(54) Title: ELECTRICAL PLUG HOUSING

(57) **Abrégé/Abstract:**

An electrical plug connector having fluid sealing between mated parts, and is provided with a locking mechanism. The mated parts consist of a male connector part having at least one contact pin extending therefrom, and a female connector part that contains at least one contact pin receptacle adapted to receive the male contact pins. The fluid sealing is accomplished by a bead extending circumferentially around the periphery of the female mating area, which fits into a groove provided on the periphery of the male part. The electrical plug locking mechanism includes a cylindrically shaped member extending from the periphery of the male part, and a latch attached to the periphery of the female connector part. This latch is adapted to receive the cylindrically shaped member therethrough, which locks the male and female connector parts together.

ABSTRACT OF THE DISCLOSURE

An electrical plug connector having fluid sealing between mated parts, and is provided with a locking mechanism. The mated parts consist of a male connector part having at least one contact pin extending therefrom, and a female connector part that contains at least one contact pin receptacle adapted to receive the male contact pins. The fluid sealing is accomplished by a bead extending circumferentially around the periphery of the female mating area, which fits into a groove provided on the periphery of the male part. The electrical plug locking mechanism includes a cylindrically shaped member extending from the periphery of the male part, and a latch attached to the periphery of the female connector part. This latch is adapted to receive the cylindrically shaped member therethrough, which locks the male and female connector parts together.

ELECTRICAL PLUG HOUSING

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to an electrical plug connector housing with fluid sealing and a locking mechanism.

2. The Prior Art

Connectors are known for coupling and uncoupling electrical cables. Connectors for outdoor applications frequently require a separate rubber or plastic gasket to obtain a moisture-proof seal. It would be advantageous to combine the gasket with the connector parts to reduce the number of parts and simplify the mating of the connector parts. The reduction of the number of parts makes it possible to produce the connector less expensively and makes mating easier.

SUMMARY OF THE INVENTION

The present invention provides an electrical plug connector having fluid sealing between mated parts, and is provided with a locking mechanism. The mated parts consist of a male connector part having at least one contact pin extending therefrom, and a female connector part that contains at least one contact pin receptacle adapted to receive the male contact pins. The fluid

sealing is accomplished by a bead extending circumferentially around the periphery of the female mating area, which fits into a groove provided on the periphery of the male part. The electrical plug locking mechanism includes a cylindrically shaped member extending from the periphery of the male part, and a latch attached to the periphery of the female connector part. This latch is adapted to receive the cylindrically shaped member therethrough, which locks the male and female connector parts together.

BRIEF DESCRIPTION OF THE DRAWINGS

Other objects and features of the present invention will become apparent from the following detailed description considered in connection with the accompanying drawings which discloses an embodiment of the present invention. It should be understood, however, that the drawings are designed for the purpose of illustration only and not as a definition of the limits of the invention.

In the drawings, wherein similar reference characters denote similar elements throughout the several views:

FIG. 1 shows a front view of the female connector part according to the invention;

FIG. 2 shows a front view of the male connector part;

FIG. 3 shows a side view of the female connector part with the other side being the same;

FIG. 4 shows a side view of the male connector part with the other side being the same;

FIG. 5 shows a cut-away view of the female connector part; and

FIG. 6 shows the female and male connector parts attached to each other.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to the drawings and, in particular, in FIG. 1 there is shown a female connector part 20 having contact receptacles 22 located within a molded housing 23 and electrically coupled to separate conductors of wire 21. Contact receptacles 22 are arranged to receive contact pins 12 of male connector part 10 (shown in FIG. 2).

Female connector part 20 further comprises a latch 70 on two opposite sides of housing 23. Latch 70 contains an aperture 72 into which cylindrical shaped flange 60 (shown in FIG. 2) fits to lock female connector part 20 and male connector part 10 together.

FIG. 2 shows a male connector part 10 which includes a molded

housing 13 and a rectangular body 14 from which contact pins 12 extend. Rectangular body 14 consists of four outer peripheral surfaces 15 which together form a male mating area. The male mating area has a height 17 which is 0.200 inches, for example.

Cylindrical shaped flanges 100 extend from two opposite sides of outer peripheral surface 15. Cylindrical shaped flange 100 has an hourglass shape and comprises a dome-shaped end 102. Cylindrical shaped flange 100 is preferably .225 mm in length, with .075 mm of this length being the dome-shaped end. Cylindrical shaped flange 100 contains an middle diameter 104, which is preferably .16 mm and an end diameter 106, which is preferably .187 mm. The diameter of aperture 72 is preferably .162 mm, which is larger than middle diameter 104 and smaller than end diameter 106 of cylindrical flange 100. Cylindrical shaped flange 100 is made of a resilient rubber so that it can be squeezed through latch 70 and then resume its initial shape to firmly lock the two connectors together. This flange is used to lock male connector part 10 to female connector part 20, as shown in FIG. 6.

Housing 13 has an overall height 30 and an overall width 31 which are 0.720 inches and 1.250 inches, respectively, for example. Rectangular body 14 includes corners 33 that have a 0.125 radius of curvature, for example.

As can be seen in FIGS. 1 and 3, female connector part 20 has

a height 40 and a width 41 that is approximately equal to height 30 and length 31 of male connector part 10. Female connector part 20 includes a lip 42 defining rectangular opening 24. Lip 42 has a width of 0.100 inches, for example. Lip 42 includes four interior facing corners 43 having a radius of curvature of 0.125 inches.

Rectangular opening 24 contains inner peripheral surfaces 25. The inner peripheral surfaces collectively define a female mating area. This female mating area has a depth 27, which is, for example, 0.200 inches, which is equal to height 17 of male connector part 10.

FIGS. 1-4 show the sealing mechanism of the electrical plug housing. A groove 50 is located between a first section 51 and a second section 52. Groove 50 has a width of 0.040 inches, for example. First section 51 has a width 54 of 0.115 inches and second section 52 has a width 55 of 0.045 inches, for example. Groove depth 56 is 0.020 inches, for example.

A bead 60 having a width of 0.030 inches, for example, is located between a first section 61 having a width of 0.050 inches, for example, and a second section 62 having a width of 0.120 inches, for example. The bead height is 0.020 inches, for example.

The female mating area is made of a resilient rubber or plastic material. Initially, first section 61 comes into contact

with second section 52. Thereafter, bead 60, which will fit snugly within groove 50, passes over second section 52. The female mating area expands slightly and when sections 61 and 62 come into overlapping relationship with sections 51 and 52, bead 60 snaps into groove 50 under the restoring force of the female mating area. The height of bead 60 and the depth of groove 50 are approximately equal, so that a water and vapor seal is achieved between contact pins 12, receptacles 22, and the external environment.

As can be seen in FIG. 5, there is a cut away view of female connector part 20 showing contact pin receptacles 22. Grounding pin receptacle 82 begins at inner peripheral surface 85 allowing grounding pin 80 to complete contact before contact pins 22. This provides a grounded connection before activation and remains grounded while the contact pins are being removed.

The small dimensions of connector parts 10 and 20 allow them to be used in a variety of applications where larger connectors could not fit. For example, in the spa industry, there is a need for a waterproof or splashproof connector that is small enough to be located in narrow passageways where larger conventional connectors cannot fit.

It should be noted that male connector part 10 and female connector part 20 can be equipped with a variety of configurations of contact pins and receptacles. For example, two or three contact

pins could be attached to male connector part 10. The negative or ground contact pin is generally a flat contact, with the hot contact pins having a generally circular cross section. A set of corresponding receptacles can then be provided on female connector part 20.

Accordingly, while only one embodiment of the present invention has been shown and described, it is obvious that many changes and modifications may be made thereunto without departing from the spirit and scope of the invention.

THE EMBODIMENTS OF THE INVENTION IN WHICH AN EXCLUSIVE
PROPERTY OR PRIVILEGE IS CLAIMED ARE DEFINED AS FOLLOWS:

1. A connector having a fluid sealing between mated parts
comprising:

a) a male connector part having a body containing at least
one contact pin, an outer rectangular peripheral surface of said
rectangular body forming a male mating area;

b) a female connector part containing at least one contact
pin receptacle having a rectangular opening adapted to receive said
male connector part within said opening, an inner rectangular
peripheral surface of said female connector part defining said
rectangular opening and forming a female mating area for said
contact pins;

c) a bead extending circumferentially around the rectangular
periphery of one of said male and female mating areas, the other of
said male and female mating areas having a groove extending
circumferentially around the rectangular periphery adapted to
receive said bead to create a fluid seal between said male and
female connectors;

d) at least one shaped member extending from the rectangular
periphery of said male connector part; and

e) at least one latch attached to the rectangular periphery of said female connector part, adapted to receive said at least one cylindrically shaped member therethrough, locking said male and female connector parts together.

2. The connector according to claim 1, wherein said male and female connector parts are movable along a mating axis to connect and disconnect said at least one contact pin and said at least one contact receptacle, said male and female mating areas being oriented parallel to the mating axis.

3. The connector according to claim 2, wherein said bead has a bead height measured transverse to said mating axis, and the groove has a groove depth which is approximately equal to said bead height.

4. The connector according to claim 3, wherein said bead has a bead width measured parallel to said mating axis, and said groove has a groove width which is slightly larger than said bead width.

5. The connector according to claim 4, wherein said male mating area has a male mating area length measured in a direction parallel to said mating axis, and said female mating area has a female mating area length which is approximately equal to said male mating area length.

6. The connector according to claim 5, wherein said male mating area has an end facing said at least one contact receptacle, said fluid seal is located substantially away from said end.

7. The connector according to claim 6, wherein said male mating area includes a first region located between said fluid seal and said end and a second region located on the opposite side of said fluid seal; said first region having a first region length measured in a direction parallel to said mating axis, and said second region has a second region length measured in a direction parallel to said mating axis that is less than half of said first region length.

8. The connector according to claim 7, wherein said bead width is approximately $1 \frac{1}{2}$ times the bead height.

9. The connector according to claim 8, wherein the first region length is approximately four times the bead width.

10. The connector according to claim 9, wherein said groove width is approximately twice the length of said groove depth.

11. The connector according to claim 1, wherein said cylindrically shaped member has a dome-shaped end.

12. The connector according to claim 11, wherein said cylindrically shaped member has an hourglass shape having a middle diameter and two end outer diameters.

13. The connector according to claim 12, wherein said latch contains an opening slightly larger than said middle diameter and slightly larger than said dome-shaped end.

14. The connector according to claim 13, wherein said cylindrically shaped member is made of a malleable material allowing said dome-shaped end to be pressed through said latch opening.

15. The connector according to claim 1, wherein said male connector part further comprises a grounding contact pin.

16. The connector according to claim 15, wherein said female connector part further comprises a grounding pin receptacle disposed at the peripheral surface of so that said grounding contact pin is connected before said at least one contact pin.
