UNITED STATES PATENT OFFICE.

GEORGE EUGENE MITTINGER, OF YOUNGSTOWN, OHIO.

THREE-PIECE METALLIC SHIPPING-BARREL.

1,376,216.

Specification of Letters Patent.

Patented Apr. 26, 1921.

Application filed May 18, 1920. Serial No. 382,326.

To all whom it may concern:

Be it known that I, GEORGE E. MITTINGER, a citizen of the United States, residing at Youngstown, in the county of Mahoning and State of Ohio, have invented certain new and useful Improvements in Three-Piece Metallic Shipping-Barrels, of which the following is a specification, reference being had therein to the accompanying drawing.

10 This invention relates to improvements in a three-piece metallic shipping barrel, so constructed that when its parts are separated, they will nest one within the other for empty return shipment, whereby the 15 knock-down barrel occupies about one-third of the shipping space of the assembled barrel.

The primary object of my present improvement is to provide a knock-down nestable metallic barrel, comprising a central section and two end sections, so constructed that the end sections may be closely nested one within the other and the two nested within the central section, whereby the 25 knock-down barrel occupies approximately one-third of the shipping space of the assembled barrel.

Another object of my invention is to provide a three-section knock-down nestable barrel, the central section having its opposite ends provided with peripheral annular laterally extending flanges, and the end sections having their inner ends provided with annular laterally projecting flanges coöperating with the flanges of the central section to receive between them a packing ring, and a sectional clamping ring embracing the flanges that clamp them tightly together and compress the packing whereby a rigid 40 liquid-tight barrel is provided.

A further object of my invention is to provide a sectional barrel having the center and end sections with flanges as described in the immediately foregoing paragraph, and sectional rings having at their inner faces U-shaped grooves to clamp the flanges and hold the sections tightly together and at the same time act as rolling hoops for the barrel and as a protection to 50 the flanges of the three sections.

A further object of my improvement comprises a center and two end sections consist-

ing in making one end section of a diameter smaller than the diameter of the central section about equal to the thickness of the material, whereby that end section may be nested within the central section, and to make the other end section of a diameter smaller than the first end section about equal to the thickness of the material whereby it can be nested within the first said end section, and both end sections closely nested within the central section.

A further object of my invention is to so construct the clamping bands that when the three sections of the barrel are nested, the clamping bands or hoops will receive the flanges of the nested parts and also the packing, so that all the parts for the complete barrel are held in their nested positions with all the necessary parts for assembling into a rigid liquid-tight barrel.

Further objects of my present invention will appear from the following description.

In the accompanying drawings:

Fig. 1 is a side elevation of my improved three-section shipping barrel.

Fig. 2 is a longitudinal section through one side of the barrel.

Fig. 3 is an enlarged section through the 80 adjacent ends of the larger end section and central section and the clamping ring in position for drawing the parts tightly together.

Fig. 4 is a sectional view through the adjacent ends of the central section and smaller end section showing the clamping ring drawn to clamping position and the packing compressed between the annular lateral flanges of the two sections.

Fig. 5 is a longitudinal sectional view showing the three sections of the barrel, the clamping rings and the packings in position for return shipment.

Fig. 6 is a side elevation of the central 95 section.

Fig. 7 is a top plan view of two of the meeting ends of the clamping ring, showing it in position on the adjacent flanges of the central and end sections.

Fig. 8 is a side elevation at right angles to Fig. 7.

Metallic barrels are extensively used for shipping liquids and are recognized by the

trade as the best form of barrel for that purpose. They are too expensive to discard and because of their bulkiness the return freight on them is expensive. Especially is this true where the freight is reckoned on space occupied, such as in shipping, rather than weight. Therefore, there has for a long time been a demand for a mechanically practical knock-down nestable shipping barrel which will occupy the least possible space without sacrificing the practicability of the barrel when in its assembled condition. Many efforts have been made to produce a sectional barrel which would occupy a small space when knocked down, and which at the same time when assembled produces a practical liquid barrel adapted to receive without injury the rough knocks and treatment that such barrels receive.

Although this demand has existed, so far as I am aware, such a sectional barrel has not heretofore been produced which would meet the conditions and requirements of such packages.

By my construction, which is the result of years of practical experience in the manufacture of metal barrels, I have in this three-piece structure produced a sectional knock-down barrel which is of a practical construction when assembled and will stand the rough usage and meet the other necessary requirements, while at the same time when disassembled the parts can be closely nested to occupy the least possible space for a practical structure and with all its parts united when disassembled so that they are all present and ready for use when the barrel is to be assembled.

While my barrel may be used for shipping all kinds of liquids, it is more particularly intended for the shipping of liquids that are used as foods, such, for instance, as the essential oils, and that are transported by water from foreign countries and returned empty, for instance in the case of olive and similar oils, that are so largely obtained from foreign lands.

Referring now to the drawings, my improved three-part knock-down barrel comprises a central portion 1, and two end portions 2 and 3. Each end of the central portion is provided with an annular laterally extending flange which has an approximately straight part 4, and a curved end 5, which forms a groove for the reception of a suitable packing ring 6.

The inner end of the end section 2 has a laterally extending flange of the same construction as the flanges of the part 1, in that the flange also has approximately a straight part 7 and a curved end 8, so that the curved ends 5 and 8 of the central and end sections 1 and 2 are adapted to receive a circular elastic packing 6, preferably of a good

quality of rubber. The other end section 3 has an annular laterally extending flange at its inner end of a similar shape in that it has a straight part 9 and a curved part 10.

When the center and end sections 1, 2 and 3 are in their assembled positions, the packing 6 is placed between the curved ends of the flanges as shown in Fig. 3, and a combined clamping ring and hoop 11 has at its inner edge an elongated tapered groove 12, adapted to embrace the ends of the flanges, as shown in Fig. 3. These combined hoops and clamping rings 11 are made into several sections preferably two or three, and their ends are united by a turn-buckle member 80 having at its center a nut 13, and at its opposite ends 14 and 15 right and left screw threads, so that when the turn-buckle is revolved by a suitable wrench on the nut 13, the ends of the combined ring and 85 rolling hoop 11 will be drawn together and toward the sections of the barrel, and will flex the curved ends of the flanges toward each other, as shown in Fig. 4, thus compressing the rubber packing 6 between them, 90 and making a liquid-tight joint.

Attention is directed to the fact that the straight parts 4, 7 and 9 of the flanges of the sections, preferably substantially rest on each other, as shown in Fig. 3, before the 95 clamping action takes place. By means of this construction when the curved ends of the flanges are flexed toward each other to compress the packing, the straight parts 4, 7 and 9 are held together under strong pressure so that the sections make a rigid structure by reason of the tight clamping of the straight parts of the flanges together. The grooves 12 in the combined hoops and 100 clamping rings 11 are so shaped that the 105 curved ends 5, 8 and 10 of the flanges when flexed, as shown in Fig. 4, approximately fit the groove, thus serving further to make a rigid structure when the sections are clamped as shown in Figs. 2 and 4.

Attention is directed to the fact that the end section 2 is larger than the end section 3, and that the end section 2 is smaller in diameter than the central section 1, the difference being preferably approximately the 115 thickness of the metal, so that when the section 2 is disassembled, it can be nested closely within the central section 1, as shown in Fig. 5. The end section 3 is smaller in diameter than the end section 2, the difference preferably being approximately the thickness of the metal so that the section 3 can be closely nested within the section 2, as shown in Fig. 5.

To accomplish this result, I make the 125 straight part of the flange 7 of the section 2 longer than the straight part 4 of the adjacent flange on the central section, and the straight part 9 of the flange of the end section 3 is wider than the straight part 7 of 130

- the end section 2. By this arrangement the end sections can be nested within each other and both nested within the central section, while at the same time when they are assembled, the curved parts of the end sections and the central section are opposite each other to receive the rubber or other suitable packing 6 between them. Although the foregoing result is accomplished by this 5 construction, in a full-sized barrel the difference in diameter between the end sections and the central sections will not be marked in appearance and not noticeable unless attention is directed to it.
- 10 By making the central and end sections of the varied relative diameters mentioned, I accomplish the close nesting of these parts which not only is economical in space for return shipment, but it causes the flanges to 15 abut against each other in their nesting positions at one end, and permits the flanges of the three sections to be sufficiently close to be embraced with the packing ring by the combined clamping ring and rolling hoop 20 25 30 35 40 45 50 55 60
- 11, which serves to protect the flanges, and at the other end the second combined clamping ring and rolling hoop embraces the flange at the other end of the central section and its packing ring.
- While I show the ends of the flanges of the three sections curved, I desire it to be understood that they could be angular so long as there is formed a space between the ends of the flanges to receive a packing, and when the ends are angular, the packing will be of a corresponding angular cross-section to fit in between the angular ends of the flanges.
- Also in a barrel of this construction, the bung 16 is placed in the central section 1, where it is protected and does not interfere with the nesting of the parts.
- While I have shown the packing ring 6 in the curved part of the flange of the section 3, when the parts are assembled as in Fig. 5, I desire it to be understood that this packing ring may be placed in the space 17, between the flange of the central section 1 and the lower wall of the inner end of the groove 12 of the hoop. In this instance, of course, the hoop will move inward and drop down in engagement with the straight part 9 of the flange of the section 3, thus increasing the space 17 from that shown in Fig. 5, sufficient to receive the packing ring with very little compression of it and will also contract the hoop so that it will not project beyond the hoop at the other end of the nested parts, as it does in Fig. 5.
- It will, of course, be understood that a three piece knock-down barrel of the type here described will take up considerably less shipping space than a two-piece barrel, and this difference will amount to a great deal 65 where there is a large number of these bar-

rels, as is the case particularly when shipping from foreign countries by water, for which the present invention is more particularly intended.

I do not limit myself to the exact construction here shown, as this may be slightly varied without departing from my invention so long as it comes within the spirit and scope of the appended claims.

For the purpose of preventing the barrel 75 from being opened and tampered with after it is assembled, a suitable seal is provided for the turn-buckle 13. In the form here shown, it consists in passing a wire 18 through the angular portion of the turn-buckle, and through one section of the hoop 11, as at 19, and having the ends of the wire fastened by a suitable seal 20. This will prevent the barrel being opened without breaking the seal.

Having thus described my invention, what I claim and desire to secure by Letters Patent is:

1. A three-piece knock down barrel, comprising a central section having laterally extending flanges at its ends, two end sections each having closed outer ends and annular laterally extending flanges at their inner open ends, all said flanges having their inner edges approximately straight and normally in engagement and their outer edges normally separated to receive a packing between them, and a clamping ring having an outwardly tapered groove in its inner side engaging the separated outer edges of the flanges for drawing them toward each other to hold the straight portions of the flanges firmly together and compress the packing between the outer separated edges of the flanges.

2. A three-piece knock down barrel, comprising central and end sections, each having annular laterally extending corresponding flanges at their adjacent ends to receive between them a packing, the inner edges of the flanges normally in engagement and the outer edges normally separated, said flanges capable of flexing toward each other, and a clamping ring having an annular groove in its inner side tapering outward to engage the outer separated flexing edges of the flanges for drawing them together for the purpose of firmly holding the inner edges of the flanges against each other to form a rigid structure and at the same time compress the packing between the separated outer edges of the flanges.

3. A three-piece shipping barrel comprising central and end sections having their adjacent ends provided with annular laterally extending flanges, the outer edges of the flanges being normally beyond a plane drawn between the inner edges of the flanges and transverse the pieces, whereby the inner edges of the flanges are normally in contact 130

and their outer edges separated, and a clamping ring having an outwardly tapered annular recess at its inner side, the wall of which engages the outer separated edges of the

5 flanges for the purpose described.

4. A three section barrel comprising a central section having at each end an annular laterally extending flange, two sections having closed outer ends and laterally extending

10 flanges at their inner ends coöoperating with the flanges of the central section, means for clamping the flanges toward each other, one end section having a smaller diameter than the central section to nest therein and

15 the other end section of smaller diameter than the first-mentioned section to nest therein, whereby a close nesting of the parts is accomplished.

5. A three section barrel, comprising a central section having at each end an annular laterally extending flange with their outer edges constructed to receive packings, two end sections having closed outer ends and annular laterally extending flanges at their 20 outer ends coöoperating with the flanges of the central section, the flanges on one end section being wider than the flanges of the

central section, and the flanges of the other end section being wider than the flanges of the first-mentioned end section, for the purpose described. 30

6. A three-section barrel, comprising a central section having at each end an annular laterally extending flange, two end sections each having closed outer ends and annular laterally extending flanges at their inner ends, one end section being smaller in diameter than the central section to nest therein in inverted position, and the other end section having a smaller diameter than the first-mentioned end section to nest therein in inverted position, the flange of the larger end section being wider than the flanges of the central section, and the flange of the smaller end section wider than the 40 flange of the larger end section, and all said flanges having their outer portions provided with an alined annular groove to receive a packing, and means for drawing the flanges together in assembled positions. 45

In testimony whereof I hereunto affix my signature. 50

GEORGE EUGENE MITTINGER.
