J. B. MONROE.

ADJUSTABLE BUTTON FOR BOOT AND SHOE LASTS.

APPLICATION FILED SEPT. 25, 1907.
ADJUSTABLE BUTTON FOR BOOT AND SHOE LASTS.

No. 887,314.

To all whom it may concern:

Be it known that I, JAMES B. MONROE, a citizen of the United States, residing in the city and county of Denver, State of Colorado, have invented certain new and useful Improvements in Adjustable Buttons for Boot and Shoe Lasts, of which the following is a Specification.

The object of my invention is to provide improved means for adjusting the position of the projecting buttons used upon boot and shoe lasts, for the purpose of stretching the leather at the particular point desired. A device of this kind is illustrated in Patent No. 593,146, granted to John O. Stivers December 11, 1906.

In the drawings—Figure 1 is a top view of a last provided with an adjustable button. Fig. 2 is a side view of the same. Fig. 3 is a sectional view on the line 3 of Fig. 2, and Fig. 4 is a view of the several parts forming my improved button, the parts being ready for assemblage.

My improved adjustable button may be applied to any of the ordinary forms of boot and shoe lasts. The form illustrated is one in common use, and as the means for expanding the last in the shoe are old and well-known, a detailed description thereof is unnecessary for the purposes of this description.

The last illustrated consists of two sections, 1 and 2, hinged together at 3. As fully set forth in the specification of the Stivers patent above referred to, it is frequently desirable to stretch the leather at the particular part of the shoe where its pressure is felt, either owing to the existence of a corn or bunion upon the foot or other cause. In order to effect this purpose, it is necessary to provide an adjustable and removable projection upon the last, and my invention is concerned with the means for securing the button in its adjusted position. It is generally desired to secure extra stretching of the leather at some point along the side of the forward part of the shoe. There, therefore, illustrated the last as being provided with a groove 4 extending along the forward part thereof. Over the groove 4 is mounted a countersunk slotted plate 5, the inner edges of which project inwardly over the groove 4. The button 7 is provided with a shank 8, the shank being oblong in cross section and having its greater diameter coincide with the long diameter of the oblong button 7. The shorter diameter of the shank 8 is substantially equal to the width of the slot 9 in the plate 5, this construction being adopted for the purpose of permitting the shank to slide back and forth in the slot, but at the same time preventing it from rotating therein. By this means the long axis of the button is kept in alinement with the slot 9. The end of the slot 9 is enlarged—as shown at 10—for the purpose of permitting the entrance of the enlarged head 11 formed on the end of the shank 8. The head 11 being passed through the opening 10, the button may be slipped to any part of the slot 9, but cannot be withdrawn therefrom without being returned to the opening 10. Mounted upon the shank 8 is a washer 12 and a spiral spring 13, one end of the spring being seated against the inner side of the button 7 and the other end against the washer. By this arrangement the washer 12 is forced outward toward the head 11. The washer is preferably made somewhat larger than the opening 10. When the button is placed over the opening 10, therefore, the head 11 may freely pass through said opening, but the washer 12 is prevented from doing so. Upon applying pressure to the button, the spring 13 may be compressed until the head 11 has been depressed sufficiently to permit it to slide beneath the overhanging edges 6 of the plate 5. When the button is relieved of pressure, the spring 13 will cause the head 11 and washer 12 to firmly embrace the opposite surfaces of the plate 5, thus securely holding the button in its adjusted position.

While I have illustrated a specific embodiment of my invention, other structures embodying the same idea might be devised, and I therefore consider my invention as including broadly the structures set forth in the appended claims.

What I claim is:

1. A last provided with a groove, a projecting button having a part adapted to contact with the wall of said groove, and means for forcing said part against said wall and thus securing the button in position.

2. A last provided with a groove, a lip projecting over said groove, a button, a shank on said button, and fixed and movable projections on said shank, said projections engaging opposite faces of said lip.

3. A last provided with a groove, a lip projecting over said groove, a button, a shank
on said button, a fixed projection, and a
spring pressed projection on said shank
adapted to engage opposite faces of said lip.

4. A last provided with a groove, lips pro-
jecting from the sides of said groove, an oval
button, a shank on said button, said shank
being oblong in cross section, a head on the
end of said shank, a washer mounted on said
shank, and a spring tending to force said
washer toward said head.

5. A last provided with a groove, lips pro-
jecting from the sides of said groove, an oval
button having a headed shank, and a spring
pressed washer upon said shank, the head of
the shank and the washer engaging opposite
sides of said lips, and the shank being oblong
in cross section, whereby it is prevented
from rotating.

JAMES B. MONROE.
