UNITED STATES PATENT OFFICE.

GEORGE CORNELIUS TILYU, OF BROOKLYN, AND JEAN MARIE AUGUSTE LACOMME, OF NEW YORK, N. Y.

AQUATIC EXERCISING APPARATUS.

SPECIFICATION forming part of Letters Patent No. 567,056, dated September 1, 1896.

Application filed May 27, 1895. Serial No. 550,824. (No model.)

To all whom it may concern:

Be it known that we, GEORGE CORNELIUS TILYU, a citizen of the United States, residing at Brooklyn, in the county of Kings, and
5 JEAN MARIE AUGUSTE LACOMME, a citizen of the Republic of France, residing in New York city, in the county of New York, State of New York, have invented a new and Improved Aquatic Exercising Apparatus, of
10 which the following is a full, clear, and exact description.

The object of the invention is to provide a new and improved aquatic exercising apparatus for use at the seaside or other watering-
15 place or at a river-bank, and designed to permit persons of all ages and sexes to take sea or fresh water baths without risk, danger, or inconvenience, and to indulge with security in aquatic and hygienic exercises, such as
20 learning to swim, without a feeling of weariness or fatigue.

The invention consists principally of a column, a post extending a suitable distance above the water, a wheel mounted to turn on
25 the said column and supporting at its outer ends sheaves, and ropes or cables passing over the pulleys in the said sheaves and hanging downward.

The invention also consists of certain parts
30 and details and combinations of the same, as will be fully described hereinafter and then pointed out in the claims.

Reference is to be had to the accompanying drawings, forming a part of this specification,
35 in which similar characters of reference indicate corresponding parts in all the figures.

Figure 1 is a side elevation of the improvement with parts in section. Fig. 2 is a plan
40 view of the same. Fig. 3 is a cross-section of the exercising-boat, and Fig. 4 is a side elevation of the driving mechanism.

The improved aquatic exercising apparatus is provided with a column or post A, set in a
45 suitable foundation B, arranged in the bed of the ocean, river, or other watering-place where the apparatus is to be used. The column A is preferably of metal and extends a
50 suitable distance above the level of the water, as plainly illustrated in Fig. 1, and the said column is suitably supported by a tower or framework C, attached at its lower end to

piles C', connected with each other and driven in the ground in a circle around the foundation B.

On the upper end of the column A is mounted to turn horizontally a wheel D, provided
55 with a hub D', journaled on the column and resting on a suitable collar A', fastened to the column A. From the hub D' extend spokes D², the outer portions of which pass through
60 a rim D³, on the top of which is formed or secured a pulley D⁴, around which passes the cable E, extending from the wheel D to the shore or other place to connect with a driving
65 mechanism F for rotating the said wheel D by suitable power. The driving mechanism F is preferably provided with a pulley F', having any desired number of grooves for the
passage of the cable E, (see Fig. 4,) and this
70 pulley F' is secured on a shaft F³, journaled in suitable bearings in the frame F² of the driving mechanism.

On the shaft F³ are secured the fast and loose pulleys F⁴, connected by belt with suitable
75 machinery for imparting a rotary motion to the said shaft F³ to cause the pulley F' to impart a traveling motion to the cable E, so as to rotate the wheel D on the column A.

In order to give the desired friction to the cable E, so as to prevent the same from slipping,
80 and also to give the necessary resistance to the persons exercising upon the apparatus, as hereinafter more fully described, a second pulley F⁵ is provided, also containing grooves around which passes the cable E, as plainly
85 indicated in Fig. 4. This pulley F⁵ is attached to a shaft F⁶, journaled in bearings F⁷, fitted to slide in the frame F² and carried by screw-rods F⁷, held on the frame F², and engaged
90 at their outer ends by nuts in the shape of wheels F⁸, so that the operator on turning the latter can move the bearings F⁷ outward to tighten the cable passing over the pulleys
F' and F⁵ or to loosen the said cable by turning
95 the said wheels F⁸ in the inverse direction to move the bearings F⁷ inward.

The spokes D² project beyond the rim D³, previously mentioned, and each spoke carries at its outer end a keeper G, in which is pivoted
100 a sheave H, over the pulley of which passes a rope or cable I, extending downward with both runs, the lower ends of each cable

being provided with an eye I' and a hook I², adapted to be hooked into one of a series of loops I³, arranged on the other run carrying the eye I'. The lower ends of the cables I
 5 are adapted to support various apparatus for exercising, bathing, and other purposes, or for directly supporting persons taking hold of the eyes or rings I' to permit the persons to enjoy the water surrounding the column
 10 A. By making the cables adjustable by connecting the hooks I² higher or lower on the loops I³, provision is made for the rise and fall of the water, also for the use of different apparatus, &c.

15 As shown in Figs. 1 and 3, a bathing-boat J may be employed and supported from one of the cables I, the said bathing-boat being provided with ropes or chains J', attached to the eye I' of the cable and connected at its
 20 lower end to the front and rear ends of an inflated tube J², secured on apertured guide-rods J³, fitted to slide vertically in suitable guideways J⁴, arranged on the sides of the boat J, the latter being usually made in basket form of iron, willow-ware, or other material, or in the form of a closed boat, if desired. Pins J⁵ connect the guide-rods J³ with the guideways J⁴, so that the boat may be set
 25 higher or lower in the water, as desired, by the occupant of the boat.
 30

It will be seen that when the apparatus is in use the boat is carried around by the revolution of the wheel D, so that the occupant of the boat has a ride and at the same time is
 35 supported by the action of the water, thereby obtaining a bath and also fully benefiting by the action of the waves without any danger whatever.

A swimming-belt K of any approved construction and desirable material may be connected by a strap K' with one of the cables I, so that the bather can swim or learn how to swim without danger, it being understood that the person in the belt K is carried around
 40 by the rotation of the wheel D, and consequently receives a forward motion, thus aiding him considerably in learning the art of swimming. The apparatus thus employed

on the several cables I may be varied to facilitate various exercises in the water without any risk whatever to the person making use of the apparatus. 50

In order to strengthen the wheel D, braces D⁵ extend downwardly from the spokes D² and like braces D⁶ extend upwardly and inwardly from the said spokes, the sets of braces D⁵ and D⁶ being connected with sleeves D⁷ and D⁸, respectively, mounted to turn on the column A and supported on collars A² and A³, respectively, fastened to the column
 55 A. An additional set of braces D⁹ extend from the top face of the pulley D⁴ to the sleeve D⁸, as indicated in Fig. 1. The extreme upper end of the column A may carry a lamp of any approved construction. 65

In case a person in the belt or other apparatus hung on a cable desires he can raise himself out of the water for rest or other purposes by adjusting the cable, as before described. 70

Having thus fully described our invention, we claim as new and desire to secure by Letters Patent—

1. In an aquatic exercising apparatus, the combination of a vertically-sustained column, 75 a driven wheel carried on said column, a rope or cable suspended from the wheel, and a floating device carried by the rope or cable, the floating device consisting of an endless tubular float, a reticulated basket having 80 guides, and a perforated rod slidable in said guides and capable of adjustable connection with the basket, substantially as described.

2. A floating device for aquatic exercising apparatus, the device consisting of an endless 85 tubular float, a reticulated basket, perforated guide-rods to which the float is connected, and guides on the basket in which the guide-rods are respectively movable, substantially as described.

GEORGE CORNELIUS TILYOU.
 JEAN MARIE AUGUSTE LACOMME.
