(54) Title: ABSORBENT ARTICLE

WO 03/059224 A1

(57) Abstract: Absorbent article of pants-like shape, such as incontinence pants, comprising an elastic waist portion, an absorbent element (5), and a liquid-impermeable outer layer (3) which is intended to enclose the absorbent element on at least that side thereof which faces away from the wearer during use of the article. Said elastic waist portion is made from an elastic first piece (1) which is essentially rectangular and is intended to form the rear portion (8) and side portions (9, 10) of the pants-like article. A second piece (2) forms the front portion (11) and crotch portion (12) of the pants-like article. Said second piece (2) is elongate, and the width thereof is, at least in the crotch portion (12), smaller than the length of the first piece (1). The absorbent element (5) is in its entirety arranged on the second piece (2). The liquid-impermeable outer layer (3) is breathable, at least over a portion of this which covers the absorbent element (5).

ABSORBENT ARTICLE

TECHNICAL FIELD

5 The present invention relates to an absorbent article of pants-like shape, such as incontinence pants, nappy pants or sanitary towel pants, comprising an elastic waist portion, an absorbent element, which has a length and a width and is intended to at least cover the genitals of the wearer during use of the article, and a liquid-impermeable outer layer which is intended to

10 enclose the absorbent element on at least that side thereof which faces away from the wearer during use of the article. The invention also relates to a method of manufacturing such absorbent articles of pants-like shape.

BACKGROUND ART

15 Absorbent disposable products for taking up urine, faeces or menstrual blood have developed greatly since they came into more general use during the 1960s and 1970s. As they are disposable products, it is necessary that they can be manufactured and sold at a very low price. At the same time, it is

20 important that the products function well and reliably. Good fit and comfort are also important characteristics. The first disposable nappies were made of two-part products, consisting of an outer pant made of plastic, intended to be re-used, and a rectangular absorbent insert for disposable use. The absorbent material in these inserts initially consisted of cellulose tissue.

25 Later, better absorption materials made of what is known as fluff pulp made of cellulose were developed. The fit and comfort of these early nappies were poor. The products were unwieldy and uncomfortable for the wearer. Towards the end of the 1970s, the first complete disposable nappies arrived, that is to say nappies in which the absorption bodies were integrated with a

30 liquid-impermeable outer layer. The absorption materials have developed and improved, which has resulted in the possibility of the absorption bodies being adapted better to the anatomy of the wearer. Hourglass-shaped

absorption bodies with a narrower crotch portion between the two end portions are now predominant. The trend has also been towards increasingly thin products, which has been made possible by the inclusion of what are known as superabsorbent materials in the absorbent element. There are 5 many reasons why thinner and even smaller absorption bodies are desirable. A thinner, smaller absorption body is more comfortable and more discreet, which is especially important for adult incontinent wearers. A reduction in volume is also very important financially because the product then requires less storage space and is easier to transport and takes up less shelf space in 10 shops. This is important for the financial management of the shops, and if a manufacturer can produce products requiring less space in the shops than the products of the competitors, this affords a not inconsiderable competitive advantage. Moreover, there is increased pressure from authorities, in particular as far as disposable articles are concerned, to use as little material 15 as possible for the purpose of reducing the burden on the environment.

The smaller the absorption bodies become, the more important it becomes that the absorption bodies come to lie in the correct place directly in front of the genitals of the wearer and remain in place during use even when the 20 wearer is very active and moves a great deal. The demands of consumers for discretion, comfort and reliable functioning are also increasingly exacting. Requirements for the absorption element to come to lie correctly when put on and then be retained in the correct place have therefore increased the need for good fixing of the article on the body and the need for very good 25 adaptability to the body when the wearer moves, at the same time as requirements have increased for the article always to come to lie in the correct place when the article is put on the wearer. This has led to the development of what are known as nappy pants, which have elastic portions for improved fit and comfort and increased flexibility during movements of the 30 wearer compared with conventional absorbent articles.

An early patent publication relating to nappy pants of the disposable type is GB 2 112 267-A. However, this publication from 1983 discloses primitive nappy pants which did not become a commercial product. Not until the 1990s did absorbent articles of pants-like shape and construction become a major 5 commercial product. Pants-like articles now exist in the form of nappies for infants and nappies for adults and to some extent sanitary towel pants for absorption of menstrual fluid. Previously commercially available nappy pants have been designed in principle like conventional nappies with a front portion and a rear portion and also an intermediate crotch portion, the front and rear 10 portions being interconnected by a side seam between each leg opening and the waist opening of the pants. The nappy pants have been produced by plane nappy-like pieces being produced in a continuous web, the individual nappy pants being formed by nappy-like blanks being folded double and provided with said side seams to form nappy pants. These side seams 15 project laterally from the finished product and are undesirable because they project and interfere with the fit of garments worn over the top. On account of their shape, they are visible through garments worn on top of the nappy pants and fitting closely around the body. They can also snag in clothing and even cause tears in nylon tights. Such projecting side seams can also chafe 20 and give rise to pressure sores on wearers who spend a lot of time lying on their side.

WO 00/61049 has proposed improved nappy pants, in which the projecting sides seams have been eliminated. In this construction, the side seams have 25 been eliminated by virtue of elastic side portions extending continuously in one piece from the front portion of the nappy pants to their rear portion on both sides of the nappy pants. However, the nappy pants according to WO 00/61049 have a number of disadvantages. The nappy pants according to said publication have what is referred to as a chassis, which extends over the 30 entire nappy pants and forms the front portion, the crotch portion and the rear portion and is most reminiscent of a conventional nappy, and also said elastic side panels which each overlap the chassis at both the front and the rear on

the nappy pants. These overlapping portions do not serve any actual purpose on the finished product and are in fact undesirable because a lot of material is wasted, that is to say they are used for no other purpose than joining together. The overlapping, joined-together portions are less of a nuisance

5 and less uncomfortable for the wearer than the projecting side seams on previously known nappy pants. Owing to their unfavourable positioning, particularly at the rear, the overlapping portions can still give rise to a risk of chafing and back sores on wearers who spend a lot of time lying on their back. Another disadvantage of the nappy pants according to WO 00/61049 is

10 that said chassis is relatively large and, as this portion is relatively rigid at least in comparison with the elastic side portions of the nappy pants, the nappy pants as a whole are not as adaptable to the body of the wearer but there is a risk that the nappy pants will be displaced from their optimum position in relation to the body when a wearer lies in bed and moves. In

15 particular the rigid rear portion of the nappy pants can be displaced and pull both the crotch portion and the front portion from their optimum positions directly in front of the genitals of the wearer because the front and rear portion are essentially rigidly joined together in one piece with the crotch portion.

20

An essential problem with absorbent articles of pants-like shape is that conventional articles of this kind tightly enclose the area around the genitals of the wearer, whereby this area, when body fluids are excreted, becomes locally saturated with moisture and vapour, which has an adverse effect on

25 the skin of the wearer. In some cases disturbing skin irritation can occur. Furthermore, also minor chafing of the article against the skin of the wearer, in combination with a moist environment and during lengthy usage of the article, can give rise to sores on older people with flesh that heals poorly.

30 Breathable and vapour-permeable but liquid-impermeable materials for use in absorbent articles, such as nappies, incontinence products or sanitary towels, are previously known. Breathable materials can consist of perforated

plastic films, as described in US 5,628,737, or of micro-porous plastic films, as described in, for example, EP-A-0238200. Another example of breathable materials are so-called non-woven materials which are air-permeable and vapour-permeable and which, if required, have been treated with means to 5 improve the liquid-impermeability, as is described in EP-A-0196654. In absorbent articles of pants-like shape, with a fit which tightly encloses around the wearer, the need for air-permeability and vapour-permeability is especially important. This in combination with all the above-mentioned problems associated with absorbent articles of pants-like shape has resulted in a great 10 need to find a pants-like article which functions well in all respects and which, in addition, it is possible to manufacture rationally.

DISCLOSURE OF INVENTION

15 By means of the present invention, an improved absorbent article of pants-like shape has been produced.

An article of the type referred to in the introduction is to this end characterized in that said elastic waist portion is made from an elastic first 20 piece which is elongate in the extended state and is intended to partly surround the trunk of the wearer and to form the rear portion and side portions of the pants-like article, in that a second piece forming part of the article is designed to form the front portion and crotch portion of the pants-like article, in that said second piece is elongate with two opposite end edges 25 and two opposite longitudinal edges, in that the width of the second piece is, at least in the crotch portion, smaller than the length of the first piece, in that the second piece is arranged with its longitudinal direction at right angles in relation to the longitudinal direction of the first piece and is connected by a first end portion to one longitudinal edge portion of the first piece, centrally 30 thereon, in that one end portion of the first piece is connected to a first side edge portion of the second piece, and in that the other end portion of the first piece is connected in a corresponding manner to a second side edge portion

of the second piece, in addition to which the absorbent element is in its entirety arranged on the second piece, and that the liquid-impermeable outer layer is breathable.

- 5 By virtue of the fact that the entire rear portion as well is elastic and, together with the elastic side portions, forms a single continuous elastic first piece, the pants as a whole are more adaptable to body movements. Local irregularities are taken up and smoothed out by the continuous elastic piece and are not transferred to the more rigid parts of the front portion and crotch portion
- 10 located directly in front of the genitals of the wearer. Compared with conventional nappies and previously known absorbent articles of pants-like shape, the article according to the present invention affords superior fit and comfort. Most of the pants-like garment is completely smooth. The seams required are arranged at the transition between the front portion and the first
- 15 piece and at the transition between the first and the second piece in the crotch portion. These seams come to lie in places which are not subjected to any significant pressure during use of the article, and there is less risk of chafing and pressure sores caused by seams on the pants-like article. The risk of chafing, pressure sores or other skin irritation diminishes also due to
- 20 the fact that the article is air-permeable and vapour-permeable in front of the absorbent element where large quantities of liquid are absorbed locally.

The design of the absorbent article according to the invention in only two part pieces, where the absorbent element is in its entirety located on the second

- 25 part piece, affords greater freedom of choice with regard to manufacturing method compared with previously known articles of pants-like shape.

According to one embodiment, the invention is characterized in that the length of the second piece is greater than the width of the first piece, and in

- 30 that the projecting portion of the second piece formed by the length difference is in its entirety located below that side edge of the first piece which is the lower one during use of the article, and there forms the crotch

portion. According to another embodiment, the invention is in this connection characterized in that said projecting portion has a smaller width than the remainder of the second piece.

5 According to another embodiment, the invention is characterized in that the absorbent element extends in its longitudinal direction over the entire crotch portion and a little way up over the front portion in the direction of that side edge of the first piece which is the upper one during use of the article.

10 According to another embodiment, the invention is characterized in that the absorbent element is arranged so as to extend with its lower end portion only a little way over the crotch portion and over less than half the extent of said projecting portion. According to another embodiment, the invention is in this connection characterized in that the absorbent element tapers in the direction 15 of the crotch portion.

According to an embodiment in which the absorbent element extends over the crotch portion, the invention is characterized in that the absorbent element forms a concave shape with its side edge portions in the crotch area.

20 According to one embodiment, the invention is characterized in that said connected side edge portions and end portions of said first and second pieces are, before connection, arranged in an overlapping manner, with the inside of an overlapping portion being arranged against the outside of an 25 overlapped portion.

According to another embodiment, the invention is characterized in that the second piece includes a liquid-permeable inner layer and said liquid-impermeable outer layer, and in that the absorbent element is arranged 30 between said inner and outer layers, the inner and outer layers extending in the lateral direction and longitudinal direction outside the absorbent element and being interconnected there.

According to one embodiment, the invention is characterized in that the liquid-impermeable and breathable layer only covers the absorbent element. According to one particular embodiment, the invention is thereby 5 distinguished in that the absorbent element is made up of fibres and that the liquid-impermeable and breathable outer layer consists of an outer layer of hydrophobic fibres connected with the absorbent element.

According to one embodiment, the invention is characterized in that said 10 breathable portion has an MTVR-value between in the order of magnitude of 200-10000 g/m²/24h. The term MTVR stands for "Moisture Vapour Transmission Rate", i.e. the amount of vapour which can pass per unit area during a certain period of time. Said breathable portion suitably has an MTVR-value in the order of magnitude of 500-5000 g/m²/24h and most 15 preferably in the order of magnitude of 1000-3000 g/m²/24h.

Measurement of breathability has been performed with the method ASTM E96 and the measurement equipment Lyssy has been used.

20 According to one embodiment, the entire second piece is breathable.

According to a further embodiment, the first piece is rectangular, which simplifies the manufacturing.

25 According to one embodiment, the second piece has a concave portion between the first piece and up to said side edge portions of the second piece, wherein the concave portion forms cut-outs for the legs of the wearer. According to another embodiment, the second piece is, at least along a part 30 of its length, narrowing towards the first piece, wherein the narrowing portion forms cut-outs for the legs of the wearer.

According to one embodiment, the invention is characterized in that the second piece is essentially inelastic. The term inelastic here denotes that the front section, under normally occurring stresses, does not stretch.

- 5 According to another embodiment, the invention is characterized in that the elastic members are arranged along the edges of the second piece, along at least the crotch portion for the forming of leg elastics, intended to lie in sealing contact with the legs of the wearer. According to one embodiment, the invention is further characterized in that the elastic members extend from
- 10 an area in the rear portion where the elastic first piece and the second piece overlap each other and further along the crotch portion along the edges of the second piece in a direction towards the front portion, whereby the elastic members are effectively connected with the elastic first piece.
- 15 In such a design, the leg elastic is connected with the waist elastic in the first piece, which gives the pants-like article a good fit.

According to a further embodiment, the invention is characterized in that the absorbent element comprises superabsorbent material and is continuously narrowing in a direction towards the rear portion of the article, and that the concentration of superabsorbent material increases in the same direction.

According to a suitable embodiment, the invention is characterized in that the liquid-impermeable outer layer is breathable and vapour-permeable, and that

- 25 the rest of the article, over its entire area, is breathable and vapour-permeable.

According to a modified embodiment, the invention is characterized in that different portions of the article due to the choice of different materials or

- 30 degree of perforation have different degrees of breathability.

According to one embodiment, the invention is characterized in that the elastic first piece has a higher degree of breathability than the liquid-impermeable outer layer on the second piece.

- 5 A method of manufacturing an article of the type mentioned in the introduction is characterized according to the invention in that said elastic waist portion is made from an elastic first piece which is essentially rectangular in the extended state and is intended to partly surround the trunk of the wearer and to form the rear portion and side portions of the pants-like article, in that a second piece forming part of the article is designed to form the front portion and crotch portion of the pants-like article, in that said second piece is elongate with two opposite end edges and two opposite longitudinal edges, in that the width of the second piece is, at least in the crotch portion, smaller than the length of the first piece, in that the second piece is arranged with its longitudinal direction at right angles in relation to the longitudinal direction of the first piece and is connected by a first end portion to one longitudinal edge portion of the first piece, centrally thereon, in that one end portion of the first piece is connected to a first side edge portion of the second piece, and in that the other end portion of the first piece is connected in a corresponding manner to a second side edge portion of the second piece, and that the liquid-impermeable outer layer, which is intended to cover the absorbent element is formed from a breathable material. According to one embodiment, the method is in this connection characterized in that the absorbent element is in its entirety arranged on the second piece forming part of the article before said piece is connected to said first piece. According to a further embodiment, the method according to the invention is characterized in that the absorbent element, before being arranged on the second piece, is provided with a liquid-impermeable and breathable layer.

- 30 DESCRIPTION OF DRAWINGS

The invention will be described in greater detail below with reference to illustrative embodiments shown in the accompanying drawings, in which

5 Fig. 1 shows schematically a phase of the construction of an absorbent article according to a first embodiment.

Fig. 2 shows schematically in plane form an assembled article according to the first embodiment.

10 Fig. 3 shows the article according to Fig. 2 in perspective.

Fig. 4 shows a section along the line IV-IV in Fig. 1.

15 Fig. 5 shows schematically a phase of the construction of an absorbent article according to a second embodiment.

Fig. 6 shows in plane form an assembled article according to the second embodiment.

20 Fig. 7 shows in plane form an assembled article according to a third embodiment.

Fig. 8 shows in plane view an assembled article according to a fourth embodiment of the invention.

25 Fig. 9 shows schematically the distribution of superabsorbent material in one embodiment of an absorbent element belonging to the article.

30 Fig. 10 shows a section along the line X-X in Fig. 8.

As can be seen from Fig. 1, the article in the embodiment according to Fig. 1 comprises a first piece 1. This piece is elastically stretchable and is shown in Fig. 1 in a plane and even extended state, in which the elastic piece 1 is essentially rectangular. The elastic first piece 1 can be made from 5 conventional materials well-known to the person skilled in the art, such as woven elastic materials, elastic non-wovens, elastic laminates or elastic films. Another alternative is a material with prestressed elastic threads arranged on a supporting material, for example non-woven. The important factor is that the elastic piece is stretchable for a wearer when the article is put on, and that it 10 fits closely with suitable tightness around the wearer during use of the article. The tightness is of course regulated by means of size and elastic stretchability.

The article includes a second piece 2 which, as can be seen from Figs. 1 and 15 4, consists of an outer layer 3, an inner layer 4 and an absorbent element 5 arranged between these. In the embodiment in plane form shown in Fig. 1, this element is essentially triangular. The material selected for the absorption element is not critical, but it can be chosen from among materials or material combinations well-known to the person skilled in the art. For example, the 20 absorbent element can consist of cellulose fluff pulp with superabsorbent materials in powder or fibre form added in. The absorbent element can also consist of a foam material with or without superabsorbent material.

The outer layer 3 must be liquid-impermeable and breathable. The 25 breathable and liquid-impermeable layer 3 must have a so-called MTVR-value in the order of magnitude of 200-10000 g/m²/24h. The term MTVR stands for "Moisture Vapour Transmission Rate", i.e. the amount of vapour which can pass per unit area during a certain period of time. Measurement of breathability has been performed with the method ASTM E96 and the 30 measurement equipment Lyssy has been used.

The liquid-impermeable and breathable layer 3 can, for example, consist of a perforated polyethylene film, where the size of the holes has been chosen so that air and vapour may pass, but not liquid molecules. If an absorbent article with a more textile-like appearance is desired, a liquid-impermeable film in 5 combination with an outer fibre layer is suitable.

Breathable and vapour-permeable but liquid-impermeable materials for use in absorbent articles, such as nappies, incontinence products and sanitary towels, are previously known in different embodiments. Breathable materials 10 can, as mentioned above, consist of perforated plastic films. One example of such films is described in US 5,628,737. The liquid-impermeable and breathable outer layer 3 can also consist of micro-porous plastic films, as is described in, for example, EP-A-0238200. Another example of breathable materials are so-called non-woven which are air-permeable and vapour- 15 permeable and which, if required, have been treated with means to improve the liquid-impermeability, as is described in EP-A-0196654.

The liquid-impermeable outer layer 3 is breathable and vapour-permeable, as has been mentioned above. The elastic first piece is also breathable and 20 vapour-permeable. As this is not required to be liquid-impermeable it may be arranged with a higher degree of breathability than the liquid-impermeable outer layer.

The inner layer 4 can be made from a liquid-permeable non-woven. 25
The second piece 2 is elongate and is arranged with its longitudinal direction at right angles in relation to the longitudinal direction of the first piece 1. The second piece 2 is connected by one end portion 6 to one longitudinal edge portion 7 of the first piece 1, centrally thereon. The connection can be made 30 by means of, for example, adhesive, thermal bonding or ultrasonic bonding.

In Fig. 1, the arrows A and B illustrate how the first and second pieces are folded to form the absorbent article of pants-like shape shown in Figs. 2 and 3. The elastic piece 1 is folded in according to the arrows A shown to form the rear portion 8 and side portions 9, 10 of the article, while the second 5 piece is folded upwards according to the arrows B to form the front portion 11 and crotch portion 12 of the article.

As can be seen most clearly from Fig. 3, one end portion 13 of the first piece is arranged so as to be overlapped a little by a first side edge portion 14 of 10 the second piece, and the other end portion 15 of the first piece is in a corresponding manner arranged so as to be overlapped a little by a second side edge portion 16 of the second piece. These overlapping portions are interconnected by means of, for example, adhesive, thermal bonding or ultrasonic bonding. Alternatively the front portion and the crotch portion can 15 be arranged detachably along said overlapping portions 13, 14 and 15, 16. Such a detachable connection can be made by means of, for example, hook means (not shown), as a result of which the pants-like article can be opened and subsequently reclosed with the same fit and tightness.

20 In Fig. 4, the thickness of the second piece has been exaggerated for the sake of clarity. The figure shows an outer layer 3 consisting of a laminate of a plastic film 17 and a non-woven layer 18 arranged outside. The inner layer 4 can consist of a liquid-permeable non-woven of a type well-known to the person skilled in the art.

25 In the embodiment shown in Figs. 5 and 6, those parts corresponding to the same parts in the embodiment according to Figs. 1-4 have been provided with the same reference numbers. The only difference between the embodiment according to Figs. 5 and 6 and that described above is the 30 shape and extent of the absorbent element 5. In this second embodiment, the absorbent element 5 is hourglass-shaped in plane form, as can be seen most clearly from Fig. 5, the narrower portion being intended to be arranged

in the crotch of the wearer during use of the article. The upper end edge 19 of the absorbent element 5 is located directly adjacent to the lower edge portion 7 of the first elastic piece, which means that the absorbent element according to this second embodiment extends over the entire crotch area and

5 a little way up over the front portion 11, as can be seen from Fig. 6. Elastic members 23,24 are arcuately arranged along the side edges of the absorbent element 5 and extend, as is evident from Fig. 5, from the upper elastic first piece 1 and down over the crotch portion of the article. As is evident from Fig. 5, the end portions of the elastic members 23,24 bridge that end portion 6 of

10 the second piece which overlaps the first elastic piece 1. Thus, the elastic members are operatively connected, in the rear portion 8 of the article, with the first elastic piece 1. The opposite end of each elastic member 23,24 does not extend all the way to the side edges of the second piece 2, but are arranged so that the elastic members in the state of use of the article, which is shown in Fig.

15 6, do not reach all the way to the side portions 9,10 of the first elastic piece. The relationship is the same in the embodiments according to Figs. 2 and 3.

Suitably, the elastic piece 1 and the elastic members have an elastic characteristic which allows an extension of up to the order of magnitude of

20 twice the length with constant extension force. An absorbent article of a certain size can thereby be used on wearers of different sizes without the pressure from the elastic being varied, which in its turn leads to a very limited assortment of different sizes of the absorbent article being required in order to cover the need of sizes for wearers of different sizes.

25

In the embodiment shown in Figs. 5 and 6, the second piece 2 has been shaped rectangular. The second piece 2 may, of course, be provided with leg cut-outs which follow the curved elastic members and the curved edge portions of the hourglass-shaped absorbent element.

30

Fig. 7 shows a third embodiment which is slightly modified in relation to the first embodiment. The only difference is that a part piece 21 of the second

piece is made narrower than the remainder of the second piece, in which way a pants-like article with a narrower crotch portion is obtained, as can be seen from Fig. 7.

5 In the embodiment shown in Fig. 8, the parts corresponding to similar details in the other embodiments have been provided with the same reference numbers. The second piece 2 has a concave portion 22 which extends from the first piece 1 towards the side edge portions 14,16. These are, as in the above described embodiments, intended to be connected with the end portions 13
10 and 15 on the first piece 1.

The first piece 1 is formed of an elastic material and is intended during use of the article to achieve an elastic tightening around the waist of the wearer, which tightening keeps the article in place and gives it a good fit. In the embodiment
15 shown in Fig. 8, the elastic members 23,24 are arranged along both sides of the concave portion 22 for the forming of leg elastic, which during use of the article is intended to be in sealing contact with the legs of the wearer. In the shown embodiment, the elastic members 23, 24 extend from the elastic first piece 1 to the side edge portions 14,16. The completed, assembled, pants-like
20 article will thereby be elastically tight-fitting around both of the legs of the wearer. In this manner a good fit is obtained. If the elastic piece 1 and the elastic members 23,24 are formed so that they are elastically stretchable a longer distance, without the tension in the elastic piece 1 and in the elastic members 23,24 being increased to any considerable extent, the article can,
25 without any annoying chafing, be used by wearers of different sizes. In such a design, the number of requisite sizes can be kept down, which leads to savings and rational manufacturing compared to if there is a need for a larger assortment of sizes.

30 Fig. 9 schematically shows the absorbent element 5 according to a suitable embodiment. In order to avoid giving rise to annoying chafing in the crotch of the wearer, the absorbent element 5 has been designed as narrowing in that

direction which during use of the article is directed rearwards. A complication with this narrowing design is that the absorbent element is narrowest in that portion which during use of the article is situated substantially in front of the genitals of the wearer, in which portion the demand for absorption capacity is 5 greatest. To avoid the risk of leakage in the narrower portion of the absorbent element to the most practicable degree, the superabsorbent material, according to a suitable embodiment where the superabsorbent material is part of the absorbent element in the form of particles or fibres, has been arranged with an increasing concentration in said narrowing direction. This has been 10 illustrated in Fig. 9 with the number of shown dots in correspondence with a gradient of the number of superabsorbent particles per unit volume of the absorbent element 5 in said direction.

In Fig. 4 an embodiment is shown where the liquid-impermeable but breathable 15 outer layer 3 consists of a layer of the second piece. According to one embodiment, the liquid-impermeable outer layer is arranged only over the absorbent element, and forms an outer layer of said element. In Fig. 10 a cross section along the line X-X in Fig. 8 is shown, in order to illustrate this. The absorbent element is here enclosed in a liquid-permeable layer 26, for example 20 of non-woven, and of a liquid-impermeable and at the same time breathable layer 27, for example of a perforated plastic film. The two layers 26,27 extend beyond the absorbent element and a distance around it and are there interconnected. The unit formed by the absorbent element 5 and the two layers 26 and 27 is attached to the second piece 2 of the absorbent article, wherein 25 the liquid-permeable layer 26 has been connected to the second piece 2, as is shown in Fig. 10.

The invention is not limited to the illustrative embodiments described above, but a number of modifications are possible within the scope of the patent 30 claims below.

The absorption unit shown in Fig. 10, consisting of the absorbent element 5 and the layers 26 and 27, may be replaced with an absorbent foam material in one piece, which foam material is provided with an integral liquid-impermeable and at the same time air-permeable layer.

5

In Fig. 10 a separate liquid-impermeable layer 27 of the absorbent element is shown. Within the scope of the invention is also an embodiment where the absorbent element is made up of fibres, possibly with an admixture of SAP, and where the liquid-impermeable and breathable outer layer consists of an outer 10 layer of hydrophobic fibres connected with the absorbent element.

Within the scope of the present invention are absorbent articles, in which different portions of the article through choices of different materials or degree of perforations, have different degrees of breathability.

15

When the expression liquid-impermeable and breathable has been used in the above text, it also implies that the material in question also is vapour-permeable, but that it does not allow passage of liquid drops.

20 In the above illustrative embodiments, as is evident from Fig. 3, the side edge portions 14,16 of the second piece have been arranged on the outside of the end edge portions 13,15 of the first piece. It is, of course, possible to do the reverse, i.e. with the end edge portions 13,15 of the first piece farthest out. These two alternatives are to be preferred, even though it is within the scope of 25 the invention to obtain said connection by means of attaching the inside of each of the end edge portions of the first piece to the inside of each side edge portion of the second piece, or by means of connecting corresponding edge portions outside to outside.

30 The article according to the invention has turned out to be especially suitable as incontinence shields for men. Other applications, such as menstrual shields or incontinence shields for women, are also conceivable.

In the above described illustrative embodiments, the highest absorption capacity per unit area for the narrowest area has been achieved by means of varying the content of superabsorbent material. Another method of achieving

5 higher absorption capacity in the narrowest area is to form the absorbent element with a higher basis weight in this area. This can, for example, be carried out on an absorbent element formed from a fluff pulp of cellulose. Thus, the absorption capacity for an absorbent element of a fluff pulp may also be controlled by varying the density and/or the thickness in different portions.

10 The absorbent element can, of course within the scope of the invention, be formed from other materials, for example absorbent foam materials.

CLAIMS

1. Absorbent article of pants-like shape, such as incontinence pants, nappy pants or sanitary towel pants, comprising an elastic waist portion, an absorbent element (5), which has a length and a width and is intended to at least cover the genitals of the wearer during use of the article, and a liquid-impermeable outer layer (3) which is intended to enclose the absorbent element on at least that side thereof which faces away from the wearer during use of the article,
- 10 characterized in,
that said elastic waist portion is made from an elastic first piece (1) which is elongate in the extended state and is intended to partly surround the trunk of the wearer and to form the rear portion (8) and side portions (9, 10) of the pants-like article,
- 15 in that a second piece (2) forming part of the article is designed to form the front portion (11) and crotch portion (12) of the pants-like article,
in that said second piece (2) is elongate with two opposite end edges and two opposite longitudinal edges, in that the width of the second piece is, at least in the crotch portion (12), smaller than the length of the first piece (1),
- 20 in that the second piece (2) is arranged with its longitudinal direction at right angles in relation to the longitudinal direction of the first piece and is connected by a first end portion (6) to one longitudinal edge portion (7) of the first piece, centrally thereon,
in that one end portion (13) of the first piece is connected to a first side edge portion (14) of the second piece, and in that the other end portion (15) of the first piece is connected in a corresponding manner to a second side edge portion (16) of the second piece, in addition to which the absorbent element (5) is in its entirety arranged on the second piece (2),
- 25 in that the liquid-impermeable outer layer (3), at least over a portion of this which covers the absorbent element, is breathable.
- 30 2. Absorbent article according to claim 1, characterized in,

that the length of the second piece (2) is greater than the width of the first piece (1), and in that the projecting portion of the second piece formed by the length difference is in its entirety located below that side edge of the first piece which is the lower one during use of the article, and there forms the 5 crotch portion (12).

3. Absorbent article according to claim 2, characterized in, that said projecting portion has a smaller width than the remainder of the second piece (2) (Fig. 7).

10

4. Absorbent element according to claim 2 or 3, characterized in, that the absorbent element (5) extends in its longitudinal direction over the entire crotch portion (12) and a little way up over the front portion (11) in the 15 direction of that side edge of the first piece (1) which is the upper one during use of the article.

5. Absorbent article according to claim 2 or 3, characterized in, 20 that the absorbent element (5) is arranged so as to extend with its lower end portion only a little way over the crotch portion (12) and over less than half the extent of said projecting portion (Fig. 2).

6. Absorbent article according to claim 5, characterized in, 25 that the absorbent element (5) tapers in the direction of the crotch portion (12).

7. Absorbent article according to claim 4, characterized in, 30 that the absorbent element (5) forms a concave shape with its side edge portions in the crotch area (Fig. 5).

8. Absorbent article according to any one of the preceding claims, characterized in,
that said connected side edge portions (13, 15) and end portions (14, 16) of
said first and second pieces (1 and, respectively, 2) are, before connection,
5 arranged in an overlapping manner, with the inside of an overlapping portion
being arranged against the outside of an overlapped portion.

9. Absorbent article according to any one of the preceding claims, characterized in,
10 that the second piece (2) includes a liquid-permeable inner layer (4) and said
liquid-impermeable outer layer (3), and in that the absorbent element (5) is
arranged between said inner and outer layers, the inner and outer layers
extending in the lateral direction and longitudinal direction outside the
absorbent element (5) and being interconnected there.

15

10. Absorbent article according to any one of claims 1-8, characterized in,
that the liquid-impermeable and breathable outer layer (3) only covers the
absorbent element.

20

11. Absorbent article according to any one of claim 10, characterized in,
that the absorbent element is made up of fibres and that the liquid-
impermeable and breathable outer layer consists of an outer layer of
25 hydrophobic fibres connected with the absorbent element.

12. Absorbent article according to any one of the preceding claims, characterized in,
that said breathable outer layer (3) has an MTVR-value between in the order
30 of magnitude of 200-10000 g/m²/24h.

13. Absorbent article according to any one of the preceding claims,
characterized in,
that said breathable outer layer (3) has an MTVR-value in the order of
magnitude of 500-5000 g/m²/24h.

5

14. Absorbent article according to any one of the preceding claims,
characterized in,
that said breathable outer layer (3) has an MTVR-value between in the order
of magnitude of 1000-3000 g/m²/24h.

10

15. Absorbent article according to any one of the preceding claims,
characterized in,
that the entire second piece (2) is breathable and vapour-permeable.

15 16. Absorbent article according to any one of the preceding claims,
characterized in,
that the first piece (1) is rectangular.

20 17. Absorbent article according to any one of the preceding claims,
characterized in,
that the second piece (2) has a concave portion (22) between the first piece
(1) and up to said side edge portions (14,16) of the second piece (2), wherein
the concave portion forms cut-outs for the legs of the wearer.

25 18. Absorbent article according to any one of the preceding claims,
characterized in,
that the second piece (2) is, at least along a part of its length, narrowing
towards the first piece (1), wherein the narrowing portion forms cut-outs for
the legs of the wearer.

30 19. Absorbent article according to any one of the preceding claims,
characterized in,

that the front portion(1) is essentially inelastic.

20. Absorbent article according to any one of the preceding claims, characterized in,
5 that elastic members (23,24) are arranged along the edges of the second piece (2), along at least the crotch portion for the forming of leg elastics, intended to lie in sealing contact with the legs of the wearer.
- 10 21. Absorbent article according to claim 20, characterized in, that the elastic members (23,24) extend from an area (6) in the rear portion where the elastic first piece (1) and the second piece (2) overlap each other and further along the crotch portion along the edges of the second piece in a direction towards the front portion, whereby the elastic members are effectively connected with the elastic first piece.
- 15 22. Absorbent article according to any one of the preceding claims, characterized in, that the liquid-impermeable outer layer (3) is breathable and vapour-permeable and that the rest of the article, over its entire area, is breathable and vapour-permeable.
- 20 23. Absorbent article according to claim 22, characterized in, that different portions of the article due to a choice of different material or degree of perforation have different degrees of breathability.
- 25 24. Absorbent article according to claim 23, characterized in, that the elastic first piece (1) has a higher degree of breathability than the liquid-impermeable outer layer on the second piece (2).
- 30 25. Absorbent article according to any one of the preceding claims, characterized in,

that the absorbent element (5) comprises superabsorbent material and is continuously narrowing in a direction towards the rear portion of the article and that the concentration of superabsorbent material increases in the same direction.

5

26. Method of manufacturing an absorbent article of pants-like shape, such as incontinence pants, nappy pants or sanitary towel pants, comprising an elastic waist portion, an absorbent element (5), which has a length and a width and is intended to at least cover the genitals of the wearer 10 during use of the article, and a liquid-impermeable outer layer (3) which is intended to enclose the absorbent element on at least that side thereof which faces away from the wearer during use of the article,
characterized in,
that said elastic waist portion is made from an elastic first piece (1) which is 15 essentially rectangular in the extended state and is intended to partly surround the trunk of the wearer and to form the rear portion (8) and side portions (9, 10) of the pants-like article, in that a second piece (2) forming part of the article is designed to form the front portion (11) and crotch portion (12) of the pants-like article,
20 in that said second piece (2) is elongate with two opposite end edges and two opposite longitudinal edges, in that the width of the second piece (2) is, at least in the crotch portion (12), smaller than the length of the first piece (1), in that the second piece is arranged with its longitudinal direction at right angles in relation to the longitudinal direction of the first piece and is 25 connected by a first end portion (6) to one longitudinal edge portion (7) of the first piece, centrally thereon, in that one end portion (13) of the first piece (1) is connected to a first side edge portion (14) of the second piece (2), and in that the other end portion (15) of the first piece (1) is connected in a corresponding manner to a second side edge portion (16) of the second piece, 30 and that at least a portion of the liquid-impermeable outer layer, which portion is intended to cover the absorbent element, is formed from a breathable material.

27 Method according to claim 26, characterized in,
that the absorbent element (5) in its entirety is arranged on the second piece
(2) forming part of the article before said piece is connected to said first piece
5 (1).

28. Method according to claim 27, characterized in,
that the absorbent element (5), before being arranged on the second piece
(2), is provided with a liquid-impermeable and breathable layer (27).
