ABSTRACT

The present invention concerns the use of a mixture of enantiomers enriched in the dextrogyral enantiomer of milnacipran and/or of at least one of its metabolites, as well as their pharmaceutically-acceptable salts, for the preparation of a drug intended to prevent or to treat disorders that can be managed by double inhibition of serotonin (5-HT) and norepinephrine (NE) reuptake, while limiting the risks of cardiovascular disturbances and/or organ and/or tissue toxicity.

FIG. 4
USE OF THE DEXTROGYRAL ENANTIOMER OF MILNACIPRAN FOR THE PREPARATION OF A DRUG

Matter enclosed in heavy brackets [ ] appears in the original patent but forms no part of this reissue specification; matter printed in italics indicates the additions made by reissue.

The present invention concerns the use of a mixture of enantiomers enriched in the dextrogyral enantiomer of milnacipran and/or of at least one of its metabolites, as well as their pharmaceutically-acceptable salts, for the preparation of a drug intended to prevent or to treat disorders that can be managed by double inhibition of serotonin (5-HT) and norepinephrine (NE) reuptake, while limiting the risks of cardiovascular disturbances and/or of organ and/or tissue toxicity. More specifically, the mixture of enantiomers in accordance with the invention is intended to treat depression, chronic fatigue syndrome and urinary incontinence.

Milnacipran (Z(+)-2-(amino methyl)-N,N-diethyl-1-phenyl cyclopropane carboxamide), a molecule synthesised at the PIERRE FABRE MEDICAMENT Research Centre (Castres, France), also called TN-912, dalcipran, minacipran, midalipran or midalipran is known to be a dual inhibitor of serotonin (5-HT) and norepinephrine (NE) reuptake. Milnacipran and its method of preparation are described in U.S. Pat. No. 4,478,836. Other information relating to milnacipran can be found in the twelfth edition of the Merck Index, as entry no. 6 281.

Dual inhibitors of serotonin (5-HT) and norepinephrine (NE) reuptake correspond to a well-known class of antidepressant agents which selectively inhibit reuptake of both serotonin and norepinephrine. By way of example, venlafaxine and duloxetine are also dual inhibitors of serotonin and norepinephrine. Studies have shown that the ratio of norepinephrine reuptake inhibition to serotonin reuptake inhibition by milnacipran is approximately 2:1 (Moret et al., 1985 Neuropharmacology 24(12): 1211-1219; Palmier et al., 1989, Eur J Clin Pharmacol 37: 235-238).

U.S. Pat. No. 4,478,836 describes the use of milnacipran for the treatment of disorders of the central nervous system, in particular depression. Patent application 6004/26623 describes the use of milnacipran in association with phenylalanine and tyrosine in indications such as the treatment of fatigue, syndromes associated with pain, chronic fatigue syndrome, fibromyalgia, and irritable bowel syndrome. Patent application 62235 describes a composition containing milnacipran in association with one or several antimusscarinic agents in large number of indications including including depression. Application 6004/26623 describes a pharmaceutical composition containing milnacipran and idaxozon as an associated product for use simultaneously, separately or staggered in time to treat depression and its various forms, as well as disorders in which antidepressants are used. Milnacipran is also indicated for use in the treatment of urinary incontinence (FR 2 759 290).

Milnacipran exists in the form of two optically active enantiomers: the dextrogyral enantiomer or Z-(1S,2R)-2-(amino methyl)-N,N-diethyl-1-phenyl cyclopropane carboxamide and the levogyral enantiomer Z-(1R,2S)-2-(amino methyl)-N,N-diethyl-1-phenyl cyclopropane carboxamide. In its hydrochloride form, milnacipran (also called F2207) is currently marketed (IXEL, PIERRE FABRE MEDICAMENT, France) in the form of a racemic mixture as a serotoninergic and norepinephrine antidepression agent. F2695 and F2696 designate the dextrogyral and levogyral enantiomers respectively of milnacipran hydrochloride (F2207):

The inventors have now performed a pharmokinetic study in man on the racemate and on the two enantiomers of milnacipran which uses enantiomer-selective assay methods. They have thus demonstrated the absence of racemisation of the enantiomers in vivo.

Furthermore, although the racemate has been resolved, no analysis of the pharmacological and toxicological properties of the two enantiomers has been performed using modern, currently-available methods such as cardiovascular measurements by telemetry, or genomic analyses for predictive pharmacototoxicology in vitro.

As with any active substance, antidepressants can induce adverse events or certain toxic effects that essentially derive from the pharmacological properties of these drugs, as well as from the dosage, from individual variations in patients (genetic polymorphism, organ-function insufficiency, sex, age) or from drug interactions. Antidepressants are thus the third most common class of products responsible for intoxication, after hypnotics and tranquillisers (Nore et al., 1987 Thérapie 42: 555-558). The risk of overdose with antidepressants is serious, since it can lead to death. Among the causes of acute intoxication with antidepressants should be mentioned accidental ingestion by children (all the more so since certain antidepressants are used in the treatment of enuresis), suicide attempts, accidental overdosage by physicians, concomitant medications in elderly patients, age-related physiological and pharmacokinetic changes (cardiac insufficiency, hepatic and/or renal insufficiency . . .) and slowing down of metabolism whether genetic in origin or drug-induced (enzyme inhibition). After children, the elderly therefore represent the second at-risk population among patients treated. Elderly persons have higher plasma concentrations, related to reduced renal and/or hepatic clearance, and the risks of intoxication are more serious (Mea der-Woodruff et al., 1988 J. Clin. Psychopharmacol. 8: 28-32).

The adverse side-effects, generally benign, which have been observed during treatment with milnacipran usually occur within the first or the first two weeks of treatment and diminish thereafter, in parallel with improvement in the depressive episode. The most commonly-reported adverse events in single-drug therapy or in association with other psychotropics are dizziness, hypersudation, anxiety, hot flushes and dysuria. Certain less commonly-reported adverse events are nausea, vomiting, dry mouth, constipation, tremor,
palpitations, agitation, and cutaneous eruptions. Moreover, it is known that in patients with a history of cardiovascular disease or who concomitantly receive treatment for a cardiac condition, milnacipran can increase the incidence of cardiovascular adverse events (hypertension, hypotension, orthostatic hypotension, palpitations). In patients with high blood pressure or having heart disease, it is therefore recommended to increase medical supervision since milnacipran in the form of a racemic mixture is likely to increase the heart rate. In those rare cases of overdose observed with milnacipran (at doses from 800 mg to 1 g) in single-therapy, the main symptoms observed are vomiting, respiratory disturbances and tachycardia (The Vidal Dictionary, 78th Edition, 2002). Another adverse event occasionally induced by milnacipran is elevated transaminase levels which may reflect a certain hepatic toxicity.

The allergic reactions that could potentially develop a certain number of adverse clinical manifestations during or following treatment with milnacipran are children, the elderly, patients with hepatic and/or renal insufficiency, patients receiving treatment that induces organ and/or tissue toxicity, in particular hepatic or renal toxicity, patients receiving treatment for a heart condition or that induces cardiovascular side-effects, patients with a history of cardiovascular disease and/or having cardiovascular disorders, especially those with disorders of cardiac rhythm, of blood pressure (hypertensive patients) and patients suffering from heart disease.

Concerned to prevent, to an ever-greater extent, the occurrence of possible side-effects that could constitute a danger, however small, to the health of patients treated with milnacipran, the inventors have now discovered that, surprisingly and unexpectedly, the dextrogynral enantiomer of milnacipran, which is essentially responsible for the selective inhibitory activity on serotonin and norepinephrine reuptake, induces fewer side-effects of a cardiovascular nature and less organ and/or tissue toxicity, especially hepatic, than the racemic mixture. In particular, the inventors have discovered that, in dogs, administration of the dextrogynral enantiomer of milnacipran leads to a lesser increase in heart rate and blood pressure, particularly diastolic blood pressure, than that which can be induced by administration of the racemic mixture. Moreover, the inventors have discovered that the dextrogynral enantiomer of milnacipran (F2695) has a better profile of genomic toxicity than the levogynral enantiomer of milnacipran (F2696) in an experimental model using primary rat hepatocytes. The inventors have also demonstrated that the levogynral enantiomer of milnacipran (F2696) has a profile of genomic toxicity similar to that obtained with clozapine, which is used as a reference psychotropic product known for its relative hepatic toxicity.

The object of the present invention is thus use of a mixture of enantiomers of milnacipran enriched in the dextrogynral enantiomer, preferentially the substantially-pure F2695 enantiomer, as well as with their pharmaceuticallyacceptable salts, for the preparation of a drug intended to prevent or to treat disorders or conditions that can be managed by double inhibition of serotonin (5-HT) and norepinephrine (NE) reuptake, while limiting the risks of cardiovascular disturbances and/or while limiting the risks of organ and/or tissue toxicity.

The term “cardiovascular disturbances” is understood to refer to adverse cardiovascular side-effects of the drug administered alone or in association with other active substances. For the purposes of the present invention, the term “side-effect” is understood to mean the foreseeable activity of a drug in an area other than that for which it is administered, that may be bothersome or undesirable when it limits the use of the drug.

The term “toxicity” is understood to mean the property of a drug to induce harmful effects on organs or tissue, in particular organs or tissues involved in the metabolism of milnacipran, especially hepatic and/or renal metabolism of milnacipran, and more specifically during the first pass of milnacipran in the liver. Preferentially, organ toxicity is cardiac toxicity and the said tissue toxicity is hepatic and/or renal toxicity.

For the purposes of the present invention, the phrases “while limiting the risks of cardiovascular disturbances” or “while limiting the risks of toxicity” is understood to mean the fact of preventing these risks from increasing significantly in a patient following administration of the drug.

For the purposes of the present invention, the term “dextrogynral enantiomer of milnacipran” designates the dextrogynral enantiomer of milnacipran, as well as its pharmaceuticallyacceptable salts. Preferentially, this is the dextrogynral enantiomer of milnacipran hydrochloride (F2695). “Levogynral enantiomer of milnacipran” designates the levogynral enantiomer of milnacipran, as well as its pharmaceuticallyacceptable salts (F2696). “Racemic mixture” designates a 50:50 mixture by weight of the dextrogynral enantiomer of milnacipran and the levogynral enantiomer of milnacipran, as well as their pharmaceuticallyacceptable salts.

For the purposes of the present invention, “mixture of the enantiomers of milnacipran enriched in the dextrogynral enantiomer” signifies a mixture of the dextrogynral enantiomer and the levogynral enantiomer of milnacipran in which the mass/mass ratio of the dextrogynral enantiomer to the levogynral enantiomer is greater than 1:1. In the mixture of the enantiomers of milnacipran enriched in the dextrogynral enantiomer, the mass/mass ratio of the dextrogynral enantiomer to the levogynral enantiomer is advantageously greater or equal to 55:45, more advantageous when greater than 60:40, yet more advantageous when greater than 65:35, yet more advantageous when greater than 70:30, yet more advantageous when greater than 75:25, yet more advantageous when greater than 80:20. Produced in a particularly advantageous mode, the mass/mass ratio of the dextrogynral enantiomer to the levogynral enantiomer is greater than 82:18, in a more advantageous manner greater than 84:16, in an even more advantageous manner greater than 86:14, in an even more advantageous manner greater than 88:12, in an even more advantageous manner greater than 90:10. Produced in a preferred mode, the mass/mass ratio of the dextrogynral enantiomer to the levogynral enantiomer is greater than 91:9, in a more preferred manner greater than 92:8, in an even more preferred manner greater than 93:7, in an even more preferred manner greater than 94:6, in an even more preferred manner greater than 95:5, in an even more preferred manner greater than 96:4, in an even more preferred manner greater than 97:3, in an even more preferred manner greater than 98:2, in an even more preferred manner greater than 99:1, in an even more preferred manner greater than 99.5:0.5. In a particularly preferred manner, the mixture of enantiomers of milnacipran enriched in the dextrogynral enantiomer is substantially pure, that is to say, containing approximately 100% dextrogynral enantiomers by weight.

The use of metabolites also enters into the scope of the present invention, preferentially the metabolites of milnacipran that are active in vivo, in their Z or E form, and their pharmaceuticallyacceptable salts, such as:
5 the hydrochloride of Z-phenyl-1 aminomethyl-2 cyclopropane carboxylic acid (F1567):

Molecular mass: 277.7
Characteristics: white crystals
Melting point: 220° C.
Plate chromatography:

- Medium: silica
- Solvent: Butanol/Ethanol/water (6/2/2)
- Developer: Ultraviolet and ninhydrine
- \( R_f \) = 0.6

---

6 the oxalate acid of Z-phenyl-1-ethylamino carbonyl-1 aminomethyl-2 cyclopropane (F2800):

Molecular mass: 308.33
Characteristics: white crystals
Melting point: 150° C.
Plate chromatography:

- Medium: silica
- Solvent: CHCl3/methanol/NH4OH (90/9/1)
- Developer: Ultraviolet and ninhydrine
- \( R_f \) = 0.4

---

7 the hydrochloride of Z-phenyl-1 aminocarbonyl-1 aminomethyl-2 cyclopropane (F2941):

Molecular mass: 226.74
Characteristics: white crystals
Melting point: 245° C.
Plate chromatography:

- Medium: silica
- Solvent: CHCl3/methanol/NH4OH (80/18/2)
- Developer: Ultraviolet and ninhydrine
- \( R_f \) = 0.30

---

These metabolites have, just as milnacipran has, a chiral centre which confers optical isomerism on these metabolites that exist in the form of dextrorotary and levorotary enantiomers. The racemic ratio of the two enantiomers of the milnacipran metabolite in the mixture of enantiomers is as previously described for the enantiomers of Milnacipran.

The present invention covers therefore these active metabolites, as well as their pharmaceutically-acceptable salts, in addition to their use as a drug in the treatment of the disorders described in the present patent such as depression, pain, fibromyalgia and urinary incontinence. The metabolites in accordance with the invention are in the form of racemates or preferentially in the form of a mixture of enantiomers enriched in the most active enantiomer. In a preferable manner, the active metabolite used comes from the F2695 enantiomer and is the dextrogastral enantiomer of the active metabolite. In a more preferable manner, this is the dextrogastral enantiomer of the hydrochloride of Z-(para-hydroxyphenyl)-1 diethylaminocarbonyl-1 aminomethyl-2 cyclopropane (F2782). The term “active metabolite” is understood to designate a derivative of milnacipran metabolised in vitro or in vivo and having the capacity to inhibit reuptake of serotonin and of norepinephrine; preferentially, these are F2782, F2941, F2800, F1612 and F1567. For the purposes of the present invention, the active metabolites in vivo described
and claimed for in the present invention include all the enantiomers, the isomers or the tautomers when the component is capable of being present in the form of an enantiomer, an isomer or a tautomer.

The object of the present invention is therefore the use of a mixture of enantiomers preferentially enriched in the dextrogyral enantiomer of at least one metabolite of Milnacipran, preferentially chosen among F2782, F2941, F2800, F1612 and F1567, as well as their pharmaceutically-acceptable salts, for the preparation of a drug intended to prevent or to treat disorders or conditions that can be managed by double inhibition of reuptake of serotonin (5-HT) and of norepinephrine (NE), while limiting the risks of cardiovascular disturbances and/or while limiting organ and/or tissue toxicity, in particular, cardiac, hepatic and/or renal toxicity.

The use of a mixture of enantiomers of milnacipran enriched in the dextrogyral enantiomer, preferably the substantially-pure F2695 enantiomer, and at least one of its active metabolites, preferentially chosen among F2782, F2941, F2800, F1612 and F1567, preferentially enriched in the dextrogyral enantiomer, for the preparation of a drug intended to prevent or to treat disorders or conditions that can be managed by double inhibition of reuptake of serotonin (5-HT) and of norepinephrine (NE), while limiting the risks of cardiovascular disturbances and/or while limiting organ and/or tissue toxicity, in particular, cardiac, hepatic and/or renal toxicity also enters into the scope of the present invention.

"Pharmaceutically-acceptable salts" designates all salts that retain the efficacy and properties of an active substance and that do not cause side-effects. Such salts may be prepared starting from acids or bases, organic or mineral. Preferentially, these are pharmaceutically-acceptable salts of mineral or organic acids. By way of example, but not limited to these, halogen hydrates such as the hydrochloride and the bromohydrate, the fumarate, the maleate, the oxalate, the citrate, the methane sulphonate, the glutamate, the tartrate, the mesylate and their possible hydrates should be mentioned.

For the purposes of the present invention, the term "mixture of enantiomers" signifies the mixture of enantiomers of milnacipran enriched in the dextrogyral enantiomer, as well as their pharmaceutically-acceptable salts, and/or the mixture of enantiomers of at least one of the metabolites of milnacipran, preferentially enriched in the dextrogyral enantiomer, as well as their pharmaceutically-acceptable salts.

The mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, is administered to all types of patients requiring such treatment, whether it be for therapeutic and/or prophylactic purposes. For therapeutic purposes, the aim is to eradicate or to improve the condition to be treated and/or one or more related symptoms. For prophylactic purposes, the aim is to prevent the appearance of the condition to be treated and/or one or more related symptoms. Nevertheless, the mixture of enantiomers in accordance with the invention is particularly adapted to populations of at-risk patients who may be likely to develop certain adverse clinical manifestations during or following treatment with milnacipran in the racemic form. These are principally children, the elderly, patients with hepatic and/or renal insufficiency, patients receiving treatment that induces hepatic or renal organ and/or tissue toxicity, patients receiving treatment for a heart condition, patients receiving treatment that induces cardiovascular side-effects, patients with a history of cardiovascular disease (for example, myocardial infarction) and/or having cardiovascular disorders, such as patients with cardiac rhythm disorders (tachycardia, bradycardia, palpitations), patients with blood pressure disorders (hypotensive or hypertensive patients) or patients suffering from heart disease.

Among the numerous disorders or conditions that have as symptoms cardiac rhythm disorders and for which the present invention is particularly well-adapted in the treatment of at-risk patients who suffer from them, tachycardia which corresponds to an acceleration of the rhythm of the heart beat (tachycardia is moderate when the heart rate is from 80 to 100 beats per minute, severe when it exceeds 100), palpitations, extrasystoles (asloratic, frequent or during myocardial infarctus), auricular fibrillation, flutter and auricular tachysystole, bradycardia, cardiac insufficiency, and myocardial infarctus should be mentioned.

Among the numerous disorders or conditions that have as symptoms blood pressure disorders and for which the present invention is particularly well-adapted in the treatment of at-risk patients who suffer from them, arterial hypertension, malignant arterial hypertension, pulmonary arterial hypertension, portal hypertension, paroxysmal essential hypertension, hypotension, orthostatic hypotension and intra-cranial hypertension should be mentioned.

Advantageously, those cardiovascular disorders for which the risks can be limited by the administration of the mixture of enantiomers in accordance with the invention, and preferentially by the administration of the substantially-pure F2695 enantiomer, are as follows:

- elevated diastolic and/or systolic blood pressure measured in millimeters of mercury (mmHg); more specifically, this is an increase in diastolic blood pressure, and/or,
- cardiac rhythm disorders, in particular, an increase in the patient's heart rate.

Systolic blood pressure is the maximal value for blood pressure, and it corresponds to the moment when the first heart sound is heard in the humeral artery during measurement of blood pressure. The systole is the interval of the cardiac cycle during which the heart cavities contract, causing expulsion of the blood. Diastolic blood pressure is the minimal value of blood pressure, corresponding to the disappearance of sound waves in the humeral artery when the cuff of the sphygmomanometer is deflated during measurement of blood pressure. The diastole is the interval of the cardiac cycle during which the heart cavities fill with blood. Elevation of systolic and or diastolic pressure means increased blood pressure which is characteristic of systemic arterial hypertension (and its variant forms), the symptoms of which may be the following: headache, fatigue, mild sensorial disturbances such as dizziness, buzzing in the ears, palpitations, nosebleeds, confusion or drowsiness, cramps, numbness or tingling in the feet and hands. Systemic arterial hypertension (and its variant forms) can lead to serious, indeed fatal, complications: cerebral vascular accidents, left ventricular heart failure, kidney failure, ischemic heart diseases (myocardial infarctus, angor and their variant forms). According to current guidelines, a patient is considered to have arterial hypertension when his/her diastolic blood pressure is above 90 mmHg and his/her systolic blood pressure is above 140 mmHg.

The toxicity for which the risks can be limited by the administration of the mixture of enantiomers in accordance with the invention is advantageously organ toxicity, particularly cardiac toxicity, and/or tissue toxicity, in particular hepatic and/or renal toxicity. Tissue toxicity may be revealed by the presence of icterus or by laboratory markers.

The use of the mixture of enantiomers in accordance with the invention in veterinary medicine for the treatment of
animals, in particular household pets or breeding animals that require such treatment also enters into the scope of the present invention.

Because of their pharmacological properties, in particular as dual inhibitors of serotonin (5-HT) and norepinephrine (NE) reuptake, the mixture of enantiomers is especially useful in the preparation of drugs intended for preventive and/or curative treatment of a number of disorders and conditions (syndromes) described hereinafter, while limiting the risks of cardiovascular disturbances and/or while limiting organ and/or tissue toxicity, in particular cardiac, hepatic and/or renal toxicity.

Among these disorders or conditions, disorders of the central nervous system as defined in <<The Diagnostic and Statistical Manual of Mental Disorders—IV (DSM-IV), 1995 American Psychiatric Association>> should be mentioned. By way of example, but not limited to these, the following disorders and conditions should be mentioned: depression, in particular deep depression, resistant depression, depression in the elderly, psychotic depression, depression induced by treatment with interferon, depressive state, manic-depressive syndrome, seasonal depressive episodes, depressive episodes related to general health status, depressive episodes related to mood-altering substances, bipolar disease, schizophrenia, generalised anxiety, morose and masaric states, stress-related diseases, panic attacks, phobias, in particular agoraphobia, obsessive-compulsive disorders, behavioural disorders, oppositional disorders, post-traumatic stress disorder, depression of the immune system, fatigue and accompanying pain syndromes, chronic fatigue syndrome, fibromyalgia, and other functional somatic disorders, autism, disorders characterised by attention deficit due to general health status, attention disorder due to hyperactivity, eating disorders, neurotic bulimia, neurotic anorexia, obesity, psychotic disorders, apathy, migraine, pain and in particular chronic pain, irritable bowel syndrome, cardiovascular diseases and in particular anxiety-depressive syndrome in myocardial infarctus or in hypertension, neuro-degenerative diseases and related anxiety-depressive syndromes (Alzheimer’s disease, Huntington’s chorea, Parkinson’s disease), urinary incontinence, in particular urinary incontinence related to stress and enuresis, drug addiction and in particular addiction to tobacco, in particular to nicotine, to alcohol, to narcotics, to drugs, to analogues used in weaning-off from these addictive substances.

More specifically, the object of the present invention concerns the use of a mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, for the preparation of a drug intended to treat or to prevent depression or depressive state while limiting the risks of cardiovascular disturbances and/or while limiting organ and/or tissue toxicity, in particular hepatic and/or renal toxicity. In the context of the present invention, the term “depression” is understood to refer to a constellation of symptoms having, on the one hand, a psychological aspect consisting of mood disorders with pessimism, moral suffering, thoughts of death or suicide, mental inhibition, and on the other hand, a physical aspect of motor deficit, consisting in particular of a slowdown in motor activity, of appetite disturbances, of constipation, of sleep disturbances and of weight-control disturbances. Depression therefore corresponds to pathological psychological state combining a painful mood-alteration and a reduction in mental and motor activity. The term “depressive state” is understood to refer to a mental state characterised by a decline in neuropsychological tonicity, manifesting as lassitude, tendency to fatigue, discouragement and tendency to pessimism sometimes accompanied by anxiety.

Furthermore, the object of the present invention concerns more specifically the use of a mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, for the preparation of a drug intended to prevent or to treat fibromyalgia and/or chronic fatigue syndrome while limiting the risks of cardiovascular disturbances and/or while limiting organ and/or tissue toxicity, in particular hepatic and/or renal toxicity. Fibromyalgia syndrome is a chronic syndrome characterised by a feeling of pain and burning with morning stiffness mainly affecting articular and peri-articular fibrous tissues, and by a feeling of deep fatigue. Fibromyalgia includes a constellation of symptoms. The most frequent are non-restorative sleep, headache, digestive disturbances, depressive state, muscle spasm, facial pain, numbness etc. Chronic fatigue syndrome is characterised by a state of exhaustion or of fatigue. The most common symptoms are a state of weakness, spams and/or muscle pain, excessive need for sleep, fever, angina, memory loss and/or difficulty concentrating, insomnia, depression.

In addition, the object of the present invention concerns more specifically the use of a mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, for the preparation of a drug intended to prevent or to treat pain and in particular chronic pain while limiting the risks of cardiovascular disturbances and/or while limiting organ and/or tissue toxicity, in particular hepatic and/or renal toxicity. Pain may be associated with various disorders and/or wounds. It may be acute or chronic. Epidemiological studies have demonstrated the relations between states of chronic pain and anxiety depression. Thus, patients suffering from chronic pain may develop emotional problems that lead to depression, and, in the worst cases, to a suicide attempt. A patient is considered to be in chronic pain if he/she complains of suffering for a period of more than six months. Among the various forms of chronic pain, the followed should be mentioned by way of example, but not limited to these pain associated with fibromyalgia and/or arising in fibrous tissues, muscles, tendons, ligaments and other sites, abdominal pain and diarrhea in irritable bowel syndrome, as well as lower back pain.

In addition, the object of the present invention concerns more specifically the use of a mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, for the preparation of a drug intended to prevent or to treat urinary incontinence and in particular urinary incontinence related to stress and enuresis, while limiting the risks of cardiovascular disturbances and/or while limiting organ and/or tissue toxicity, in particular hepatic and/or renal toxicity.

Prophylactic and therapeutic treatment of the above-mentioned disorders is achieved by administering to an animal, preferentially to a man, a therapeutically-effective quantity of a mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, alone or in association with at least one other active substance. In most cases, this concerns man, however the treatment is also adapted to animals, in particular breeding animals (livestock, rodents, poultry, fish, …) and to domestic animals (dogs, cats, rabbits, horses, …).

The mixture of enantiomers, enriched in the dextrogyral enantiomer, of milnacipran and/or of at least one of its metabolites, as well as their pharmaceutically-acceptable salts, as previously described, is advantageously administered to patients receiving simultaneously, separately or staggered in time at least one other active compound in the treatment of the above-mentioned disorders.
Preferentially, the object of the present invention also includes, for use as a drug:

a) the said mixture of enantiomers enriched in the dextro-gyrual enantiomer of milnacipran and/or of at least one of its metabolites as well as their pharmaceutically-acceptable salts, and

b) at least one active compound chosen among the psychotropics, in particular antidepressants, and antimuscarinic agents as associated products for use simultaneously, separately or staggered in time in the treatment or the prevention of depression, in particular deep depression, resistant depression, depression in the elderly, psychotic depression, depression induced by treatment with interferon, depressive state, manic-depressive syndrome, seasonal depressive episodes, depressive episodes related to general health status, depressive episodes related to mood-altering substances.

The term “psychotropic” is understood to designate a substance of natural or artificial origin capable of modifying mental activity and whose action is essentially exerted on the central nervous system and the psychological state. Psychotropics are divided into three groups: 1) psycholeptics (hypnotics, neuroleptics and anxiolytics), 2) psychoanalpeutics (antidepressants and psychotonic) and 3) psychodylepictics (hallucinogenics).

Preferentially, the said psychotropic is an antidepressant. By way of example, but not limited to these, the antidepressant is chosen among (i) monoamine oxidase inhibitors (MAOIs) such as iproniazid, pargyline, seleagine, (ii) SHT1/T1-D-agonists such as sumatriptan, ephedrine and norpinephrine (alpha and beta sympathomimetics), (iii) tricyclic antidepressants, such as imipramine, clomipramine, (iv) selective serotonin reuptake inhibitors (SSRIs) such as fluoxetine, (v) selective norepinephrine reuptake inhibitors, such as for example tandamine, fluvoxamine, mirtazapine, (vi) serotonin norepinephrine reuptake inhibitors, such as venlafaxine and duloxetine. By way of example, but not limited to these, the antimuscarinic agent is chosen among piperidine, phenylalkylamines, oxotremorine, tropium, darifenacine, teinverine, iprotropium.

Preferably, the object of the present invention also includes for use as a drug:

a) the said mixture of enantiomers enriched in the dextro-gyrual enantiomer of milnacipran and/or of at least one of its metabolites as well as their pharmaceutically-acceptable salts, and

b) at least one active substance chosen among the active compounds inducing organ toxicity and the active compounds inducing tissue toxicity, in particular hepatic and/renal toxicity or with one or more active substances intended for treatment of hepatic or renal insufficiency as associated products for use simultaneously, separately or staggered in time in the treatment or the prevention of conditions or disorders that can be managed by double inhibition of serotonin (5-HT) and norepinephrine (NE) reuptake.

Preferably, the object of the present invention also includes, for use as a drug:

a) the said mixture of enantiomers enriched in the dextro-gyrual enantiomer of milnacipran and/or of at least one of its metabolites as well as their pharmaceutically-acceptable salts, and

b) at least one active substance chosen among active compounds inducing cardiovascular side-effects or compounds given to treat a heart condition as associated products for use simultaneously, separately or staggered in time in the treatment or the prevention of conditions or disorders that can be managed by double inhibition of serotonin (5-HT) and norepinephrine (NE) reuptake.

Advantageously, the cardiovascular side-effects induced are those mentioned previously, and more specifically, arterial hypertension, hypotension, cardiac rhythm disorders (tachycardia, bradycardia, palpitations).

The object of the present invention also includes pharmaceutical compositions containing the associated products previously described.

In the context of the present invention, the mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, is advantageously administered, but not in a limited manner, via the oral route, the nasal route, the transdermal, rectal, intestinal or parenteral route, by intramuscular, subcutaneous or intravenous injection, alone or in association with other active substances, as previously described.

When administered alone, the mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, may be administered per se or in the form of a pharmaceutical composition in which the said mixture of enantiomers or of their pharmaceutically-acceptable salts, is combined or mixed with one or several media, pharmaceutically-acceptable excipients and/or diluents, particularly to enhance bioavailability.

When the mixture of enantiomers in accordance with the invention, and preferentially the substantially-pure dextrogural F2695 enantiomer of milnacipran is administered in association with other active substances, the said mixture and the other active substances may be formulated as a mixture or separately in an identical or different form. They may be administered via the same or a different route.

The pharmaceutical composition in accordance with the invention may be formulated in a conventional manner well-known to the man skill in the art using one or more physiologically-acceptable media including excipients, adjuvants and additives such as for example preservatives, stabilisers, wetting agents or emulsifiers. The method of formulation chosen depends on the desired route of administration.

In the context of administration by injection, an aqueous solution is advantageously used, in particular a physiologically-acceptable buffer solution, such as Hank’s solution, Ringer’s solution or physiological saline solution. In the context of transdermal administration or via the mucous membranes, penetrating agents appropriate to the mucous membrane to be crossed are advantageously used. Such penetrating agents are well known to the man skill in the art. In the context of oral administration, the pharmaceutical compositions in accordance with the invention are advantageously administered in unit-dose or multiple-dose administration forms in mixtures containing appropriate pharmaceutical media known to the man skill in the art. Appropriate unit-dose administration forms include in particular tablets, possibly scored, capsules, powders, granules, oral solutions or suspensions, and aerosols. Appropriate multiple-dose administration forms include in particular drinkable drops, emulsions and syrups.

In the preparation of tablets, the mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, is formulated with a pharmaceutically-acceptable vehicle such as in particular polyvinylpyrrolidone, carbopol gel, polyethylene glycol, gelatine, talc, starch, lactose, magnesium stearate, gum arabic or their analogues. By way of example, the tablet contains the following excipients: calcium hydrogen phosphate dihydrate, calcium carmellose, povidone K30, anhydrous colloidal silicon dioxide, magnesium stearate, talc. The tablets may also be
coated, that is to say, covered with several coats of various substances such as saccarose in order to facilitate swallowing or preservation. The coating may also contain dyes or colorants in order to differentiate and to characterise the tablets with regard to their dosage strength, for example. The tablets may also be prepared in a more or less complex formulation intended to modify the rate of release of the active substance. Release of the active substance of the said tablet may be rapid, sustained or delayed depending on the desired absorption. Thus, the mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, may be prepared in a pharmaceutical form for sustained release obtained according to the process described in patent E18 939 626. This pharmaceutical form is presented in the form of multiparticles containing a large number of mini-granules and has a certain release profile in vitro.

Release of the mixture of enantiomers in accordance with the invention may be delayed and/or controlled by using an implant or by transdermal delivery, in particular subcutaneous or intramuscular, by intramuscular injection or by a transdermal patch. The said mixture is then formulated, in particular, with appropriate hydrophobic or polymeric substances and ion-exchange resins.

The quantity of the mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, to be administered to the patient depends on the condition to be treated, the desired effect, in particular a therapeutic or prophylactic effect, the health status and age of the patient, in particular his/her medical history of cardiovascular disease, the conditions of treatment and the method of administration of the drug. The quantity required to be administered for effective therapeutic or prophylactic use in a human patient can be determined based on animal models or on data known to the man skill in the art, obtained during the treatment of depression in man, for example, using a racemic mixture of Milnacipran.

In the context of therapeutic and/or prophylactic treatment of the disorders mentioned above, and in particular depression, depressive states, fibromyalgia, chronic fatigue syndrome, pain, the drug in accordance with the invention is advantageously administered at doses from 0.01 mg to 10 mg/kg body weight per day in one or more intakes, more advantageously at doses from 0.05 mg to 5 mg/kg body weight per day in one or more intakes, and even more advantageously at doses from 0.1 mg to 1 mg/kg body weight per day in one or more intakes. In a particularly advantageous manner, administration of the said medicinal product at such doses as those defined above is divided into two daily intakes, preferentially in capsule form. By way of example, the mixture of enantiomers in accordance with the invention, preferentially the substantially-pure F2695 enantiomer, is advantageously administered in the form of a capsule containing approximately 6.75 mg of active substance per capsule, 12.5 mg/capsule, 25 mg/capsule, 50 mg/capsule.

Other characteristics, aims and advantages of the inventions will become apparent in the examples that follow. The invention is not limited to these particular examples which are provided simply by way of example and which should be read in comparison with the following figures:

**BRIEF DESCRIPTION OF THE DRAWINGS**

**FIG. 1**: Effects of various treatments on heart rate following single administration (mean values)

**FIG. 2**: Effects of various treatments on mean values of diastolic blood pressure (mean values over 6 hours following the last intake, after 5 consecutive days of treatment).

**EXAMPLES**

**Example No. 1**

Pharmacokinetic Studies on Milnacipran and on its Enantiomers

Pharmacokinetic studies on milnacipran (F2207) and on its enantiomers (F2695 and F2696) were performed in various animal species and in man.

In animals, the pharmacokinetics of each enantiomer were studied following administration of the racemate or of a single enantiomer. Plasma concentrations of the F2695 and F2696 enantiomers are approximately equivalent in the animal species tested (monkey and rat).

A pharmacokinetic study in man involving 12 healthy subjects was performed by administering the racemate or one of the two enantiomers alone. It was shown that the pharmacokinetic profile of each enantiomer is independent of whether it was administered separately or in the form of the racemate, indicating the absence of interaction between the enantiomers (Table 1).

Cmax: Maximal plasma concentration directly estimated based on experimental data
Tmax: Time to reach maximal plasma concentration
AUC 0->∞: Area under the curve for plasma concentrations in relation to time extrapolated to infinity
T½: Terminal half-life of decrease in plasma concentrations

These findings indicate that no biotransformation of the F2695 or F2696 enantiomers was detected in the species studied.
Example N° 2

Biochemical Studies of Milnacipran and of its Enantiomers

The two enantiomers (F2695 and F2696) of milnacipran (F2207) were studied in vitro on uptake of norepinephrine and serotonin as well as on binding of paroxetine in the rat brain.

The presence of an asymmetrical carbon in the chemical structure of milnacipran lead to performance of a chiral study on the molecule. In order to study the various isomeric forms, the two enantiomers, F2695 (Zd) and F2696 (Zl), were separated starting from F2207 in its racemic configuration (Z.d.), and subjected to tests on uptake of monoamines, norepinephrine and serotonin, and on paroxetine binding.

2.1. Materials and Methods

2.1.1. Norepinephrine Uptake by a Homogenate (P₂) of Rat Hypothalamus.

Preparation of P₂

Male Sprague-Dawley rats, from 200 to 300 g, were stunned and decapitated, and the hypothalami were rapidly removed. Two hypothalami are homogenised in 4 ml of sucrose 0.32 M on a Potter S by 16 complete passes back and forth at 800 rpm, then centrifuged for 10 min at 1,000 g to eliminate cell debris. The supernate is centrifuged for 20 min at 10,000 g and the P₂ thus obtained is recovered in 4 ml of sucrose 0.32 M, and homogenised on a Dounce.

Uptake

³H-(1)-NE: 13 Ci/mmol (Amersham) is used.

Uptake takes place in a phosphate buffer (containing 8 g of NaCl, 1.21 g of K₂HPO₄ and 0.34 g of KH₂PO₄ per liter) pre-oxygenated 30 min before use with a mixture of O₂/CO₂ (95%/5%).

In 5-ml plastic tubes placed in a water bath at 37°C C, the following are introduced:

100 μl of buffer or inhibitor,
700 μl of buffer (containing 25 μM pargyline),
100 μl of P₂.

After temperature balance, the reaction begins by the addition of 100 μl of ³H-NE, 50 nM final concentration.

Exactly 10 min later, the reaction is stopped by adding 2.5 ml of chilled buffer and filtering through GF/F filters. The tube is then rinsed once and the filter once with 2.5 ml of chilled buffer. The filter is then introduced into a Beckman mini-vial and, after adding 3 ml of Instagel (Packard) liquid scintillator, radioactivity is measured with a Triecarb Packard scintillation counter.

Non-specific uptake (NS) is measured as the presence of DMI 10⁻⁵ M.

The IC₅₀ is determined graphically on the mean curve of percentage of inhibition (4 assays) in relation to the log of the concentration of inhibitor.

2.1.2. Serotonin Uptake

The method was developed following that of Gray and whittaker (1962, J. Anat., 96: 79-97). After homogenisation of brain tissue in a sucrose solution, the presynaptic terminals break away from the axon and close to form synaptosomes obtained by subcellular fractionation.

</table>

The three compounds were active in these three pharmacological assays, however differences were present:
in norepinephrine uptake:
F2695 was twice more active than F2207.
F2695 was 25 more active than F2696.

in serotonin uptake:
F2695 was 3 times more active than F2207.
F2695 was 12 times more active than F2696.

in paroxetine binding:
F2695 was 2 times more active than F2207.
F2695 was 10 times more active than F2696.

The three compounds were active in these pharmacological assays with however a lesser activity for the levogynral form (F2696) and the enantiomer (F2207). The dextrogonal form of milicparin (F2695) was 2 to 3 times more active than F2207.

Example No 3

Comparative Activity of Milicparin (F2207) and of its Active Enantiomer (F2695) by the Oral Route on Heart Rate and Blood Pressure in the Waking Dog

3.1. Introduction

This study was designed to study the effects of F2207 (batch n° PHA343) and of F2695 (batch n° PL-1-221) a) on heart rate after a single administration by the oral route, and b) on systolic and diastolic blood pressure after repeated administration for 5 days by the oral route in dogs.

This study was conducted at equally pharmaceutically-active doses of F2695 in 6 dogs equipped with implants (Data Sciences International) allowing for data on heart rate and blood pressure parameters to be captured by telemetry. The animals were allocated to 3 treatment groups:
group 1 (control) treated with water,
group 2 treated with F2207 at a dose of 20 mg/kg/day,
group 3 treated with F2695 at a dose of 10 mg/kg/day.

3.2. Methodology

Given the small number of equipped animals available, and in order to form 3 treatment groups comprising 6 animals each, the study was carried out in three series separated by a washout period with re-initialisation of the probes. Each series comprised 2 phases as follows:
the first phase of 5 days during which all the animals were treated with deionised water in order to adapt them to containment and to oral treatment by gavage with stomach tubing,
the second phase of 5 days during which the animals received their respective treatment.

The treatment regimen and associated schedule were as follows:
16 Sep. 2002 (D-7): reception of animals in the study,
18 to 22 Sep. 2002 (D-5 to D-1): adaptation treatment with deionised water for all the animals,
23 to 27 Sep. 2002 (D1 to D5): 1st treatment series: the animals received their respective treatment,
28 Sep. to 1 Oct. 2002 (D6 to D9): wash-out period,
2 to 6 Oct. 2002 (D10 to D14): adaptation treatment with deionised water for all the animals,
12 to 15 Oct. 2002 (D15 to D19): 2nd treatment series: the animals received their respective treatment,
16 to 20 Oct. 2002 (D20 to D24): adaptation treatment with deionised water for all the animals,

The allocation of animals to the various groups and the associated treatment are shown in table 3. The overall experimental plan is described in table 4.
The effects of the various treatments on blood pressure were analysed at the steady state, on D5, D29 and D33 (final effective day of treatment for each series). The analysis concerns the following data-capture times:

- Prior to treatment,
- every 30 minutes over 6 hours following treatment.

### 3.3. Results

#### 3.3.1. With regard to heart rate, a Tukey test was performed for each of the 13 experimental times.

The following observations were made in comparison with the control animals receiving deionised water (FIG. 1):

- A significant increase in heart rate for half of the experimental times (6/12) after single administration of F2207 (20 mg/kg/day), particularly marked one to two hours after treatment (p≤0.01 at 1.5 and 2.0 hours after treatment), followed by a slow decline, still present and significant however 5.5 hours after treatment (p≤0.01).
- The absence of any significant increase in heart rate for almost all the experimental times (11/12), after single administration of F2695 (10 mg/kg/day); one weak statistical significance was observed at 1.5 hours (p≤0.05).

#### 3.3.2. With regard to blood pressure, one mean value for diastolic blood pressure (FIG. 2 and table 5), as well as one mean value for systolic blood pressure (FIG. 3 and table 6) were calculated for each dog and for the 6 hours following the final treatment, after 5 consecutive days of administration. These mean blood pressure values were analysed by ANOVA followed by a Tukey test when ANOVA permitted such a test (data not shown).

The following were observed:

- A significant increase (p<0.001) in diastolic blood pressure after repeated administration of F2207 for 5 days (20 mg/kg/day) or of F2695 (10 mg/kg/day) compared to treatment with deionised water.
- A significant difference (p<0.05) in the mean diastolic blood pressure value after repeated administration of F2207 (20 mg/kg/day) for 5 days compared to the mean diastolic blood pressure value after repeated administration of F2695 (10 mg/kg/day).
- No significant effect on systolic blood pressure; it should be noted however that the values for sBP after repeated administration of F2695 for 5 days are close to the sBP following treatment with deionised water.

Individual diastolic and systolic blood pressure data are shown in tables 5 and 6 respectively.

3.4. Conclusion

Under the experimental conditions of the present study by oral administration in the waking dog equipped with a telemetry device:

- on single administration and compared to the control group, the increase in heart rate was weakly significant and fleeting with F2695 at a dose of 10 mg/kg/day, clearly significant and lasting with F2207 at the equally pharmaceutically-active dose of 20 mg/kg/day.

F2695, at a dose of 10 mg/kg/day, did not induce any statistically significant change in mean systolic blood pressure over the 6 hours following the final treatment, at the steady state after repeated administration for 5 days, a statistically significant difference was evidenced in mean diastolic blood pressure over the 6 hours following the final treatment, at the steady state after repeated administration for 5 days, between the active F2695 enantiomer (98±2 mm Hg) and the F2207 racemic at equally pharmaceutically-active doses (110±4 mm Hg).

These differences clearly demonstrated greater cardiovascular tolerability of the active F2695 enantiomer.

Example 4

Genomic Test of Predictive Toxicology In Vitro

4.1. Materials and Methods

The F2695 and F2696 compounds, enantiomers of the racemic molecule F2207, as well as clomipramine, a reference product (coded C218 in the study) were assessed in the present study. The two enantiomers, F2695 and F2696, were first assessed in a preliminary cytotoxicity test (MTT-assay) on primary rat hepatocytes, in order to select the three concentrations to be used in the final test.

After treatment of the primary rat hepatocytes in culture, the RNA was extracted in order to generate labelled comple-
mentary-DNA probes which were then hybridised on a membrane containing 682 alternatively-spliced fragments specific to cell stress. A Toxicity Index was obtained for each of the products by comparing the hybridisation profile of the treated cells with that of the untreated cells.

4.1.1. Purpose and Aim of the Study

Safe-Hit is a genomic test for predictive toxicopharmacology that is sensitive, robust, reliable, rapid and sure, enabling products to be compared and ranked on the basis of optimised assessment of their toxic potential.

Safe-Hit uses technology, the property of exon-in (DATASTM: Differential Analysis of Transcripts with Alternative Slicing), that permits isolation and, consequently, cloning of splicing events that result from a given biological state, in comparison with a control condition. This allows mRNA isoforms, differentially expressed depending the biological conditions, to be isolated.

Safe-Hit allows molecules within a chemical series to be ranked according to a Toxic Index, determined after the following basic steps (systematically performed in duplicate for each product):

- treatment of the cells lines with the various products at three different concentrations, deduced from a preliminary cytotoxicity test (MTT-assay); a reference concentration corresponding to 80% cell viability, a concentration 10-fold higher—when possible—and a concentration 10-fold lower,

preparation of total RNA and of the corresponding radio-labelled cDNA probes,

hybridisation of the cDNA probes: the Safe-Hit macroarray contains 682 independent clones, corresponding to alterations in gene splicing induced by overexpression of Wt p53 (p53 is the most ubiquitous "mediator" of cell stress, chosen for the development of this methodology), acquisition and determination of the Toxicity Index.
4.1.2. Cells
The cells used in the study (preliminary MTT-assay of cytotoxicity and the main test) are cryopreserved hepatocytes from Sprague-Dawley rats in primary culture (batches Hep184005 and Hep184006-Biopredic), cultured under standard conditions.

4.1.2.1 Culture Medium
Thawing medium: Leibovitz 15 medium with glutamax 1, to which were added 100 IU/ml of penicillin, 100 μg/ml of streptomycin and 0.6 M of glucose (batch MIL 210009-Biopredic),
seeding medium: Williams E medium with glutamax 1, to
which were added 100 IU/ml of penicillin, 100 μg/ml of streptomycin, 4 μg/ml of bovine insulin and 10% v/v foetal calf serum (batch MIL 260005-Biopredic),
incubation medium: Williams E medium with glutamax 1, to
which were added 100 IU/ml of penicillin, 100 μg/ml of streptomycin, 4 μg/ml of bovine insulin and 50 μM of hydrocortisone hemisuccinate (batch MIL 260009-260007-Biopredic).

4.1.2.2 Culture Conditions
37°C C., CO2 atmosphere (5%), relative humidity (95%).

4.1.3. Cytotoxicity Test
The cytotoxicity test (MTT-assay) detects live cells by use of a calorimetric reaction that reveals the integrity of cell respiration implying activity of the mitochondria. MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide), soluble in water, is transformed by splitting, under the effect of a mitochondrial enzyme in live cells, into insoluble purple formazan. Formazan is solubilised in an organic solvent and the solution obtained can be measured by spectrophotometry. The absorbance measured is proportional to the number of surviving cells.
The cells are put into contact with the product to be tested at 5 different concentrations (0.1-10-25-50 and 100 μM) for 16 hours.
After this period of exposure, an MTT solution (0.5 mg/ml in the incubation medium of the primary hepatocytes) is added for 3 hours. After solubilisation of the formazan crystals, the multi-well plates are read with a spectrophotometer at 500 nm in order to determine the percentage of cell viability.

4.1.4 Main Genomic Pharmacotoxicology Test
The main study is performed in duplicate, using seeded cultures exposed to each product in order to enhance consistency between the experiments and to validate the results obtained.

4.1.4.1 Cell Seeding and Treatment
The cells are seeded and cultured for 16 hours with each product, at the three concentrations chosen on the basis of the preliminary MTT-assay; two controls (untreated cells in solvent alone) are added to the series.

4.1.4.2 Total RNA Extraction and Assay
After treatment, the RNA is extracted and analysed as follows:
collection of cells and centrifugation, extraction performed with a ready-to-use phenol reagent (Trizol-batches 1106266 and 1121067-Invitrogen) according to the manufacturer’s protocol, solubilisation of the RNA in water, RNA assay by spectrophotometry (optical density measured at 260, 280 and 300 nm), verification of the quality of the RNA using Agilent.

4.1.4.3 Preparation of the cDNA Probes
The cDNA probes are prepared by reverse radio-active transcription (alpha dATP 32P-Amersham). The radio-active cDNA is quantified (Instant Imager-Packard) to ensure that the probes are active.

4.1.4.4 Hybridisation on the Safe-Hit Membrane
The 682 DATAS clones (alternately-spliced patterns) are placed on the Safe-Hit membranes, made of pre-cut nylon (Q-Biogene), with the aid of a Q-Pix apparatus (GENETIX). The DNA probes are hybridised on the membranes overnight and the membranes are washed.

4.1.5. Preparation of the cDNA Probes:
matrix: 5 μg of total RNA (for each treatment series and for each concentration),
primer: 100 ng of oligo-dTV oligonucleotide, for the 1st and 2nd hybridisations in rats (batch 12.00, Invitrogen),
mixture: 10 μl of First Strand 5x Premier buffer (batch 1131226-Invitrogen)
1 μl of dCTP+dGTP+dITTP 20 mM (batch 1105201-Invitrogen)
1 μM of ATP 120 μM (batch 1105201-Invitrogen)
5 μl of Dithiothreitol (DTT) 0.1 M (batch 133620-Invitrogen)
1 μl of Oligo U RNAse (batch 1113345-Invitrogen)
5 μl of 32P dATP 3 000 Ci/mmol 10 μCi/μl (batch B0239-Amersham)
4 μl of Superscript II (batch 1137806-Invitrogen)
1 μl of glycerogen (batch 1129328-Invitrogen)

Procedure:
Incubate the RNA and the oligo-dTV at 70°C for 10 minutes then place it on ice. Add 27 μl of MasterMix and incubate at 45°C for 1 h then at 50°C for 15 minutes. Add 20 μl of water, then 20 μl of EDTA 50 mM, then 4 μl of NaOH 10N. Incubate for 20 minutes at 65°C then place on ice.
Quantification: Instant Imager, Packard: 1 μl of reaction mixture, add 8 μl of acetic acid, 100 μl of isopropanol and 1 μl of glycerogen (20 μg/μl). Incubate at -20°C for 20 minutes, centrifuge for 20 minutes at 13000 rpm at 4°C. Reconstitute as a suspension with 200 μl of water, quantification: Instant Imager, Packard: 1 μl of reaction mixture.

Prehybridisation:
Aliquot 5 ml of prehybridisation buffer in the hybridisation tubes, add the corresponding volume of salmon-sperm DNA for a final concentration of 100 µg/ml, soak the membranes in 5×SSC, place the membrane in the hybridisation tube and prehybridise for 2 hours at 65°C.

Hybridisation:
Remove the prehybridisation buffer and rinse with 10-20 ml of 5×SSC; remove the 5×SSC, replace with 5 ml of buffer-salmon-sperm DNA, denature the RT probes for 5 min at 95°C, then place on ice for 1 minute, centrifuge to reconstitute, then recover the appropriate volume of denatured RT probes in the tube (100,000 to 200,000 cpm/ml), incubate overnight at 55°C.

Washing:
Rinse the membranes with 10-20 ml of washing buffer 1, remove the buffer and replace it with 50 ml of washing buffer 2, incubate for 30 min at 55°C, then remove and replace while washing with buffer 4, incubate for 30 min at 55°C, then pour off the final washing buffer, remove the membranes from the tubes, place them on a cassette and allow acquisition to continue for 3 hours.

4.1.4.5 Acquisition and Analysis of the Image
The membranes are placed on a screen (FX Imaging ScreenK-Bio-rad) for 3 hours. The film is then read using a Personal Molecular Imager FX (Bio-rad). The image is analysed using the Safe-Hit Reader Software (COSE).

4.1.4.6 Calculation of the Toxicity Index
All the data are transferred to an automatic calculation programme that normalises the various membranes and calculates a Toxicity Index, equal to the sum of the number of up- and down-regulated genes for a given compound at a given concentration, in comparison with the results of the untreated controls. The results of the two Safe-Hit analyses are then compared and combined to assess the potential toxicity of the various compounds tested. Two parameters that can be modified by the user are involved in the calculation of the Toxicity Index:

- Background Threshold (BT) smooths out weak signals, close to background noise and not attributable to significant gene expression. This therefore determines the threshold of detection;
- Induction Factor (IF) is determined as the multiplication factor, versus the control samples, for the clones to be up- or down-regulated. The value of this parameter is usually 2 or less than 2 in order to obtain relevant results. Progressively increasing the IF value selects those clones that are more and more strongly up- or down-regulated.

The procedure for calculating the Toxicity Index was developed by comparing the reference profiles (R: untreated cells) with an experimental profile (E) and goes through the following steps (see FIG. 4 for a schematic overview of the procedure):

- Transformation of all the values obtained into log values,
- Calculation of the mean log value for each of the duplicate assays (M_E and M_R), creation of a matrix with M_E and M_R for all the signals (+D), normalisation of the individual M_E values by subtracting from M_R the median of the 14 proximal values of Di (−NM_E), comparison of the normalised values with the reference values (C = NM_E − M_R), exponential transformation of C (rF), comparison of F_i with the Induction Factor chosen by the user:
  - if F_i > IF, the gene is considered to be up-regulated,
  - if 1/IF < F_i < IF, the gene is considered to be without change,
  - if F_i < 1/IF, the gene is considered to be down-regulated.

4.2. Results of the MTT-Assay
These assays were performed in triplicate on primary rat hepatocytes exposed for 16 hours.

Clomipramine, referred to as C218, showed marked toxicity at 100 µM since no cell viability was observed after exposure of the cells for 16 hours. Conversely, no toxicity was observed at 25 µM. At 50 µM, cell viability greater than 80% is entirely compatible with a genomic pharmacotoxicology study. The F2695 and F2696 compounds show no cytotoxicity in this assay, even at a concentration of 100 µM.

To perform the genomic pharmacotoxicological assessments, 3 concentrations of the same compound are used: the concentration which allows for 80% cell viability (C) to be obtained, as well as concentrations corresponding to (C)x10 and to (C)/10.

In order to compare the capacity of F2695 and F2696 to yield a score in the assay performed, the same concentrations were used in each test: 1 µM, 10 µM and 100 µM. Concentrations of 1 µM, 10 µM and 50 µM were used for clomipramine. See FIGS. 5A, 5B and 5C.

4.3 Results on Primary Rat Hepatocytes
Toxicity Indices (TI) were determined as described above. Only those clones which were found to be altered in relation to the control were taken into account in these indices, taking into consideration only those clones whose signal was two times higher than the background threshold (BT). Two separate analyses were performed using two levels of differentiation (Induction Factor-IF) in relation to the untreated controls:

- a factor of at least 1.7 in relation to the untreated controls;
- a factor of at least 2 in relation to the untreated controls.

This factor of 1.7 times represents the weakest value that allows an index not to be obtained in relation to the two untreated controls. This factor of 2 times allows the most robust signals to be taken into account.

4.3.1. Induction Factor of 1.7 in Relation to Untreated Control (Table 7)

</table>

The following ranking could thus be established, from the most toxic to the least toxic: C218 (clozapine) > F2696 > F2695.

Clozapine, the reference molecule, coded C218 in the present study, showed an increasing number of signatures with relation to the concentrations tested: respectively 9, 15 and 28 signatures at concentrations of 1, 10 and 50 µM (maximal concentration defined in the preliminary cytotoxicity test). As one might logically expect, all the signatures that occurred at low and moderate concentrations are also found at the higher concentrations.

At concentrations of 1 and 10 µM, F2695 did not induce any of the 682 potential signals of stress tested in the present study. At the highest concentration, 100 µM, only two signatures were detected, one of which was common to both F2695 and C218, but whose significance was unknown.

F2696 showed an increasing number of signatures in relation to the concentrations tested: 2, 5 and 22 signatures respectively at concentrations of 1, 10 and 100 µM. All of the signatures that occurred at the low and medium concentrations were detected at the higher concentrations. None of the 22 signatures was shared with F2695. Conversely, all 5 of the signatures that appeared at the low and medium concentration (including the 2 which were present at the low concentration) were among the 9 signatures detected with clozapine starting with the low dose, 1 µM. At the high concentration, 100 µM, 10 of the 26 signatures of F2696 were detected among the 28 signatures identified with clozapine at 50 µM.

From a qualitative standpoint, the impact of F2696 and of clozapine on mitochondrial transcripts, in particular on Cox1 and on cytochrome b, should be stressed. These signatures are not present with F2695 (G05/G09/101 positions).

</tbody>
</table>

According to these parameters, the following ranking could be put forward, from the most toxic to the least toxic: C218 (clomipramine) > F2696 >> > F2695.

With regard to over- and under-expressed clones at a Factor of 2, F2695 did not induce any signatures, even at a concentration of 100 µM.

The concentration effect on the occurrence of signatures was confirmed by the fact that the weak signatures with F2696 at 1 µM, which were present in the preceding analysis with the Factor of 1.7, disappear.

From a qualitative standpoint, the impact of F2696 and of clomipramine on Cox1 and on cytochrome b was also confirmed (GO0009101 positions).

F2695, the pharmacologically-active enantiomer of F2207, was without significant impact in this test, whereas clomipramine is used as positive-control reference product.

Conversely, F2696, the pharmacologically-inactive enantiomer of F2207, showed a profile of signatures that is quantitatively and qualitatively close to that of clomipramine, and shows no signatures in common with F2695.

All of this is evidence of a superior toxico-genomic profile for the active F2695 enantiomer which, in this experimental model, had a very significantly better safety coefficient that that of F2696.

4.4 Conclusion

The genomic pharmacotoxicology studies performed on the F2695 and F2696 molecules, enantiomers of F2207 (at concentrations of 10, 50 and 100 µM), and on C218 (clomipramine, at concentrations of 1, 10 and 50 µM), using rat hepatocytes in primary culture, yielded concentration-dependent stress signatures and Toxicity Indices. These studies confirm the capacity of the genomic pharmacotoxicology test to reveal stress signatures under treatment conditions (concentrations, duration of treatment) that do not cause any toxicity in a classic cell-viability assay such as MTT-assay.

This study brings to light several important facts: in the primary rat hepatocyte model, only F2695, the pharmacologically-active enantiomer of F2207, did not induce a significant Toxicity Index.

F2696, the pharmacologically-inactive enantiomer of F2207, and clomipramine, the reference psychotropic product, induced marked indices involving very similar or common stress signatures. In this system, clomipramine, the positive-control reference product, induced the highest number of stress signatures, significant indices having been observed starting at the lowest concentrations. On this subject, it is interesting to note that clomipramine can induce a certain number of adverse events in man, such as tachycardia, orthostatic hypotension, cardiac conduction or rhythm disturbances, and exceptionally hepatitis. In case of accidental overdose with clomipramine, syncope, haematological disturbances and severe cardiovascular manifestations can be observed.

Without inferring a common physiopathological mechanism, it is interesting to note that F2696 showed very similar or common stress signatures to those of clomipramine and also induces adverse events such as the cardiovascular disturbances previously described.
Thus, it is legitimate to suggest that the signatures observed are independent of any antidepressant, or more broadly psychotropic, profile. On the contrary, the signatures should indeed be considered to be "signatures of stress" (F2696 causes in particular reduced expression of a gene involved in protein synthesis and of a translation initiation factor). All of this is evidence of a superior toxicogenomic profile for the active F2695 enantiomer which, in this experimental model, had a very significantly better safety coefficient that that of F2696.

The invention claimed is:
1. A method for treating a patient afflicted with a condition or disorder which may be treated by double inhibition of serotonin (5-HT) and norepinephrine (NE) reuptake, while limiting the risks of cardiovascular disturbances and/or the risks of organ and/or tissue toxicity, comprising the step of administering to the patient an amount of enantiomers of milnacipran hydrochloride (Z(-)-2-(aminomethyl)-N,N-diethyl-1-phenylcyclopropene-carboxamide hydrochloride), such mixture being substantially pure in the dextrogyral enantiomer, effective for alleviation of the condition or disorder, wherein the administration of said mixture limits the risks of cardiovascular disturbances and/or the risks of organ and/or tissue toxicity, relative to administration of racemic milnacipran hydrochloride.
2. The method of claim 1, wherein the cardiovascular disturbance corresponds to an increase in blood pressure and/or an increase in heart rate.
3. The method of claim 2, wherein the increase in blood pressure corresponds to an increase in diastolic blood pressure.
4. The method of claim 1, wherein the organ toxicity is cardiac toxicity and the tissue toxicity is hepatic and/or renal toxicity.
5. The method of claim 1, wherein mass/mass ratio between the dextrogyral enantiomer and levogyrang enantiomer in the mixture is greater than 95:5 (dextrogyral:levogyrang).
6. The method of claim 1, wherein mass/mass ratio between the dextrogyral enantiomer and levogyrang enantiomer in the mixture is greater than 99:1 (dextrogyral:levogyrang).
7. The method of claim 1, wherein mass/mass ratio between the dextrogyral enantiomer and levogyrang enantiomer in the mixture is greater than 95:5:0.5 (dextrogyral:levogyrang).
8. The method of claim 1, wherein the disorder or condition is selected from depression, bi-polar disease, schizophrenia, generalised anxiety, morose and parasomic states, stress-related diseases, panic attacks, phobias, obsessive-compulsive disorders, behavioural disorders, oppositional disorders, post-traumatic stress disorder, depression of the immune System, fatigue and the associated pain syndromes, chronic fatigue syndrome, fibromyalgia, and other functional somatic disorders, autism, disorders characterised by attention deficit due to general health status, attention disorders due to hyperactivity, eating disorders, neurotic bulimia, neurotic anorexia, obesity, psychotic disorders, apathy, migraine, pain, irritable bowel syndrome, cardiovascular diseases, neuro-degenerative diseases and the associated anxiety-depressive syndromes (Alzheimer’s disease, Huntington’s chorea, Parkinson’s disease), urinary incontinence and drug addiction.
9. The method of claim 8, wherein depression is selected from deep depression, resistant depression, depression induced by treatments with interferon, depressive state, manic-depressive syndrome, seasonal depressive episodes, depressive episodes related to general health status, depression related to mood-altering substances.
10. The method of claim 8, wherein the phobia is agoraphobia.
11. The method of claim 8, wherein the pain is chronic pain.
12. The method of claim 8, wherein the cardiovascular disease is selected from anxiety-depressive syndrome in myocardial infarct or in hypertension.
13. The method of claim 8, wherein the urinary incontinence is selected from urinary incontinence related to stress and enuresis.
14. The method of claim 8, wherein the drug addiction is selected from addiction to tobacco, to nicotine, to alcohol, to narcotics, to drugs, and to an analogic used in weaning-off from these addictive states.
15. The method of claim 1, wherein the patient is selected from children, the elderly, patients with hepatic and/or renal insufficiency, patients receiving treatment that induces hepatic or renal organ and/or tissue toxicity, patients receiving treatment for a heart condition, patients receiving treatment that induces cardiovascular side-effects, patients having a history of cardiovascular disease and/or suffering from cardiovascular disorders.
16. The method of claim 15, wherein the history of cardiovascular disease and/or cardiovascular disorders is chosen among myocardial infarct, cardiac rhythm disorders (tachycardia, bradycardia, palpitations), blood pressure disorders (hypotensive or hypertensive patients) and heart disease.
17. A method for treating a patient afflicted with depression, while limiting the risks of cardiovascular disturbances and/or the risks of organ and/or tissue toxicity, comprising the step of administering to the patient an amount of:
a) a mixture of enantiomers substantially pure in the dextrogyral enantiomer of milnacipran hydrochloride (Z(-)-2-(aminomethyl)-N,N-diethyl-1-phenylcyclopropene-carboxamide hydrochloride), wherein the administration of said mixture limits the risks of cardiovascular disturbances and/or the risks of organ and/or tissue toxicity, relative to administration of racemic milnacipran hydrochloride, and
b) at least one active compound selected from the psychotropics,
as associated products for use simultaneously, separately or staggered in time, effective for alleviation of depression.
18. The method of claim 17, wherein the psychotropics are selected from antidepressants and antimuscarinic agents.
19. The method according to claim 17, wherein the depression is selected from deep depression, resistant depression, depression induced by treatments with interferon, depressive state, manic-depressive syndrome, seasonal depressive episodes, depressive episodes related to general health status, depression related to mood-altering substances.
20. A method for treating a patient afflicted with a condition or disorder which may be treated by double inhibition of serotonin (5-HT) and norepinephrine (NE) reuptake, while limiting the risks of cardiovascular disturbances and/or the risks of organ and/or tissue toxicity, comprising the step of administering to the patient an amount of:
a) a mixture of enantiomers substantially pure in the dextrogyral enantiomer of milnacipran hydrochloride (Z(-)-2-(aminomethyl)-N,N-diethyl-1-phenylcyclopropene-carboxamide hydrochloride), wherein the administration of said mixture limits the risks of cardiovascular disturbances and/or the risks of organ and/or
tissue toxicity, relative to administration of racemic milnacipran hydrochloride, and
b) at least one other active substance selected from the active compounds that induce organ toxicity and the active compounds that induce cell toxicity, as associated products for use simultaneously, separately or staggered in time, effective for alleviation of the condition or disorder.

21. The method of claim 20, wherein the cell toxicity is hepatic and/or renal toxicity.

22. A method for treating a patient afflicted with a condition or disorder which may be treated, by double inhibition of serotonin (5-HT) and norepinephrine (NE) reuptake while limiting the risks of cardiovascular disturbances and/or the risks of organ and/or tissue toxicity, comprising the step of administering to the patient an amount of:
a) a mixture of enantiomers substantially pure in the dextrogyral enantiomer of milnacipran hydrochloride (Z(+)2-(aminomethyl)-N,N-diethyl-1-phenylcyclopropanecarboxamide hydrochloride), wherein the administration of said mixture limits the risks of cardiovascular disturbances and/or the risks of organ and/or tissue toxicity, relative to administration of racemic milnacipran hydrochloride, and
b) at least one other active substance selected from the active compounds that induce cardiovascular side-effects, as associated products for use simultaneously, separately or staggered in time, effective for alleviation of the condition or disorder.

23. The method of claim 8, wherein the disorder or condition is depression and wherein the mixture of enantiomers is administered as a sustained release pharmaceutical form having a dose ranging from 0.01 mg/kg to 10 mg/kg body weight per day in one or more intakes.

24. The method of claim 23, wherein the sustained release pharmaceutical form has a dose ranging from 0.05 mg/kg to 5 mg/kg body weight per day in one or more intakes.

25. The method of claim 24, wherein the sustained release pharmaceutical form has a dose ranging from 0.1 mg/kg to 1 mg/kg body weight per day in one or more intakes.
