outer layer 22 consists of wear-resistant material and the inner layer 24 of thermally insulating material.

Filler threads 23, which are arranged in the chambers 21, are used in addition for thermal insulation of the inner layer 24. Fig. 5, top right, shows an "exposed" "filling" of a chamber 21 in the form, for example, of crimped threads 23. For this purpose, the corresponding chamber is shown cut away at the point "S". However, it is also possible to use a plurality of other filling materials. A chamber 211 is filled, for example, with stretched threads 231 which are shown "exposed" at the point 123. In addition, tubes, any suitable thermal insulating material, even in fleece or ribbon form, may be used. The present embodiment shows a hose 20 with an inner layer 24. According to the invention, however, a plurality of inner layers 24 may also be arranged on top of or inside each other like onion skins, in order, for example, to increase the thermal insulation capacity of the hose 20.

Claims

1. A textile hose for encasing elongated objects, the textile hose comprising the following features:
 - a) a radially elastic outer layer made from wear-resistant material and
 - b) at least one inner layer made from thermally insulating material,the outer layer and the at least one inner layer being joined together in places by one of interweaving, sewing and bonding,

the outer layer and the at least one inner layer additionally being joined together along zones extending axially, the zones being radially spaced apart from one another,

wherein, between the outer layer and the at least one inner layer, chambers are situated between the zones, and wherein filling material in the form of one of threads, ribbons and foam, is arranged between the outer layer and the at least one inner layer in a region of the chambers.
2. The textile hose according to claim 1, wherein the outer layer and the at least one inner layer are each constructed as one of woven fabric, weft-knitted fabric, warp-knitted fabric and braided fabric.
3. The textile hose according to any one of claims 1 and 2, wherein the textile hose has multifilament threads running axially, and elastic threads and multifilament threads running circumferentially.
4. The textile hose according to any one of claims 1 to 3, wherein the outer layer is one of coated and impregnated with an agent which increases wear resistance.
5. The textile hose according to claim 1, wherein the textile hose consists at least partially of finished threads.
6. The textile hose according to claim 1, wherein the at least one inner layer is wetted internally with one of an adhesive and a glue.
7. The textile hose according to claim 1, wherein the at least one inner layer is formed from one of ribbons and foam material.

8. The textile hose according to claim 1, wherein the textile hose has a thermal conductivity $\leq 0.3 \text{ W/m} \times \text{K}$.
9. The textile hose according to claim 1, wherein the textile hose has a wall thickness ranging from 1 to 8 mm.
10. The textile hose according to claim 1, wherein the outer layer has an elastic weft thread made from silicone rubber.
