The present invention relates to a single phase oral care composition comprising: a. a stannous salt b. a potassium salt c. a chelant d. monofluorophosphate (MFP). The composition of the invention has been found to allow prolonged contact between stannous ion and nitrate ion in a single dentifrice without toxic effects or insoluble products. The invention further provides for the maintenance of an efficacious fluoride ion level.
ORAL CARE COMPOSITIONS WHICH COMPRISE STANNOUS, POTASSIUM AND MONOFLUOROPHOSPHATE

FIELD OF THE INVENTION

The present invention relates to oral care compositions comprising both tin (II) and potassium ions as well as monofluorophosphate (MFP).

BACKGROUND OF THE INVENTION

Dentinal hypersensitivity is defined as acute, temporary, localised tooth pain in response to changes in temperature, pressure or chemistry. Exposure of the dentine, often due to recession of the gums, or loss of enamel, frequently leads to hypersensitivity. Dentinal tubules which are open to the surface correlate with hypersensitivity. Dentinal tubules lead from the pulp to the cementum. When the surface cementum of the tooth root is eroded, or exposed by periodontal disease, the tubules become exposed to the external environment and provide a pathway for the passage of fluid to the pulpal nerves.

"Nerve desensitising agents" can reduce the excitability of a nerve in a sensitive tooth by altering the chemical environment. It is known that potassium salts are effective in this way in the treatment of dentinal hypersensitivity. US3863006 discloses that potassium salts such as potassium nitrate, when incorporated in toothpastes, desensitise the teeth. It is believed that an elevated extracellular potassium concentration close to the pulpal nerves underlying sensitive dentin is responsible for the desensitising effect of oral care products which contain potassium salts.

An alternative way to treat hypersensitivity is to use an agent which partially or fully occludes the dentinal tubules. Tin (II) (stannous) ions, provided in oral compositions by stannous fluoride and/or other stannous salts, have long been valued for the multiple benefits that they can afford, including antimicrobial effects, control of breath malodour, control of dental plaque growth and metabolism, reduced gingivitis, decreased progression to periodontal disease, reduced coronal and root dental caries and erosion and reductions in dentinal hypersensitivity. Stannous salts are known to be efficacious in the reduction of dentinal hypersensitivity via this method as disclosed in US6592853 amongst others. Stannous is known in the art to occlude the dentin tubules and thus dramatically reduce fluid flow within the tubules which stimulate pain.
There are several disclosures of two component desensitising dentifrice in the prior art where the first component contains a potassium salt and the second component contains a stannous salt. The two components are generally maintained separately from each other until dispensed for application to teeth. Such compositions are disclosed in Colgate patents US5780015, US5693314, US5932192, US5843409, US6464963. The partial occlusion of the tubules by stannous ions is believed to increase the flux of potassium ions into the tooth as the inward diffuse flux is less dependent on the tubule radius than the outward fluid flow. It is disclosed in the art that attempts to include mixtures of desensitising agents such as stannous salts and potassium salts in a single desensitising dual composition have been found to be of limited effect as a means for delivering efficacious amounts of both ingredients to the teeth. US6464963 describes how insoluble stannic salts and stannous compounds are formed during storage. The present inventors overcome this problem via the addition of a chelant.

US5843409 discloses that prolonged contact between stannous ion and nitrate ion in a single dentifrice results in a reaction of these ions causing a conversion of nitrate into potentially toxic materials. It is believed from chemical first principles that the pre-cursor to any such products would be production of nitrites. Reducing agents such as stannous can convert nitrates into nitrites. Under acidic conditions the nitrite forms nitrous acid which is protonated and forms the nitrosonium cation. This can react with amines in the oral cavity to produce the toxic substance, nitrosamine. Careful stabilisation of the stannous via chelating agents can prevent this from happening. The present inventors have surprisingly found that there is no need for dual component toothpastes with dual containers to keep the stannous ion and potassium nitrate separate from each other. In aqueous models of nitrate and stannous containing dentifrices there were no signs of formation of nitrite over a wide pH range.

As described in EP1040819, sodium alkylsulphate surfactants, for example sodium lauryl sulphate (SLS), are generally not compatible with compounds that contain potassium because an insoluble potassium alkylsulphate precipitate forms when the sodium alkylsulphate is combined with a potassium salt. However, SLS in an oral care composition provides a high level of foam, which is desirable to the consumer. Although the combination of potassium and SLS is known to be unfavourable, many marketed products still use this formulation. This is generally managed by maintaining a low ionic strength within these formulations.
Fluoride ions are well known in the art to provide anti-caries benefits. Fluoride enhances remineralisation, acts anti-bacterially and strengthens enamel. It is desirable to treat sensitivity as well as caries in a single formulation. However, as US2008/0003187 acknowledges, it is difficult to maintain the effective properties of the fluoride ion in an oral care composition that also includes a sensitivity agent. In this instance the fluoride ions tend to precipitate out when effective amounts of potassium nitrate are added due to the low solubility of fluoride ion sources such as sodium fluoride and the resulting high ionic strength of the composition. US2008/0003187 solves this problem by providing a higher than usual quantity of water and hydrocolloid. This is not necessary in the present invention as the inventors have found using MFP as a fluoride source in an oral care composition which comprises both stannous and potassium ions, allows an efficacious level of fluoride ions to be maintained. MFP, commonly used in oral care compositions, does not provide free fluoride ions in water, in contrast with common fluoride sources such as sodium fluoride and stannous fluoride. MFP provides ions of monofluorophosphate (FPO$_3^{2-}$) when dissolved in water. This is broken down by enzymes (phosphatases) to provide free fluoride ions (F-) over time in-situ. The fluoride ions therefore do not precipitate in the oral care composition even when the composition is of a high ionic strength. The use of MFP further allows the use of SLS in a high ionic strength composition.

**SUMMARY OF THE INVENTION**

The present invention relates to a single phase oral care composition comprising:

a. a stannous salt
b. a potassium salt
c. a chelant
d. monofluorophosphate (MFP).

The composition of the invention has been found to allow prolonged contact between stannous ion and nitrate ion in a single phase dentifrice without toxic effects or insoluble products. The invention further provides for the maintenance of an efficacious fluoride ion level.

**DETAILED DESCRIPTION OF THE INVENTION**

Unless specified otherwise, all percentages and ratios herein are by weight of the total composition and all measurements are made at 25°C.
The present invention relates to a single phase oral care composition. The composition can be in the form of a mouth spray, mouthwash or a toothpaste or gel. Preferably the composition is in the form of a toothpaste or tooth gel suitable for use in brushing teeth.

The oral care compositions herein are single phase, by which is meant that all of the ingredients of the composition are containable within in a single compartment of a container and no further mixing is required before use.

Stannous ions

A first ingredient of the present oral care composition is a source of tin (II) (stannous) ions which preferably provides from 0.05% to 1.20% (500 to 12000 ppm) stannous ions, more preferably from 0.10% to 0.80% (1000 to 8000 ppm) stannous ions and even more preferably from 0.25% to 0.70% (2500 to 7000 ppm) stannous ions. Suitable stannous sources include stannous fluoride, stannous chloride, stannous acetate, stannous gluconate, stannous oxalate, stannous sulfate, stannous lactate and stannous tartrate. Especially preferred sources of tin (II) ions are stannous chloride, stannous fluoride, stannous gluconate and mixtures thereof due to their establishment as clinically proven salts to deliver stannous ions.

Potassium ions

A second ingredient of the present oral care composition is a source of potassium ions which preferably provides from 0.90% to 4.0% (9000 to 40000 ppm) potassium ions, more preferably from 1.50% to 3.60% (15000 to 36000 ppm) potassium ions and even more preferably from 1.90% to 2.50% (19000 to 25000 ppm) potassium ions. Suitable potassium sources include potassium nitrate, potassium gluconate, potassium citrate, potassium chloride, potassium tartrate, potassium bicarbonate, potassium oxalate, and mixtures thereof. Potassium nitrate, potassium gluconate, potassium citrate, potassium chloride and mixtures thereof are preferred due to their establishment as clinically proven salts to deliver potassium ions.

Chelants

The oral composition of the invention comprises one or more chelants, also known as chelating agents. The term "chelant", as used herein means a bi- or multidentate ligand having at least two groups capable of binding to stannous ions and preferably other divalent or polyvalent metal ions and which, at least as part of a chelant mixture, is capable of solubilising the stannous ions and other optional metal ions within the oral composition. Groups capable of binding to stannous
and other metal ions include carboxyl, hydroxyl and amine groups. Typically, those chelants useful herein will also form water soluble stable complexes with the stannous ions.

Suitable chelants herein include C₂ - C₆ dicarboxylic and tricarboxylic acids, such as succinic acid, malic acid, tartaric acid and citric acid; C₃ - C₆ monocarboxylic acids substituted with hydroxyl, such as gluconic acid; picolinic acid; amino acids such as glycine; phytic acid, salts thereof and mixtures thereof. The chelant can also be a polymer or copolymer in which the chelating ligands are on the same or adjacent monomer. Preferred chelant polymers are polyacids selected from the group consisting of a homopolymer of a monomer, a copolymer of two or more different monomers, and a combination thereof wherein the monomer or at least one of the two or more different monomers is selected from the group consisting of acrylic acid, methacrylic acid, itaconic acid, maleic acid, glutaric acid, aconitic acid, citraconic acid, mesaconic acid, fumaric acid and tiglic acid. Particularly preferred is a methylvinylether/maleic acid (PVM/MA) copolymer.

Also suitable as chelants are polyphosphates such as triplyphosphates. Longer chain linear polyphosphates, though good chelants, are susceptible to hydrolysis in aqueous compositions. Upon hydrolysis they form orthophosphates which form insoluble zinc complexes. They are therefore preferably used in anhydrous compositions.

Some materials, orthophosphate in particular, might be considered to be chelants in that they are bi- or multidentate ligands having at least two groups capable of binding to the divalent metal ions but nevertheless form insoluble zinc salts and are therefore not useful chelants for compositions which comprise zinc ions.

Phytate is a preferred chelant herein because it also provides stain removal benefits. However, because stannous phytate is partially soluble it is preferably not used as the sole chelant and is preferably used in combination with the organic acids described in this section. Preferred organic acid chelants herein comprise citrate, malate, tartrate, gluconate, succinate, lactate, malonate, maleate, and mixtures thereof, whether added in their free acid or salt forms.

The chelants in the composition will preferably be in range 0.1% to 10% of the composition to stabilize the stannous ions.

For chelants with a molecular weight of less than 1000, the molar ratio of the chelant(s) used to the stannous ion delivered from the stannous salt is preferably at least 0.70:1, more preferably at
least 0.8:1 and preferably 0.70:1 to 20:1. If other divalent metal ions, such as zinc, are added to the composition then the chelants should preferably be increased to a ratio of at least 0.70:1 of chelants to total metal ions. The molar ratio of chelants to divalent metal ions is the total number of moles of chelant(s) divided by the total number of moles of metal ions.

As a ratio of percentage weight of the chelant(s) to the stannous ion delivered from the stannous salt, particularly where one or more of the chelants has a molecular weight of greater than 1000, the composition will preferably have a ratio of chelant to stannous ion of at least 2:1, more preferably at least 5:1 and and preferably 2:1 to 10:1. If other divalent metal ions, such as zinc, are added to the composition then the chelants should preferably be increased to maintain a ratio of at least 2:1 of chelants to total metal ions.

Surfactant

The compositions of the present invention may include a surfactant. Useful surfactant types include anionic, amphoteric, nonionic and cationic surfactants.

Anionic surfactants can be included to provide cleaning and foaming properties, and are typically used in an amount from 0.1% to 2.5%, preferably from 0.3% to 2.5% and most preferably from 0.5% to 2.0% by weight. Anionic surfactants useful herein include the water-soluble salts of alkyl sulfates having from 10 to 18 carbon atoms in the alkyl radical and the water-soluble salts of sulfonated monoglycerides of fatty acids having from 10 to 18 carbon atoms. Sodium lauryl sulfate and sodium coconut monoglyceride sulfonates are examples of anionic surfactants of this type. Also useful herein are sarcosinate surfactants, alkyl sulfoacetates, isethionate surfactants and taurate surfactants, such as lauroyl sarcosinate, myristoyl sarcosinate, palmitoyl sarcosinate, stearoyl sarcosinate and oleoyl sarcosinate. All of the foregoing are generally used as their alkali metal or ammonium salts.

Cationic surfactants can also be used though care needs to be taken over their compatibility with other ingredients. They would typically be used at levels similar to those of the additional anionic surfactants. Cationic surfactants useful in the present invention include derivatives of aliphatic quaternary ammonium compounds having one long alkyl chain containing from 8 to 18 carbon atoms such as lauryl trimethylammonium chloride; cetyl pyridinium chloride; cetyl trimethylammonium bromide; di-isobutylphenoxyethyl-dimethylbenzylammonium chloride; cetly pyridinium fluoride; benzalkonium chloride; cetrimonium chloride; etc. Some of these cationic surfactants are also useful as anti-microbial agents. Some nonionic surfactants may be
useful at substantially higher levels, such as up to 20% if it is desired to use them to form a ringing gel. Examples of suitable nonionic surfactants include the poloxamers, polyethylene oxide condensates of alkyl phenols, long chain tertiary amine oxides, long chain tertiary phosphine oxides, long chain dialkyl sulfoxides, cocamide MEA, coamide DEA and mixtures of such materials.

Amphoteric surfactants which would typically be used in an amount from 0.1% to 2.5%, preferably from 0.3% to 2.5% and most preferably from 0.5% to 2.0% by weight. Useful surfactants include cocamidopropyl hydroxysultaine; sodium cocoamphoacetate; disodium cocoamphodiacetate; dodecyl betaine; cocoamidoethyl betaine; cocamidopropyl betaine; cocamidopropyl betaine; lauramidopropyl betaine; lauryl betaine and mixtures there of.

Fluoride ions

MFP in the present invention provides a source of fluoride ions. It is common to have a fluoride compound present in dentifrices and other oral compositions in an amount sufficient to give a fluoride ion concentration sufficient to provide anticaries effectiveness. The oral composition herein preferably comprises an MFP fluoride ion source sufficient to provide from 0.01% to 0.35% (100 to 3500 ppm) fluoride ions, preferably from 0.05% to 0.25% (500 to 2500 ppm) fluoride ions.

Zinc ions

Zinc ions may advantageously be included in oral compositions. Combining zinc ions with stannous ions can give a broader spectrum of anti-microbial activity. The present composition may include a source of zinc ions sufficient to provide from 0.1 to 1.5%, preferably from 0.1 to 1%, more preferably from 0.15 to 0.5% zinc ions by weight of the composition. Insoluble or sparingly soluble zinc compounds, such as zinc oxide or zinc carbonate, can be used as the zinc source. Preferred zinc sources however are soluble zinc sources such as zinc chloride or zinc sulphate. More preferred zinc sources are those where the zinc is already combined with a suitable chelating agent in the form of a salt or other complex, such as zinc citrate, zinc gluconate, zinc lactate and zinc glycinate. Especially preferred sources of zinc ions are zinc citrate, zinc gluconate, zinc lactate and mixtures thereof.

The preferred pH range of the present composition, to avoid the precipitation of stannous, is less than 7.5, preferably less than 7 and more preferably less than 6.5, such as from 4.5 to 7.5, more preferably 5 to 7 and even more preferably 5.5 to 6.5. The pH of the oral care composition is
preferably no lower than 4.5 for safety reasons. The pH of a dentifrice composition is measured from a 3:1 aqueous slurry of the dentifrice, i.e., 3 parts water to 1 part dentifrice.

Water

The term "orally acceptable carrier" as used means a liquid or semi-solid vehicle such as a paste or a gel for containing the active ingredients of the present invention and delivering them to the oral cavity. Water is commonly used as a carrier material in oral compositions. It is useful as a processing aid, is benign to the mouth and it assists in quick foaming of toothpastes. Water may be added as an ingredient in its own right or it may be present as a carrier in other common raw materials such as sorbitol and sodium lauryl sulphate. The term 'total water' as used herein means the total amount of water present in the composition, whether added separately or as a solvent or carrier for other raw materials but excluding that which may be present as water of crystallisation in certain inorganic salts. Preferred dentifrice compositions herein are aqueous compositions comprising from 20% to 65%, preferably from 30% to 55%, more preferably from 40% to 50% total water. The carrier can also include other conventional additives in oral care compositions such as desensitizing agents, teeth whitening agents such as peroxide sources, herbal agents, buffers, anti-staining agents, thickening materials, humectants, surfactants, a flavour system, sweetening agents, and colouring agents.

Other ingredients

The present oral care composition can comprise the usual and conventional ancillary components as more fully described hereinafter.

Dental abrasives are useful in oral compositions such as tooth pastes and gels for their ability to remove surface stain and pellicle and for polishing the teeth. A dental abrasive is a highly preferred ingredient of the present composition. Dental abrasives useful in the present oral composition of the subject invention include many different materials. The material selected must be one which is compatible with the composition of interest and does not excessively abrade dentin. Suitable abrasives include, for example, silicas including gels and precipitates, insoluble sodium polymetaphosphate, hydrated alumina, and resinous abrasive materials such as particulate condensation products of urea and formaldehyde. Another class of abrasives for use in the present compositions is particulate thermo-setting polymerized resins, as described in U.S. Pat. No. 3,070,510. Suitable resins include, for example, melamines, phenolics, ureas,
melamine-ureas, melamine-formaldehydes, urea-formaldehyde, melamine-urea-formaldehydes, cross-linked epoxides, and cross-linked polyesters.

Silica dental abrasives of various types are preferred herein because of their unique benefits of exceptional dental cleaning and polishing performance without unduly abrading tooth enamel or dentine. Silica abrasive polishing materials herein, as well as other abrasives, generally have an average particle size ranging from 0.1 to 30 μm, and preferably from 5 to 15 μm. The abrasive can be precipitated silica or silica gels such as the silica xerogels described in U.S. Patent Nos. 3,538,230 and 3,862,307. Examples include the silica xerogels marketed under the trade name "Syloid" by the W.R. Grace & Company, Davison Chemical Division and precipitated silica materials such as those marketed by the J. M. Huber Corporation under the trade name, Zeodent®, particularly the silicas carrying the designation Zeodent® 119, Zeodent® 118, Zeodent® 109 and Zeodent® 129. The types of silica dental abrasives useful in the toothpastes of the present invention are described in more detail in U.S. Patent Nos. 4,340,583, 5,603,920, 5,589,160, 5,658,553, 5,651,958 and 6,740,311.

Mixtures of abrasives can be used, such as mixtures of the various grades of Zeodent® silica abrasives listed above. The total amount of abrasive in dentifrice compositions of the present invention typically ranges from 6% to 50% by weight of the composition. Dental solution, mouth spray, mouthwash and non-abrasive gel compositions of the subject invention typically contain little or no abrasive.

An optional but preferred component of the compositions herein is a humectant. The humectant serves to keep the dentifrice from hardening upon exposure to air, to give a moist feel to the mouth, and, for particular humectants, to impart a desirable sweetness of flavour. The humectant, on a pure humectant basis, generally comprises from 5% to 70%, preferably from 15% to 45%, by weight of the composition. Suitable humectants include edible polyhydric alcohols such as glycerin, sorbitol, xylitol, butylene glycol, polyethylene glycol, and propylene glycol, especially sorbitol and glycerin.

In preparing tooth pastes or gels, it is often necessary to add a thickening agent or binder to provide a desirable consistency of the composition, to provide desirable active release characteristics upon use, to provide shelf stability, and to provide stability of the composition, etc. Thickening agents can include carboxyvinyl polymers, carrageenan, nonionic cellulose derivatives such as hydroxyethyl cellulose (HEC), and water soluble salts of cellulose derivatives.
such as sodium carboxymethylcellulose (NaCMC). Natural gums such as gum karaya, xanthan gum, gum arabic, and gum tragacanth can also be used herein. Suitable thickening agent levels can range from 0.1 to 5%, and higher if necessary.

Organic antimicrobial agents may also be employed. Included among such agents are water insoluble non-cationic antimicrobial agents such as halogenated diphenyl ethers, particularly triclosan and essential oils such as thymol. Water soluble antimicrobials include quaternary ammonium salts such as cetyl pyridinium chloride. Enzymes are another type of active that may be used in the present compositions. Useful enzymes include those that belong to the category of proteases, lytic enzymes, plaque matrix inhibitors and oxidases. The oxidases also have whitening/cleaning activity, in addition to anti-microbial properties. Such agents are disclosed in U.S. Patent Nos. 2,946,725, and 4,051,234.

Flavouring and sweetening agents are preferably also included in the present composition. Suitable flavouring agents and sweetening agents are well known in the art. Suitable flavour levels in the present oral compositions herein are from 0.1% to 5.0%, more preferably from 0.5% to 1.5%, by weight. Typically, a flavour oil will be manufactured in a separate step and will comprise multiple components, natural and/or synthetic in origin, in order to provide a balanced flavour which is acceptable to a broad range of people. Flavour components can be selected from mint, spice, fruit, citrus, herbal, medicinal, and common food flavour types (e.g. chocolate). Illustrative, but non-limiting examples of such components include hydrocarbons such as limonene, caryophyllene, myrcene, and humulene; alcohols such as menthol, linalool, 3-decanol, and pinocarveol; ketones such as piperitone, menthone, spicatone, and 1-carvone; aldehydes such as acetaldehyde, 3-hexanal, or n-octanal; oxides such as menthofuran, piperitone oxide, or carvyl acetate-7,7 oxide; acids such as acetic and oenoic; and sulphides such as dimethyl sulphide. Components also include esters such as menthyl acetate, benzyl isobutyrate, and 3-octyl acetate.

The flavour components may also include essential oils such as peppermint oils from e.g., Mentha piperita and Mentha arvensis; spearmint oils such as those from Mentha cardiaca and Mentha spicata; sage oil, parsley oil, marjoram oil, cassia oil, clove bud oil, cinnamon oil, orange oil, , lime oil, eucalyptus oil and anise oil. Other suitable components are cinnamic aldehyde, eugenol, ionone, anethole, eucalyptol, thymol, methyl salicylate, vanillin, ethyl vanillin, and vanilla extracts. Flavour components are described in more detail in Fenaroli's Handbook of Flavor Ingredients, Third Edition, Volumes 1 & 2, CRC Press, Inc. (1995), and Steffen
Arctander's Perfume and Flavour Chemicals, Volumes 1 & 2, (1969). A physiological cooling agent can also be incorporated into the flavour oil. The coolant can be any of a wide variety of materials. Included among such materials are carboxamides, menthol, acetics, ketals, diols, and mixtures thereof. Preferred coolants herein include the p-menthane carboxamide agents such as N-ethyl-p-menthane-3-carboxamide, (known commercially as "WS-3") and mixtures thereof and menthone glycerine acetal (known commercially as "MGA"). Further coolants suitable for the present invention are disclosed in WO 97/06695.

The compositions herein can further include herbal ingredients such as extracts of chamomile, oak bark, melissa, rosemary and salvia. These, and some of the herb-derived flavouring components mentioned above (such as thymol) can be included at levels just sufficient to provide a contribution to the flavour or they can be added at higher levels, such as 1% or more, in order to provide a greater therapeutic effect.

Sweetening agents which can be used include sucrose, glucose, saccharin, sucralose, dextrose, levulose, lactose, mannitol, sorbitol, fructose, maltose, xylitol, saccharin salts, thaumatin, aspartame, D-tryptophan, dihydrochalcones, acesulfame and cyclamate salts, especially sodium cyclamate, sucralose and sodium saccharin, and mixtures thereof. A composition preferably contains from 0.1% to 3% of these agents, more preferably from 0.1% to 1%.

The compositions may further include usual pigments, dyes and opacifiers, such as titanium dioxide. It will be appreciated that selected components for the compositions must be chemically and physically compatible with one another.

Examples

The following examples further describe and demonstrate toothpaste embodiments within the scope of the present invention. These examples are given solely for the purpose of illustration and are not to be construed as limitations of the present invention as many variations thereof are possible.

Toothpaste compositions according to the present invention are shown below with amounts of components in weight %. These compositions are made using conventional methods.

The dimensions and values disclosed herein are not to be understood as being strictly limited to the exact numerical values recited. Instead, unless otherwise specified, each such dimension is intended to mean both the recited value and a functionally equivalent range surrounding that value. For example, a dimension disclosed as "40 mm" is intended to mean "about 40 mm".
What is claimed is:

1. A single phase oral care composition comprising:
   a. a stannous salt
   b. a potassium salt
   c. a chelant
   d. monofluorophosphate (MFP).

2. A composition according to any Claim 1 which further comprises a surfactant selected from an anionic surfactant, a cationic surfactant, an amphoteric surfactant, an nonionic surfactant and mixtures thereof.

3. A composition according to any preceding claim which further comprises SLS.

4. A composition according to any preceding claim wherein the molar ratio of the chelant to the stannous ion delivered from the stannous salt is at least 0.70:1 and wherein the chelant has a molecular weight of less than 1000.

5. A composition according to Claim 1 wherein the percentage weight ratio of the chelant to the stannous ion delivered from the stannous salt is at least 2:1 and wherein the chelant has a molecular weight of greater than 1000.

6. A composition according to any preceding claim wherein the stannous salt is selected from stannous chloride, stannous fluoride, stannous gluconate and mixtures thereof.

7. A composition according to any preceding claim wherein the potassium salt is selected from potassium nitrate, potassium gluconate, potassium citrate and mixtures thereof.

8. A composition according to any preceding claim which further comprises a source of zinc ions.

9. A composition according to any preceding claim which further comprises a silica abrasive.
