Invention Title:

Process for the production of organyloxy

end-terminated polysiloxanes

The following statement is a full description of this invention, including the best method of performing it known to me:

Process for the production of organyloxy end-terminated polysiloxanes

5 Triorganyloxysilyl or organodiorganyloxysilyl endterminated poly(diorganosilanes) cure into elastomeric
silicones in the presence of water, in particular
atmospheric humidity, and catalysts. They therefore form
the basic material for one-pack sealing and molding
10 compounds which crosslink at room temperature (RTC 1
Plastic Materials)

Di- or tri-organyloxysilyl-poly(diorganosiloxanes) are conventionally produced by the reaction of α,ω-dihydroxy-poly(diorganosiloxanes) with tetraorganyloxysilanes or triorganyloxysilanes in the presence of basic catalysts or catalyst systems.

Such catalysts or catalyst systems are:

20 amines (US-A 4,748,166 and US-A 4,395,526)
hydroxyl amine derivatives (EP-A-70 786)
ammonium carbamates (US-A 4,705,826)
mixtures of amines and carboxylic acids (EP-A 137 883).

25 The stated catalyst systems constitute compromises which exhibit a series of disadvantages. They require long reaction times and/or elevated temperatures. Substantial quantities of the catalyst are predominantly required which can then be removed from the reaction mixtures only with difficulty, so that undesired modifications of the product must be tolerated.

Acting against the, per se desirable, use of highly active alkali hydroxides, which are very efficient in respect of the stated conversion reaction (end termination) is the

Le A 28 980 - FC

fact that they bring about polymer rearrangements as an undesirable secondary reaction. These rearrangements can lead to chain scission and ultimately to branched polysiloxanes with an alkoxy group on each of the terminal silicon atoms. However, due to their low reactivity, such end groups are not suitable for the production of RTC 1 plastic materials.

It has thus already been suggested to neutralize the alkali
hydroxide catalyst on completion of the conversion reaction
by the subsequent addition of acids or acid-releasing
substances (EP-A 457 693, EP-A 468 239) in order to arrest
the undesirable secondary reaction in time. Such a manner
of proceeding does, however, set considerable demands,
particularly when reacting industrial quantities, which
demands may be met only with technical difficulty.

It has now been found that the undesirable secondary reaction may be suppressed or so far retarded, thus leaving sufficient time for neutralization of the alkali hydroxide catalyst, if substantially neutral alkali salts which are sufficiently soluble in the reaction medium are present during the end-termination reaction.

The object of the present invention is therefore a process for the production of triorganyloxysilyl or diorganyloxysilyl end-terminated poly(diorganosiloxanes) by the reaction of α,ω-dihydroxy(diorganosiloxanes) with tetraorganyloxysilanes or triorganyloxysilanes in the presence of alkali hydroxides, alkali alkoxides and/or alkali silanolates in catalytically active quantities, which process is characterized in that the reaction is performed in the presence of additionally at least one alkali salt which is soluble in the reaction system.

35

Le A 28 980

Ì

Suitable for the reaction are α, ω -dihydroxypoly(diorganosiloxanes) of general formula (I)

5

 $\begin{array}{c|c}
R^1 \\
\downarrow \\
O-Si \\
R^1
\end{array}$ OH $\begin{array}{c}
(I),\\
\end{array}$

10

15

wherein

R¹ designates a methyl, vinyl, phenyl or 3,3,3trifluoropropyl group, wherein different R¹ groups may be the same or different and

m designates such a number that corresponds to a polymer (I) viscosity between 0.01 and 1,000 Pa.s.

20

Suitable as organyloxysilanes are compounds of general formula (II)

$$R_{n}^{2} Si (OR^{3})_{4-n}$$
 (II),

25

wherein

R² designates an optionally substituted alkyl, alkenyl or aryl group with 1 to 10 C atoms

30

 \mathbb{R}^3

designates an optionally substituted aliphatic or cycloaliphatic hydrocarbon group with 1 to 6 C atoms and

35 n designates the number 0 or 1.

Le A 28 980

 ${\ensuremath{\mathsf{R}}}^2$ preferably stands for methyl or vinyl and ${\ensuremath{\mathsf{R}}}^3$ for methyl or ethyl.

The organyloxysilane is used in quantities of 1 to 20,
5 preferably 1 to 10, particularly preferably 1.5 to 6, moles
per OH-equivalent of polymer I. Mixtures of tri- and tetrafunctional organyloxysilanes may also be used.

According to the invention, as catalysts there are used alkali hydroxides of formula MeOH or alkali of formula ${
m MeOR}^4$, or alkali silanolates of formula ${
m MeO}({
m SiR}^5_2{
m O})_p{
m R}^5$ wherein

Me stands for Li, Na, K or Cs, preferably for Na or K,

R⁴ designates an optionally substituted linear or branched alkyl or cycloalkyl group with 1 to 10 C atoms,

20 R⁵ designates methyl,

p designates a number between 1 and 100, preferably 1 to 20, particularly preferably 1 to 5.

The catalyst is used in such quantities that between 0.5 and 1,000 ppm of alkali ions, related to polymer I, are present in the reaction mixture. Concentrations between 0.5 and 10 ppm are sufficient if the raw materials contain no acid constituents. In practice, concentrations between 20 and 200 ppm of alkali ions as catalysts are preferred.

The catalyst is preferably used with a little alcohol as a solvent. The same alcohol is preferably used as is formed in the conversion reaction. Methanol is, however,

Le A 28 980

Ť

particularly preferred because the risk of discoloration on storage of the catalyst system is small. The quantity of alcohol used as solvent is not critical. In general, quantities between 0.1 to 0.3 parts by weight, per 100 parts by weight of polymer I, are sufficient. Larger quantities of alcohol are not detrimental.

According to the invention, an alkali metal salt is used as an "anti-catalyst" to inhibit the undesirable secondary reaction. Salts of the alkali metals with the following are suitable:

an optionally substituted, linear, branched or cyclic alkyl carboxylic acid or a polycarboxylic acid with 0 to 30 C atoms, or

an optionally substituted aromatic carboxylic acid, or

a semi-ester of carbonic acid of general formula 20 $\mathbb{R}^6\text{-O}(\text{CO})\,\text{OMe}$, or

an aryl or alkyl sulphonic acid of formula R7-SO2-OMe, or

an aryl or alkyl phosphonic acid of formula R^8 -PO-(OMe)₂, wherein

 ${\bf R}^6$, ${\bf R}^7$ or ${\bf R}^8$ designate an aliphatic or aromatic, optionally substituted hydrocarbon group with 1 to 10 atoms and

Me designates the above-mentioned alkali metal ions, preferably Na or K.

The "anti-catalyst" is preferably used in quantities of at least 1 mole of anti-catalyst to 4 moles of catalyst. There

Le A 28 980

is no upper limit to the quantity of anti-catalyst in terms of the conversion reaction. Excessive quantities are, however, undesirable with regard to their remaining in the product. The quantity of anti-catalyst should preferably not exceed 4 moles per mole of catalyst. Particularly preferred is a molar ratio of anti-catalyst to catalyst of 2:1 to 1:2.

The activity of alkali ions in terms of the rearrangement
of polysiloxanes is not limited to the reaction here
described. The "anti-catalyst" according to the invention
is thus generally efficacious for the avoidance of
undesirable rearrangement reactions of polysiloxanes in the
presence of alkoxysilanes due to the presence of alkali
metal bases.

The catalyst system according to the invention consisting of catalyst and anti-catalyst can be added to the reaction mixture in any form. For example, the OH-functional polyorganosiloxane can first be mixed with the organyl-oxysilane, and then the anti-catalyst followed by the catalyst can be added. The anti-catalyst can also first be mixed with the OH-functional polydiorganosiloxane and the catalyst can be mixed separately with the organyl-oxysilane and then both reaction partners may be mixed together.

A premixed catalyst system is preferred consisting of catalyst, alcohol, anti-catalyst and part of the organyloxysilane provided for the reaction.

The alkali salts must be sufficiently soluble in the alcohol used or in a mixture of the alcohol and the organyloxysilane. The alkali metal of the salt can be different from the alkali metal of the base. The use of the

same metal is, however, preferred. Sodium or potassium are particularly preferred. Which of the two metals is used depends on the reactivity of the alkoxysilane (II). For sparingly reactive silanes, potassium or even caesium compounds are recommended. The use of sodium compounds is preferred for functionalization with reactive silanes, particularly methoxysilanes.

Suitable salts are, for example, salts of alkyl carboxylic acids, including formic acid. Salts of acetic acid or of 2-ethyl hexanoic acid are preferred. Salts of aromatic carboxylic acids, such as benzoic acid or methylbenzoic acid are also suitable. Salts of polycarboxylic acids are often less soluble than salts of monocarboxylic acids.

15 However, the use of semi-ester salts, for example of maleic acid, is favorable.

In practice, the use of semi-ester salts of carbonic acid can be of particular interest. Their formation from alkali alkoxides and carbon dioxide has been described (W. Behrendt, G. Gattow and M. Dräger, Zeitschrift für anorganische und allgemeine Chemie, 397 (1973), 237 to 246). These are water sensitive and thermally labile substances. Under room temperature conditions they are,

25 however, stable. On neutralization after functionalization they decompose forming carbon dioxide and leave no additional extraneous anions behind in the system. In order to produce such a catalyst solution, an alkali alkoxide solution in alcohol and optionally alkoxysilane is

30 conveniently divided into two halves, CO₂ is passed into one half until saturation and both solutions are combined.

Further suitable salts are alkali salts of alkyl- or arylsulphonic acids, preferably benzene or toluene sulphonic

acid. Salts of perfluoroalkane sulphonic acids may also be used.

Further suitable salts are alkali salts of phosphonic 5 acids, for example alkali salts of methylphosphonic acid or of phenylphosphonic acid.

The catalyst systems according to the invention may contain base and salt in molar ratios of between 4:1 and 1:4. A 10 ratio of between 2:1 and 1:2 is particularly preferred. Exact knowledge of the composition of the polymer (I) is, however, important for the selection of a ratio. All alkali or acid trace constituents of the polymer influence the necessary quantities and quantity ratios. Commercially 15 available polydimethylsiloxanes contain, for example, acid phosphates. Such phosphates, which to simplify can, for example, be described as KH,PO,, consume base, for example alkali alkoxide, from the catalyst system. This means that the quantity of alkali hydroxide or alkali alkoxide must be 20 correspondingly increased. A similar situation applies to acid constituents of the alkoxysilane, for example HCl residues arising from synthesis. The catalyst systems according to the invention have not only the advantage of suppressing undesirable polymer rearrangements, but are 25 also capable of compensating for variations in raw materials. In this manner, a constant course of the process is ensured even if there is a change in the concentrations of acid trace constituents in the raw materials used.

30 The alkoxysilane used is preferably the same compound that is to be functionalized with the polysiloxane (I).

Preparation of the catalyst system must be performed under dry protective gas. In particular, the uncontrolled ingress of carbon dioxide is to be avoided. It is particularly

Le A 28 980

Ì

advantageous to dissolve the solid alkali hydroxide in a mixture of alkoxysilane and alcohol and then carefully incorporate the free acid corresponding to the alkali salt.

- 5 Another method of preparation starts, for example, from a methanolic sodium methylate solution, to which is added the salt or the free acid. In this case, the addition of alkoxysilane may be dispensed with.
- 10 It is naturally also possible for the performance of functionalization to take the salt with the polymer and the alkoxysilane and optionally alcohol and incorporate the pure base solution. This manner of proceeding generally gives rise, however, to solubility problems and is more difficult to perform.

The catalyst systems according to the invention have the advantage that they rapidly catalyze the desired endtermination process. The end-termination reaction can therefore be performed at room temperature in a short time. The undesirable polymer rearrangement is, however, greatly inhibited in comparison with pure alkali hydroxides or alkali alkoxides. This inhibition facilitates control of the process of functionalization as a long period of time is available for neutralization of the basic catalyst and

is available for neutralization of the basic catalyst and the undesirable secondary reactions may to a great extent be avoided, even with very reactive alkoxysilanes. In particular, the process makes possible the production of RTC 1 plastic materials from OH functional polydimethyl-siloxanes in a single pot process.

The following examples are intended to illustrate the invention in more detail.

Unless otherwise stated, an OH terminated polydimethylsiloxane of viscosity 18 Pa.s was used for the experiments, which was produced with the assistance of acid activated bleaching earth. The polysiloxane produced in this manner was free of acid or alkaline trace constituents. The reactive group content was 0.006 mole SiOH per 100 g of polymer. The alkoxysilanes used contained less than 50 ppm of hydrolyzable chlorine.

<u>Le A 28 980</u>

Ì

Examples

Example 1

5 The following catalyst solutions were prepared:

Solution A:

0.6 g of solid sodium methylate were dissolved in 38 g of anhydrous methanol under dry argon and gaseous CO₂ was
10 introduced into the solution at 23°C until saturation. The CO₂ was first dried.

Solution B:

0.6 g of solid sodium methylate were dissolved in 38 g of anhydrous methanol.

Solution C (catalyst system):

10 g of solution A were combined with 10 g of solution B under dry argon.

20

25 g of methyltrimethoxysilane were added to 500 g of an OH terminated polydimethylsiloxane of viscosity 18 Pa.s under dry nitrogen. 0.84 g of solution C (catalyst system) were added at 23°C while the reaction mixture was stirred.

25

The viscosity profile of the mixture was determined over a period of approximately 60 minutes (Table 1).

Despite the high excess of alkoxysilane, the viscosity of the mixture did not change over a period of 10 minutes.

This means that no alteration to the polymer skeleton occurred.

The test was repeated and the following test for SiOH groups was performed after 10 minutes' reaction time:

100 parts by weight of the mixture to be tested were reacted with 5 parts by weight of a test solution. This solution was prepared by dissolving 20% dibutyltin oxide in tetraethoxysilane at 100°C with exclusion of atmospheric moisture. If a rapid increase in viscosity proceeding as far as gelation occurs after addition of the test solution, this is to be interpreted as an indication of incomplete saturation of the SiOH groups of the OH end-terminated polysiloxane.

10

No perceptible gelation occurred. The desired endtermination reaction had therefore occurred.

Comparative Example 1a

15

Example 1 was repeated with 0.42 g of solution B instead of solution C. The viscosity profile is to be found in table 1.

20 It can be seen from the viscosity profile that viscosity has perceptibly decreased after 10 minutes' reaction time. This means that the polymer skeleton had already been attacked by rearrangement reactions.

25 Comparative Example 1b

Example 1 was repeated with 0.42 g of solution A instead of solution C (Table 1). The viscosity did not change over the entire observation period of one hour. The test for SiOH groups after 10 minutes' reaction time was positive. This means that substantial quantities of SiOH were still present.

35
