COMPOSITE SOLE STRUCTURE

BACKGROUND

[0001] The current embodiments relate to the field of articles of footwear. More specifically, the current embodiments relate to a sole structure for articles of footwear.

[0002] Articles of footwear including various types of materials and sole structures have previously been proposed. For example, some articles of footwear may include materials forming a rigid sole structure, while other articles of footwear may include materials forming a flexible sole structure. However, a sole structure that is substantially rigid in some regions, while remaining flexible in other regions, may increase the wearer's ability to accelerate and/or change directions. In addition, a sole structure having components made of materials having varying configurations, thicknesses and lengths throughout the sole structure may reduce the overall weight of the article of footwear and enhance the performance of the wearer.

SUMMARY

[0003] Embodiments relating to a lightweight sole structure are disclosed. In some embodiments, the sole structure may include a lobed member having a protruding portion associated with a cleat member. In some embodiments, the sole structure may include a chambered member located in an indention in an intermediate member. In some embodiments, the sole structure may include a cleat member having an outer layer, an intermediate layer, and an inner layer. In some embodiments, a method of making a sole structure may include injecting a chambered member in between an upper member and an intermediate member. In some embodiments, the sole structure may include a plurality of zones having varying degrees of flexibility. In some embodiments, the sole structure may include cleat members having penetrating portions for penetrating into the ground surface.

[0004] In one aspect, a sole structure is disclosed. In one embodiment, the sole structure may include a bottom member having a top surface, a bottom surface, a forefoot region, a midsole region and a heel region, wherein the top surface of the forefoot region of the bottom member has a first protruding portion associated with a cleat member. In one embodiment, the sole structure may also include an intermediate member having a first projection, second projection, and third projection, the intermediate member further having a top surface, a bottom surface, a forefoot region, a midsole region and a heel region. In one embodiment, the first projection and second projection may be located in the forefoot region of the intermediate member and the third projection may extend through the midsole region into the heel region of the intermediate member. In one embodiment, the bottom surface of the first projection may have a second protruding portion associated with the cleat member. In one embodiment, the second protruding portion in the bottom surface of the first projection associates with the first protruding portion in the top surface of the bottom member.

[0005] In another aspect, a sole structure is disclosed. In one embodiment, the sole structure may include a bottom member having a top surface and a bottom surface. In one embodiment, the sole structure may also include an intermediate member having a top surface and a bottom surface, the intermediate member having an indentation that is concave relative to the top surface of the intermediate member, and the bottom surface of the intermediate member is attached to the top surface of the bottom member. In one embodiment, the sole structure may also include a chambered member configured to be inserted within the indentation on the top surface of the intermediate member.

[0006] In another aspect, a sole structure is disclosed. In one embodiment, the sole structure may include a bottom member having a bottom surface. In one embodiment, the sole structure may also include a cleat member associated with the bottom member, the cleat member having an outer layer, an intermediate layer, and an inner layer.

[0007] In another aspect, a method of making a sole structure is disclosed. In one embodiment, the method may include forming an upper member, wherein the upper member having a top surface, and a bottom surface. In one embodiment, the method may also include forming an intermediate member, wherein the intermediate member having a top surface and a bottom surface, wherein the top surface of the intermediate member includes a concave indentation. In one embodiment, the method may also include placing the top surface of the intermediate member in contact with the bottom surface of the upper member. In one embodiment, the method may also include injecting a chambered member into the indentation of the intermediate member, the chambered member having a honeycomb volume.

[0008] In another aspect, an article of footwear is disclosed. In one embodiment, the article of footwear may include a sole structure having a forefoot region, a midfoot region and a heel region, wherein the sole structure includes a plurality of layers. In one embodiment, the plurality of layers may include a first zone of flexibility located in the forefoot region. In one embodiment, the plurality of layers may also include a second zone of flexibility located in the forefoot region, wherein the second zone of flexibility is more rigid than the first zone of flexibility. In one embodiment, the plurality of layers may also include a third zone of flexibility located in the midfoot region, wherein the third zone of flexibility is more rigid than the first and second zone of flexibility.

[0009] In another aspect, a sole structure is disclosed. In one embodiment, the sole structure may include a bottom member having a forefoot region, midfoot region, heel region, to surface and bottom surface, the bottom surface of the bottom member forming an outer surface of the sole structure. In one embodiment, the sole structure may also include a cleat member extending from the bottom member, the cleat member including a penetrating portion that is configured to penetrate into a ground surface. In one embodiment, the sole structure may also include an intermediate member having a top surface and a bottom surface, the intermediate member configured to provide structural support for the sole structure. In one embodiment, the bottom surface of the intermediate member associates with the top surface of the bottom member, wherein a portion of the intermediate member extends into the penetrating portion of the cleat member.

[0010] In another aspect, a sole structure is disclosed. In one embodiment, the sole structure may include an upper member having a top surface and a bottom surface, the upper member having a first concave indentation in the top surface and a corresponding convex indentation extending from the bottom surface of the upper member. In one embodiment, the sole structure may also include an intermediate member having a top surface, the intermediate member having a second concave indentation in the top surface of the intermediate member, wherein the second concave indentation in the top surface of the intermediate member is configured to receive the convex indentation extending from the bottom surface of the upper member. In one embodiment, the sole structure may also include a chambered member configured to be inserted within the first concave indentation in the top surface of the upper member.

[0011] Other systems, methods, features and advantages of the current embodiments will be, or will become, apparent to those in the art upon examination of the following figures and detailed description. It is intended that all such additional systems, methods, features and advantages be included within this description and this summary, be within the scope of the current embodiments, and be protected by the following claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0012] The current embodiments can be better understood with reference to the following drawings and description. The components in the figures are not necessarily to scale, emphasis instead being placed upon illustrating the principles of the current embodiments. Moreover, in the figures, like reference numerals designate corresponding parts throughout the different views.

[0013] FIG. **1** is an exploded isometric view of one embodiment of a sole structure;

[0014] FIG. **2** is an isometric view of one embodiment of a Y-shaped honeycomb structure located in an indentation;

[0015] FIG. **3** is a partial view of one embodiment of a sole structure;

[0016] FIG. **4** is a perspective view of one embodiment of a sole structure illustrating several cross-sectional views at different points along a longitudinal length of the sole structure;

[0017] FIG. **5** is a cross-sectional view of along the longitudinal length of one embodiment of a sole structure showing the varying zones of flexibility;

[0018] FIG. **6** is a perspective view of one embodiment of a sole structure while in use;

[0019] FIG. **7** is an exploded isometric view of another embodiment of a sole structure having an indentation in the upper member;

[0020] FIG. **8** is an exploded isometric view of another embodiment of a sole structure having an upper member that extends over only a portion of the intermediate member in the forefoot region;

[0021] FIG. **9** is an exploded isometric view of another embodiment of a sole structure having an indentation in the upper member;

[0022] FIG. **10** is an exploded isometric view of another embodiment of a sole structure having a honeycomb layer;

[0023] FIG. **11** is an isometric view of one embodiment of a sole structure having two indentations in two components;

[0024] FIG. **12** is a cross-sectional view of one embodiment of a sole structure having cleat members in the forefoot region;

[0025] FIG. **13** is an isometric view of one embodiment of a sole structure having cleat members in the forefoot region;

[0026] FIG. **14** is an isometric view of one embodiment of a sole structure having cleat members in the heel region; and

[0027] FIG. **15** is an isometric view of another embodiment of a bottom member of a sole structure.

DETAILED DESCRIPTION

[0028] Conventional articles of athletic footwear include two primary elements, an upper and a sole structure. The upper may provide a covering for the foot that comfortably receives and securely positions the foot with respect to the sole structure. The sole structure may be secured to a lower portion of the upper and may be generally positioned between the foot and the ground. In addition to attenuating ground reaction forces (i.e., providing cushioning) during walking, running, and other ambulatory activities, the sole structure may influence foot motions (e.g., by resisting pronation), impart stability, allow for twisting and bending, and provide traction, for example. Accordingly, the upper and the sole structure may operate cooperatively to provide a comfortable structure that is suited for a wide variety of athletic activities.

[0029] The upper may be formed from a plurality of material elements (e.g., textiles, polymer sheets, foam layers, leather, synthetic leather) that may be stitched or adhesively bonded together to form a void on the interior of the footwear for comfortably and securely receiving a foot. More particularly, the upper may form a structure that extends over instep and toe areas of the foot, along medial and lateral sides of the foot, and around a heel area of the foot. The upper may also incorporate a lacing system to adjust the fit of the footwear, as well as permitting entry and removal of the foot from the void within the upper. In addition, the upper may include a tongue that extends under the lacing system to enhance adjustability and comfort of the footwear, and the upper may incorporate a heel counter.

[0030] FIG. **1** illustrates an exploded isometric view of an embodiment of sole structure **100**. The following discussion and accompanying figures disclose an article of footwear having a sole structure **100** forming a plate that includes, for example, an upper member, an intermediate member, a chambered member, and a bottom member. The article of footwear is disclosed as having a general configuration suitable for soccer or football. Concepts associated with the footwear may also be applied to a variety of other athletic footwear types, including running shoes, baseball shoes, basketball shoes, cross-training shoes, cycling shoes, football shoes, golf shoes, tennis shoes, walking shoes, and hiking shoes and boots, for example. The concepts may also be applied to footwear types that are generally considered to be non-athletic, including dress shoes, loafers, sandals, and work boots. Accordingly, the concepts disclosed herein apply to a wide variety of footwear types.

[0031] In some embodiments, the sole structure **100** may be associated with an upper (not shown). An upper may be depicted as having a substantially conventional configuration incorporating a plurality of material elements (e.g., textiles, foam, leather, and synthetic leather) that are stitched or adhesively bonded together to form an interior void for securely and comfortably receiving a foot. The material elements may be selected and located with respect to the upper in order to selectively impart properties of durability, air-permeability, wear-resistance, flexibility, and comfort, for example. In some embodiments, an ankle opening in the heel region provides access to the interior void. In some embodiments, the upper may include a lace that is utilized in a conventional manner to modify the dimensions of the interior void, thereby securing the foot within the interior void and facilitating entry and removal of the foot from the interior void. The lace may extend through apertures in the upper, and a tongue portion of the upper may extend between the interior void and the lace. Given that various aspects of the present discussion primarily relate to the sole structure **100**, the upper may exhibit the general configuration discussed above or the general configuration of practically any other conventional or non-conventional upper. Accordingly, the overall structure of the upper may vary significantly.

[0032] For consistency and convenience, directional adjectives are employed throughout this detailed description corresponding to the illustrated embodiments. The term "longitudinal" as used throughout this detailed description and in the claims refers to a direction extending a length of a component, such as a sole structure. In some cases, the longitudinal direction may extend from a forefoot portion to a heel portion of the component. Also, the term "lateral" as used throughout this detailed description and in the claims refers to a direction extending a width of a component. In other words, the lateral direction may extend between a medial side and a lateral side of the component, or along the width of the component. The terms longitudinal and lateral can be used with any component of an article of footwear, including a sole structure as well as individual components of the sole structure.

[0033] In some embodiments, sole structure **100** may be secured to the upper and has a configuration that extends between the upper and the ground. In addition to attenuating ground reaction forces (i.e., cushioning the foot), the sole structure **100** may provide traction, impart stability, and limit various foot motions, such as pronation.

[0034] Some embodiments may include provisions for providing structural support to the sole structure **100**. In some cases, rigid components may be associated with the sole structure **100**. In some embodiments, the rigid components may be associated with the entire length of the sole structure **100**. However, in other embodiments, the rigid components may be associated with only a portion of the sole structure **100**. In some embodiments, the sole structure **100** may include one rigid component, while other embodiments may include more than one rigid component. Rigid components may provide the wearer with support in order to accelerate, provide stability, and may limit various unwanted foot motions.

[0035] Some embodiments may include provisions for providing flexibility to the sole structure **100**. In some cases, flexible components may be associated with the sole structure **100**. In some embodiments, the flexible components may be associated with the entire length of the sole structure **100**. However, in other embodiments, the flexible components may be associated with only a portion of the sole structure **100**. In some embodiments, the sole structure may include one flexible component, while other embodiments may include more than one flexible component. Flexible components allow the foot to bend and twist in order to allow the wearer to quickly maneuver, to change directions or to more accurately position the wearer's foot in a desired position.

[0036] Some embodiments may include provisions for allowing flexibility in some regions of the sole structure **100**, while also allowing rigidity in other regions. In some cases, the flexible components may extend the entire length of the sole structure **100**. However, in other cases the flexible components may extend over only portions of the sole structure **100**. Similarly, in some cases, the rigid components may extend the entire length of the sole structure **110**. However, in other cases the rigid components may extend over only portions of the sole structure **100**. In some embodiments, rigid components may extend only into the heel and midsole region of the sole structure **100**, while flexible components extend over the entire length of the sole structure **100**, including the forefoot region. However, other embodiments may include flexible components extending over only the heel and midsole region, while the rigid components extend over the entire length of the sole structure **100**. In some embodiments, the length of each component is adjusted in order to achieve the desired rigidity or flexibility in each region of the sole structure **100**.

[0037] Some embodiments may include provisions for minimizing the overall weight of the sole structure **100**. In some embodiments, porous or chambered components may be associated with the sole structure **100** in order to reduce the overall mass and weight. In some embodiments, the porous or chambered components may form a layer in the sole structure **100**. However, in other embodiments, the porous or chambered components may be located in indentations or cavities in one or more of the other components in the sole structure **100**. In some embodiments, the overall weight of the sole structure **100** is reduced when a porous or chambered member displaces all or a portion of a heavier component.

[0038] Some embodiments may include provisions for adjusting the thickness of each component throughout the length of the sole structure **100**. In some embodiments, the rigid components may have increased thickness in regions of the sole structure **100** where more structural support is desired. In some embodiments, the rigid components may have decreased thickness in regions of the sole structure **100** where less structural support is desired. In some embodiments, the flexible components may have increased thickness in regions where more flexibility is desired, and may have decreased thickness in regions where less flexibility is desired. In some embodiments, porous or chambered components may have varying thickness throughout the length of the sole structure **100**.

[0039] Referring to FIG. **1**, some embodiments of the sole structure **100** may include an upper member **110**, a chambered member **120**, an intermediate member **130**, a bottom member **140** and a plurality of cleat tips **150**. In some embodiments, cleat tips **150** may include a first cleat tip **151**, a second cleat tip **152**, a third cleat tip **153**, a fourth cleat tip **154**, a fifth cleat tip **155** and a sixth cleat tip **156**.

[0040] In one embodiment, sole structure **100** may include an upper member **110**. In one embodiment, upper member **110** may be formed from a generally rigid material. FIG. **1** illustrates an upper member **110** having a top surface **119**, a bottom surface **121**, a forefoot region **111**, a midfoot region **124**, and a heel region **112**. It will be understood that forefoot portion **111**, midfoot portion **112** and heel portion **114** are only intended for purposes of description and are not intended to demarcate precise regions of sole structure **100**. In some embodiments, the upper member **110** is oriented so that the top surface **119** of upper member **110** is facing the wearer's foot. Upper member **110** may serve to add durability to sole structure **100** and to form a separation barrier between the remaining components and the wearer's foot.

[0041] In some embodiments, upper member **110**, intermediate member **130** and bottom member **140** may have one or more protruding portions. The protruding portions may include a depression or indentation that is concave relative to the top surface of the component, while extending out in a convex manner from the bottom surface of the component. Therefore, the term "protruding portion" as used throughout the specification and claims refers to the concave depression or indentation on the top surface of the component, as well as the corresponding convex surface on the bottom surface of the component. Referring to FIG. **1**, for example, protruding portion **135** forms a depression or indentation that is concave relative to the top surface **161** of intermediate member **130**, while also forming a convex surface **166** on the bottom surface **162** of intermediate member **30**.

[0042] In some embodiments, upper member **110** may include a plurality of protruding portions associated with the top surface **119** and bottom surface **121**. In some embodiments, the protruding portions include a depression on the top surface **119** of upper member **110**, and extend out in a convex manner from the bottom surface **121** of upper member **110**.

[0043] In some embodiments, the protruding portions may be associated with a cleat member. The term "cleat member" as used in this detailed description and throughout the claims includes any provisions disposed on a sole for increasing traction through friction or penetration of a ground surface. Typically, cleat members may be configured for any type of activity that requires traction.

[0044] Referring to FIG. **1**, upper member **110** may include a first protruding portion **113** and second protruding portion **114** located in the heel region **112**. FIG. **1** also shows a third protruding portion **115**, fourth protruding portion **116**, fifth protruding portion **117** and sixth protruding portion **118** in the forefoot region **111**. In some embodiments, the sixth protruding portion **118** may include a depression in the top surface **119** of upper member **110**, and extends down in a convex manner from the bottom surface **121** of upper member **110**. In some embodiments, first protruding portion **113**, second protruding portion **114**, third protruding portion, **115**, fourth protruding portion **116**, and fifth protruding portion **117** are similarly shaped.

[0045] In some embodiments, the number of protruding portions in upper member **110** may vary. Although the upper member **110** illustrated in FIG. **1** includes a total of six protruding portions, other embodiments may include more or less than six protruding portions. For example, in some embodiments, upper member **110** may include a total of five or less protruding portions. In still further embodiments, upper member **110** may include a total of seven or more protruding portions. In some cases, the number of protruding portions substantially corresponds with the number of cleat members.

[0046] In some embodiments, the geometry of the protruding portions may vary. In some embodiments, the protruding portions may be rounded or dome-like in shape. In other embodiments, the protruding portions may be square or rectangular in shape. In other embodiments, the protruding portions may be triangular in shape. Additionally, it will be understood that the protruding portions may be formed in a wide variety of shapes, including but not limited to: hexagonal, cylindrical, conical, conical frustum, circular, square, rectangular, rectangular frustum, trapezoidal, diamond, ovoid, as well as any other shape known to those in the art.

[0047] Although not shown in the embodiment in FIG. **1**, other embodiments may include an indentation along at least a portion of the center of upper member **110**. In some embodiments, the indentation along the center of upper member **110** may be convex with respect to the top surface **119** of upper member **110**. The indentation in the center of upper member **110** may increase the durability of the sole structure **100** and improve its resistance to shock.

[0048] In some embodiments, sole structure **100** may include a chambered member **120**. The chambered member **120** may serve to strengthen the sole structure **100** while at the same time decreasing the overall weight. For example, in some embodiments, the chambered member **120** is made from a different material, and/or different mixture of materials, than the other components in the sole structure **100**. However, in other embodiments, chambered member **120** is made from the same material as the other components, and/or recycled material used to make up other components. Decreasing the weight of sole structure **100** allows the wearer to move more quickly and efficiently, therefore enhancing the wearer's performance.

[0049] Although the chambered member **120** illustrated in FIG. **1** is generally Y-shaped, the overall shape of the chambered member **120** may vary in other embodiments. For example, in some embodiments, the chambered member **120** may form an oval, a rectangle, or any other shape in order to reduce the overall weight of the sole structure **100**.

[0050] In some embodiments, the chambered member **120** may include a plurality of internal chambers. In other words, the volume of the chambered member **120** may include a plurality of cavities that are partitioned off from one another. In one embodiment, as illustrated in FIG. **1**, the volume of the chambered member **120** may include a plurality of hexagon-shaped columns forming a honeycomb pattern. In other embodiments, the volume of the chambered member **120** may include a plurality of any geometrically-shaped columns. In some embodiments, chambered member **120** may include ribs, ridges or a variety of protuberances on the outer surface of chambered member **120**. In other embodiments, chambered member **120** may be solid and/or include ribs or ridges formed on its outer surface.

[0051] In some embodiments, the top surface **122** of chambered member **120** faces the bottom surface **121** of upper member **110**. In some embodiments, the bottom surface **123** of chambered member **120** corresponds to an indentation **131** in an intermediate member **130**, which is discussed in further detail below.

[0052] In some embodiments, sole structure **100** may include an intermediate member **130**. As illustrated in FIG. **1**, intermediate member **130** may include a top surface **161**, a bottom surface **162**, a heel region **163**, a midfoot region **164**, and a forefoot region **165**.

[0053] In some embodiments, intermediate member **130** may include an indentation **131**. In some embodiments, indentation **131** may be concave in relation to the top surface **161** of intermediate member **130**. This allows chambered member **120** to be received within indentation **131** as discussed above. In some embodiments, indentation **131** may be formed so that the top surface **122** of chambered member **120** is flush or level with the top surface **161** of intermediate member **130**. However, in other embodiments, the top surface **122** of chambered member **120** may not be level with the top surface **161** of intermediate member **130**.

[0054] In some embodiments, the shape of indentation **131** may vary. In some embodiments, indentation **131** may be Y-shaped in order to accommodate the shape of the chambered member **120**. However, in other embodiments, indentation **131** may be any other shape that accommodates the chambered member **120**.

[0055] In some embodiments, the location of indentation **131** may vary. In some embodiments, indentation **131** may be located in only a portion of intermediate member **130**. For example, in one embodiment, as shown in FIG. **1**, indentation **131** may be located mainly in the midfoot region **164** of intermediate member **130**. However, in other embodiments, indentation **131** may be located in other regions of intermediate member **130**. In some embodiments, indention **131** may be located in the forefoot region **165** of intermediate member **130**. In another embodiment, indentation **131** may be located in the heel region **163** of intermediate member **130**. In other embodiments, indentation **131** may be located in the forefoot region **165** and midfoot region **164**. In still further embodiments, indentation **131** may be located in the midfoot region **164** and heel region **163**. In still further embodiments, indentation **131** may run the entire length of the shoe and be located in the forefoot region **165**, midfoot region **164** and heel region **163**.

[0056] In some embodiments, upper member **110** may include a plurality of protruding portions associated with the top surface **161** and bottom surface **162** of intermediate member **130**. In some embodiments, the protruding portions include a depression on the top surface of the component, and extend out in a convex manner from the bottom surface of the component. In some embodiments, the protruding portions may be associated with a cleat member.

[0057] Referring to FIG. **1**, intermediate member **130** may include a first protruding portion **133** and a second protruding portion **134** located in the heel region **163**. In some embodiments, intermediate member **130** may include a third protruding portion **135** and a fourth protruding portion **136** located in the forefoot region **165**. As illustrated in FIG. **1**, the fourth protruding portion **136** may include a depression that extends in a concave manner in relation to the top surface **161** of intermediate member **130**, and extends down in a convex manner from the bottom surface **162** of intermediate member **130**. In some embodiments, first protruding portion **133**, second protruding portion **134**, and third protruding portion **135** may be similarly shaped.

[0058] In some embodiments, the geometry of the protruding portions in intermediate member **130** may vary. In some embodiments, the protruding portions may be rounded or dome-like in shape. In other embodiments, the protruding portions may be square or rectangular in shape. In other embodiments, the protruding portions may be triangular in shape. Additionally, it will be understood that the protruding portions may be formed in a wide variety of shapes, including but not limited to: hexagonal, cylindrical, conical, conical frustum, circular, square, rectangular, rectangular frustum, trapezoidal, diamond, ovoid, as well as any other shape known to those in the art.

[0059] In some embodiments, the number of protruding portions in intermediate member **130** may vary. Although the intermediate member **130** illustrated in FIG. **1** includes a total of four protruding portions, other embodiments may include more or less than four protruding portions. For example, in some embodiments, intermediate member **130** may include a total of three or less protruding portions. In still further embodiments, intermediate member **130** may include a total of five or more protruding portions.

[0060] In some embodiments, sole structure **100** may include a bottom member **140**. As illustrated in FIG. **1**, bottom member **140** may include a top surface **171**, a bottom surface **172**, a heel region **147**, a midfoot region **148**, and a forefoot region **149**. In some embodiments, the bottom member **140** may form the outer layer of the bottom surface of the sole structure **100**.

[0061] In some embodiments, bottom member **140** may include a plurality of protruding portions associated with the top surface **171** and bottom surface **172** of bottom member **140**. In some embodiments, the protruding portions include a depression on the top surface of the component, and extend out in a convex manner from the bottom surface of the component. In some embodiments, the protruding portions may be associated with a cleat member.

[0062] Referring to FIG. **1**, bottom member **140** may include a first protruding portion **143** and a second protruding portion **144** located in the heel region **147**. In some embodiments, bottom member **140** may include a third protruding portion **145**, a fourth protruding portion **146**, a fifth protruding portion **141** and a sixth protruding portion **142** located in the forefoot region **149**. As illustrated in FIG. **1**, the sixth protruding portion **142** may include a depression in the top surface **171** of bottom member **140**, and extends out in a convex manner from the bottom surface **172** of bottom member **140**. In some embodiments, first protruding portion **143**, second protruding portion **144**, third protruding portion **145**, fourth protruding portion **146**, and fifth protruding portion **141** may be similarly shaped.

[0063] In some embodiments, the number of protruding portions in bottom member **140** may vary. Although the bottom member **140** illustrated in FIG. **1** includes a total of six protruding portions, other embodiments may include more or less than six protruding portions. For example, in some embodiments, bottom member **140** may include a total of five or less protruding portions. In still further embodiments, bottom member **140** may include a total of seven or more protruding portions.

[0064] In some embodiments, the geometry of the protruding portions in bottom member **140** may vary. In some embodiments, the protruding portions may be rounded or dome-like in shape. In other embodiments, the protruding portions may be square or rectangular in shape. In other embodiments, the protruding portions may be triangular in shape. Additionally, it will be understood that the protruding portions may be formed in a wide variety of shapes, including but not limited to: hexagonal, cylindrical, conical, conical frustum, circular, square, rectangular, rectangular frustum, trapezoidal, diamond, ovoid, as well as any other shape known to those in the art. In some embodiments, the protruding portion can have an elongated and/or rectangular shape that is configured to correspond to the shape of cleat tips **150**.

[0065] In some embodiments, cleat tips **150** may be associated with one or more protruding portions in the bottom surface **172** of bottom member **140**. In some embodiments, first cleat tip **153** may be fixedly attached to the bottom surface **172** associated with the first protruding portion **143** in bottom member **140**. In a similar manner, second cleat tip **154**, third cleat tip **155**, fourth cleat tip **156**, fifth cleat tip **151** and sixth cleat tip **152** may be associated with second protruding portion **144**, third protruding portion **145**, fourth protruding portion **146**, fifth protruding potion **141** and sixth protruding portion **142** respectively.

[0066] In some embodiments, the components shown in FIG. **1** may be joined together to form a sole structure **100**. In some embodiments, the bottom surface **123** of chambered member **120** may be placed in, and attached to, indentation **131** located in the top surface **161** of intermediate member

130. In some embodiments, the bottom surface **121** of upper member **110** may be attached to the top surface **161** of intermediate member **130**. In some embodiments, the top surface **122** of chambered member **120** may also be attached to the bottom surface **121** of upper member **110**. In some embodiments, the bottom surface **162** of intermediate member **130** may be attached to the top surface **171** of bottom member **140**.

[0067] In some embodiments, the protruding portions in each component may be aligned or mated with one another when forming sole structure **100**. In some embodiments, first protruding portion **113** in upper member **110**, first protruding portion **133** in intermediate member **130**, and first protruding portion **143** in bottom member **140** may be mated when forming sole structure **100**. In particular, the convex portion of first protruding portion **113** in upper member **110** may fit into the depression of first protruding portion **133** in intermediate member **130**. Likewise, the convex portion of first protruding portion **133** in intermediate member **130** may fit into the depression of first protruding portion **143** in bottom member **140**. In a similar manner, each of the protruding portions of upper member **110**, intermediate member **130** and bottom member **140** may be joined with corresponding protruding portions on adjacent members. For example, in some embodiments, second protruding portion **114** in upper member **110**, second protruding portion **134** in intermediate member **130**, and second protruding portion **144** in bottom member **140** may be mated when forming sole structure **100**. Also, in some embodiments, third protruding portion **115** in upper member **110**, third protruding portion **135** in intermediate member **130**, and third protruding portion **145** in bottom member **140** may be mated when forming sole structure **100**. In some embodiments, fourth protruding portion **116** in upper member **110**, fourth protruding portion **136** in intermediate member **130**, and fourth protruding portion **146** in bottom member **140** may be mated when forming sole structure **100**. In embodiments where intermediate member **130** does not extend over the full length of sole structure **100**, fifth protruding portion **117** and sixth protruding portion **118** in upper member **110** may be directly mated with fifth protruding portion **141** and sixth protruding portion **142** in bottom member **140**, respectively.

[0068] A sole structure **100** may include provisions for evenly dissipating the forces incurred in the area proximate to each cleat member. Generally, the cleat members are the first component to strike the ground and therefore receive a substantial amount of stress. In order to absorb this stress, some embodiments may include a rigid layer of material that extends into the cleat members as well as a substantial portion of the sole structure **100**. This allows the forces exerted on the cleat members to be evenly distributed over a large surface area of the rigid layer, thereby increasing the overall strength of the sole structure **100**.

[0069] In some embodiments, rigidity of the sole structure **100** may be increased by including a chambered member **120** and an intermediate member **130**. FIG. **2** more clearly shows the relationship between the chambered member **120** and the intermediate member **130**. Indentation **131**, located in the top surface **161** of intermediate member **130** may be formed into a shape that will accommodate the volume of chambered member **120**. In some embodiments, the surface forming indentation **131** may support the bottom surface **123** of chambered member **120**.

[0070] The shape of intermediate member **130** may vary. In some embodiments, as shown in FIG. **2**, intermediate member **130** may include one or more projections. In one embodiment, intermediate member **130** may include one or more rounded projections, or lobes. In another embodiment, intermediate member **130** may include one or more rectangular or square-shaped projections. In still further embodiments, intermediate member **130** may include one or more triangular-shaped projections. In still further embodiments, intermediate member **130** may include any number of other geometrical or non-geometrical shaped projections.

[0071] In some embodiments, intermediate member **130** includes a first projection **137**, a second projection **138** and a third projection **139**. In some embodiments, first projection **137** and second projection **138** may be separated by a gap, while the third projection **139** extends rearwardly. For example, intermediate member **130** may be generally Y-shaped. In other embodiments, intermediate member **130** may be V-shaped, or W-shaped.

[0072] Referring to FIG. **2**, intermediate member **130** may include a number of protruding portions associated with cleat members. In some embodiments, first projection **137** may include fourth protruding portion **136**, while second projection **138** may include third protruding portion **135**. Similarly, third projection **139** may include first protruding portion **133** and second protruding portion **134**. The presence of first protruding portion **133**, second protruding portion **134**, third protruding portion **135** and fourth protruding portion **136** in intermediate member **130** provide for localized stiffening and enable the sole structure **100** to moderate, and more evenly distribute, pressure placed on the cleat members.

[0073] In different embodiments, the material composition of one or more components of sole structure **100** can vary. In some cases, for example, upper member **110**, chambered member **120**, intermediate member **130** and bottom member **140** may be made of a variety of different materials that provide for a lightweight and rigid, yet flexible, sole structure **100**. Some embodiments may also use one or more components, features, systems and/or methods discussed in Auger et al., U.S. Patent Publication Number 2008/0010863, published on Jan. 17, 2008, which is hereby incorporated by reference in its entirety.

[0074] Upper member **110** may be formed from a variety of materials. Generally, the materials used with upper member **110** can be selected to achieve a desired rigidity, flexibility, or desired characteristic for upper member **110**. In some embodiments, upper member **110** may be formed from a weave and/or mesh of glass fibers, fiberglass, fiberglass composite and/or glass-reinforced plastic. In some embodiments, the weave or mesh may be anodized or coated with one or more alloy(s) or metal(s), like silver. In some embodiments, upper member **110** may be formed from carbon, carbon fiber, carbon composite, and/or recycled or reground carbon materials. In some embodiments, upper member **110** may be formed from thermoplastic polyurethanes, recycled thermoplastic polyurethane, and/or composite including thermoplastic polyurethane. In some embodiments, the upper member **110** may be formed from the same material as the upper member **110**. Any combination of materials known to those in the art may form the upper member **110**. In some embodiments, upper member **110** may include one or more regions or portions made from different materials. In some embodiments, upper member **110** may include fibers made from a plurality of materials. For example, in some embodiments, upper member **110** may be made from a variety of composite materials. In some embodiments, upper member **110** may include both carbon and glass fibers. In some embodiments, upper member **110** may include fibers made from a mixture of carbon and one or more other materials. In some embodiments, upper member **110** may include materials made from a mixture of glass and one or more other materials. In other embodiments, upper member **110** may be made from materials that do not include glass fibers or carbon fibers. However, in one embodiment, upper member **110** may be made of fiberglass and/or fiberglass composite.

[0075] In some embodiments, upper member **110** may be made of layers that have varying orientations with respect to one another. In some embodiments, upper member **110** may include fibers that are oriented in an alternating 0/90° orientation and/or an alternating 45°/45° orientation. In some embodiments, upper member **110** may include layers having fibers that are oriented laterally. In some embodiments, upper member **110** may include layers having fibers that are oriented longitudinally. In some embodiments, upper member may include layers having fibers that are oriented side-by-side one another. In other embodiments, upper member **110** may include layers having fibers that are oriented diagonally, or at some angle, with respect to a lateral or longitudinal axis. In some embodiments, each layer in upper member **110** may include one or more portions having fibers that are oriented longitudinally, laterally, side-by-side, and/or diagonally. In some embodiments, each layer of upper member **110** may include one or more portions or regions having different orientations. For example, in one embodiment upper member **110** may include a layer that is diagonally oriented in the forefoot region and longitudinally oriented in the heel region. Other variations in regional orientation are possible. Other embodiments discussed herein in this specification and claims may also include these features of the upper member **110**.

[0076] The chambered member **120** may be formed from a variety of materials. Generally, the materials used with chambered member **120** can be selected to achieve a desired rigidity, flexibility, or desired characteristic for chambered member **120**. In some embodiments, chambered member **120** may be formed from a weave and/or mesh of glass fibers, fiberglass, fiberglass composite and/or glass-reinforced plastic. In some embodiments, the weave or mesh may be anodized or coated with one or more alloy(s) or metal(s), like silver. In some embodiments, chambered member **120** may be formed from carbon, carbon fiber, carbon composite, and/or recycled or reground carbon materials. In some embodiments, chambered member **120** may be formed from thermoplastic polyurethanes, recycled thermoplastic polyurethane, and/or composite including thermoplastic polyurethane. Any combination of materials known to those in the art may form the chambered member **120**. In some embodiments, chambered member **120** may include one or more regions or portions made from different materials. In some embodiments, chambered member **120** may include fibers made from a plurality of materials. For example, in some embodiments, chambered member **120** may be made from a variety of composite materials. In some embodiments, chambered member **120** may include both carbon and glass fibers. In some embodiments, chambered member **120** may include fibers made from a mixture of carbon and one or more other materials. In some embodiments, chambered member **120** may include materials made from a mixture of glass and one or more other materials. In other embodiments, chambered member **120** may be made from materials that do not include glass fibers or carbon fibers. However, in one embodiment, chambered member **120** may be made of a carbon and/or carbon composite.

[0077] In some embodiments, chambered member **120** may be made of layers that have varying orientations with respect to one another. In some embodiments, chambered member **120** may include fibers that are oriented in an alternating 0/90° orientation and/or an alternating 45°/45° orientation. In some embodiments, chambered member **120** may include layers having fibers that are oriented laterally. In some embodiments, chambered member **120** may include layers having fibers that are oriented longitudinally. In some embodiments, chambered member **120** may include layers having fibers that are oriented side-by-side one another. In other embodiments, chambered member **120** may include layers having fibers that are oriented diagonally, or at some angle, with respect to a lateral or longitudinal axis. In some embodiments, each layer in chambered member **120** may include one or more portions having fibers that are oriented longitudinally, laterally, side-by-side, and/or diagonally. In some embodiments, each layer of chambered member **120** may include one or more portions or regions having different orientations. For example, in one embodiment chambered member **120** may include a layer that is diagonally oriented in the midfoot region and longitudinally oriented in the heel region. Other variations in regional orientation are possible. Other embodiments discussed herein in this specification and claims may also include these features of the chambered member **120**.

[0078] The intermediate member **130** may be formed from a variety of materials. Generally, the materials used with intermediate member **130** can be selected to achieve a desired rigidity, flexibility, or desired characteristic for intermediate member **130**. In some embodiments, intermediate member **130** may be formed from a weave and/or mesh of glass fibers, fiberglass, fiberglass composite and/or glass-reinforced plastic. In some embodiments, the weave or mesh may be anodized or coated with one or more alloy(s) or metal(s), like silver. In some embodiments, intermediate member **130** may be formed from carbon, carbon fiber, carbon composite, and/or recycled or reground carbon materials. In some embodiments, intermediate member **130** may be formed from thermoplastic polyurethanes, recycled thermoplastic polyurethane, and/or composite including thermoplastic polyurethane. In some embodiments, the intermediate member **130** may be formed from the same material as the intermediate member **130**. Any combination of materials known to those in the art may form the intermediate member **130**. In some embodiments, intermediate member **130** may include one or more regions or portions made from different materials. In some embodiments, intermediate member **130** may include fibers made from a plurality of materials. For example, in some embodiments, intermediate member **130** may be made from a variety of composite materials. In some embodiments, intermediate member **130** may include both carbon and glass fibers. In some embodiments, intermediate member **130** may include fibers made from a mixture of carbon and one or more other materials. In some embodiments, intermediate member **130** may include materials made from a mixture of glass and one or more other materials. In other embodiments, intermediate member **130** may be made from materials that do not include glass fibers or carbon fibers. However, in one embodiment, intermediate member **130** may be made from carbon fiber.

[0079] In some embodiments, intermediate member **130** may be made of layers that have varying orientations with respect to one another. In some embodiments, intermediate member **130** may include fibers that are oriented in an alternating 0/90° orientation and/or an alternating 45°/45° orientation. In some embodiments, intermediate member **130** may include layers having fibers that are oriented laterally. In some embodiments, intermediate member **130** may include layers having fibers that are oriented longitudinally. In some embodiments, intermediate member **130** may include layers having fibers that are oriented side-by-side one another. In other embodiments, intermediate member **130** may include layers having fibers that are oriented diagonally, or at some angle, with respect to a lateral or longitudinal axis. In some embodiments, each layer in intermediate member **130** may include one or more portions having fibers that are oriented longitudinally, laterally, side-by-side, and/or diagonally. In some embodiments, each layer of intermediate member **130** may include one or more portions or regions having different orientations. For example, in one embodiment intermediate member **130** may include a layer that is diagonally oriented in the forefoot region and longitudinally oriented in the heel region. Other variations in regional orientation are possible. Other embodiments discussed herein in this specification and claims may also include these features of the intermediate member **130**.

[0080] The bottom member **140** may be made from a variety of materials. In some embodiments, bottom member **140** may be formed from a plastic. In another embodiment, any combination of materials known to those in the art may be used to form bottom member **140**. For example, in some embodiments, bottom member **140** may be made from a mixture of the same materials that are used to make upper member **110**, intermediate member **130**, and/or chambered member **120**.

[0081] The upper member **110**, chambered member **120**, intermediate member **130**, and/or bottom member **140** may be formed in any manner. In some embodiments, each component is molded into a preformed shape. In some embodiments, the edges of each component are trimmed using any means known to those in the art, including a water jet.

[0082] The cleat tips **150** may be formed from a variety of materials. Generally, the materials used with cleat tips **150** can be selected to achieve a desired rigidity, flexibility, or desired characteristic for cleat tips **150**. In some embodiments, cleat tips **150** may be formed from a weave and/or mesh of glass fibers, fiberglass, fiberglass composite and/or glass-reinforced plastic. In some embodiments, the weave or mesh may be anodized or coated with one or more alloy(s) or metal(s), like silver. In some embodiments, cleat tips **150** may be formed from carbon, carbon fiber, carbon composite, and/or recycled or reground carbon materials. In some embodiments, cleat tips **150** may be formed from thermoplastic polyurethanes, recycled thermoplastic polyurethane, and/or composite including thermoplastic polyurethane. In some embodiments, the cleat tips **150** are formed from the same material as the chambered member **120**. Any combination of materials known to those in the art may form the cleat tips **150**. In some embodiments, cleat tips **150** may include one or more regions or portions made from different materials. In some embodiments, cleat tips **150** may include fibers made from a plurality of materials. For example, in some embodiments, cleat tips **150** may be made from a variety of composite materials. In some embodiments, cleat tips **150** may include both carbon and glass fibers. In some embodiments, cleat tips **150** may include fibers made from a mixture of carbon and one or more other materials. In some embodiments, cleat tips **150** may include materials made from a mixture of glass and one or more other materials. In other embodiments, cleat tips **150** may be made from materials that do not include glass fibers or carbon fibers. However, in one embodiment cleat tips **150** are made of a carbon and/or carbon composite.

[0083] In some embodiments, cleat tips **150** may be made of layers that have varying orientations with respect to one another. In some embodiments, cleat tips **150** may include fibers that are oriented in an alternating 0/90° orientation and/or an alternating 45°/45° orientation. In some embodiments, cleat tips **150** may include layers having fibers that are oriented laterally. In some embodiments, cleat tips **150** may include layers having fibers that are oriented longitudinally. In some embodiments, cleat tips **150** may include layers having fibers that are oriented side-by-side one another. In other embodiments, cleat tips **150** may include layers having fibers that are oriented diagonally, or at some angle, with respect to a lateral or longitudinal axis. In some embodiments, each layer in cleat tips **150** may include one or more portions having fibers that are oriented longitudinally, laterally, side-by-side, and/or diagonally. In some embodiments, each layer of cleat tips **150** may include one or more portions or regions having different orientations. For example, in one embodiment cleats tips **150** may include a layer that is diagonally oriented in the forefoot region and longitudinally oriented in the heel region. Other variations in regional orientation are possible. Other embodiments discussed herein in this specification and claims may also include these features of the cleat tips **150**.

[0084] The components shown in FIGS. **1** and **2** may be bonded or attached to one another using a variety of methods. In some embodiments, heat pressure may be applied to the components in order bond them together. In some embodiments, thermoplastic polyurethane may be used to bond the components to one another. In another embodiment, any form of adhesive may be used to bond the components together. In still further embodiments, other methods of bonding the components known to those in the art may be used. In some embodiments, upper member **110** and intermediate member **130** are placed in a mold and chambered member **120** is injected into the indentation **131**

[0085] FIG. **3** illustrates the components shown in FIG. **1** after they have been assembled. In other words, the upper member **110**, chambered member **120**, intermediate member **130** are placed on the bottom member **140**, and the cleat tips **150** have been attached. Upper member **110** is transparent in FIG. **3** in order to facilitate an understanding of the components underneath. The sole structure **100** shown in FIG. **3** may include a forefoot region **310**, a midfoot region **312**, and a heel region **314**.

[0086] Referring to FIG. **3**, the location of the projections of intermediate member **130** in relation to other components of the sole structure **100** may vary. In some embodiments, intermediate member **130** may include a first projection **137**, a second projection **138** and a third projection **139**. In some embodiments, at least a portion of the first projection **137** and at least a portion of the second projection **138** may be located in a portion of the forefoot region **310**, while at least a portion of the third projection **139** may be located in at least a portion of the midfoot region **312**. In some embodiments, at least a portion of the first projection **137** and at least a portion of the second projection **138** may be located in at least a portion of the midfoot region **312**, while at least a portion of the third projection **139** may be located in at least a portion of the heel region **314**. In some embodiments, at least a portion of the first projection **137** and at least a portion of the second projection **138** may be located in at least a portion of the forefoot region **310**, while at least a portion of the third projection **139** is located in at least a portion of the heel region **314**.

[0087] In some embodiments, the length of intermediate member **130** may vary. In some embodiments, intermediate member **130** may extend from at least a portion of the heel region **314** to at least a portion of the midfoot region **312**. In other embodiments, intermediate member **130** may extend from at least a portion of the midfoot region **312** to at least a portion of the forefoot region **310**. In other embodiments, intermediate member **130** may extend from at least a portion of the heel region **314**, through the midfoot region **312**, and into at least a portion of the forefoot region **310**. Varying the length of the intermediate member **130** so that it extends over at least a portion of the bottom member **140** may reduce the overall weight of sole structure **100**.

[0088] FIG. **4** illustrates cross-sectional views at various points along the longitudinal length of the sole structure **100** shown in FIGS. **1-3**. The sole structure **100** shown in FIG. **4** includes all the components shown in FIG. **1** after they have been assembled. Upper member **110** is transparent in order to facilitate an understanding of the components underneath. FIG. **4** includes two cross-sectional views in the forefoot region **310**, and two cross-sectional views in the midfoot region **312**.

[0089] Referring to FIG. **4**, a first cross-sectional view **410** in the forefoot region shows only two layers: a portion **412** of upper member **110** and a portion **414** of bottom member **140**. Although first cross-sectional view **410** shows a portion **412** of upper member **110** and a portion **414** of bottom member **140** having approximately the same thickness in this region, the actual thicknesses may vary relative to one another. In some embodiments, a portion **412** of upper member **110** may be made from glass composite and a portion **414** of bottom member **140** may be made from plastic. In such an embodiment, the region shown in cross-sectional view **410** may provide a significant amount of flexibility. In other embodiments, a portion **412** of upper member **110** and a portion **414** of bottom member **140** may be made from any other type of materials.

[0090] A second cross-sectional view **420** shown in FIG. **4** may be located in the forefoot region **310** but more towards the heel region **314** than the first cross-sectional view **410**. In one embodiment, as shown in the second cross-sectional view **420**, a portion **424** of intermediate member **130** is located between a portion **422** of upper member **110** and a portion **426** of bottom member **140**. In some embodiments, a portion **422** of upper member **110** may be made from glass composite, a portion **424** of intermediate member **130** may be made from carbon composite, and a portion **426** of bottom member **140** may be made from plastic. In such an embodiment, the region shown in cross-sectional view **420** may provide rigidity from the carbon composite portion **424** of intermediate member **130**, in addition to flexibility from the glass composite portion **422** of upper member **110**. In other embodiments, portion **422** of upper member **110**, portion **424** of intermediate member **130**, and portion **426** of bottom member **140** may be made from any other type of materials. It should be noted that the thicknesses of portion **422** of upper member **110**, portion **424** of intermediate member **130**, and portion **426** of bottom member **140** may vary in relation to one another.

[0091] A third cross-sectional view **430** shown in FIG. **4** may be located in the midfoot region **312**. In one embodiment, as shown in third cross-sectional view **430**, portion **434** of intermediate member **130** may be located between portion **432** of upper member **110** and portion **436** of bottom member **140**. In one embodiment, as shown in third cross-sectional view **430**, portion **433** of chambered member **120** may be located between portion **432** of upper member **110** and portion **434** of intermediate member **130**. In some embodiments, chambered portion **433** of chambered member **120** may have a Y-shape. In some embodiments, portion **432** of upper member **110** may be made from glass composite, portion **434** of intermediate member **130** may be made from carbon composite, and portion **436** of bottom member **140** may be made from plastic. In such an embodiment, portion **432** of upper member **110** may provide flexibility in this region, while portion **434** of intermediate member **130** and portion **433** of chambered member **120** may provide rigidity in this region. In some embodiments, portion **433** of chambered member **120** may have a honeycomb volume and may be made from carbon or carbon composite. In such an embodiment, chambered portion **433** of member **120** may provide rigidity to this region, while at the same time reducing the overall weight of the sole structure **100**. In other embodiments, portion **432** of upper member **110**, portion **433** of chambered member **120**, portion **434** of intermediate member **130**, and portion **436** of bottom member **140** may be made from any other type of materials. It should be noted that in some embodiments, the thicknesses of portion **432** of upper member **110**, portion **433** of chambered member **120**, portion **434** of intermediate member **130**, and portion **436** of bottom member **140**, may vary in relation to one another.

[0092] A fourth cross-sectional view **440** shown in FIG. **4** is located in the midfoot region **312** but more towards the heel region **314** than the third cross-sectional view **430**. In one embodiment, as shown in fourth cross-sectional view **440**, portion **444** of intermediate member **130** may be located between portion **442** of upper member **110** and portion **446** of bottom member **140**. In some embodiments, portion **443** of chambered member **120** may be located between portion **442** of upper member **110** and portion **444** of intermediate member **130**. In one embodiment, chambered member **120** may have a Y-shape. As can be seen in fourth cross-sectional view **440**, portion **443** may form the stem of the Y-shaped chambered member **120**. Portion **443** of chambered member **120** may be located between portion **442** of upper member **110** and portion **444** of intermediate member **130**. In some embodiments, portion **442** of upper member **110** may be made from glass composite, portion **444** of intermediate member **130** may be made from carbon composite, and portion **446** of bottom member **140** may be made from plastic. In such an embodiment, portion **442** of upper member **110** may provide flexibility in this region, while portion **444** of intermediate member **130** and portion **443** of chambered member **120** may provide rigidity in this region. In some embodiments, portion **443** of chambered member **120** may have a honeycomb volume and may be made from carbon or carbon composite. In such an embodiment, portion **443** of chambered member **120** may provide rigidity to this region, while at the same time reducing the overall weight of the sole structure **100**. In other embodiments, portion **442** of upper member **110**, portion **443** of chambered member **120**, portion **444** of intermediate member **130**, and portion **446** of bottom member **140** may be made from any other type of materials. It should be noted that the thicknesses of portion **442** of upper member **110**, portion **443** of chambered member **120**, portion **444** of intermediate member **130**, and portion **446** of bottom member **140**, as shown in fourth cross-sectional view **440**, may vary in relation to one another.

[0093] In some embodiments, provisions may be included for providing different zones of flexibility along the longitudinal length of the sole structure **100**. Different zones of flexibility can be created by varying the material, thickness, and/or longitudinal length of the components making up the sole structure **100**. In some embodiments, the zones of flexibility can be adjusted in order to adapt to the shape of each wearer's foot. In some embodiments, the zones of flexibility can be adjusted in order to adapt to each wearer's running style. In some embodiments, the zones of flexibility can be adjusted in order to adapt to the type of sport and/or activity in which the wearer will be involved.

[0094] FIG. **5** illustrates a schematic cross-section of the embodiment of the sole structure **100** taken along line **5-5** in FIG. **3**. FIG. **5** describes one embodiment relating to different zones of flexibility along the longitudinal length of the sole structure **100** shown in FIGS. **1-4**. FIG. **5** shows four zones of flexibility along the longitudinal length of the shoe. In some embodiments, zone D may be associated with a heel region **314** of the sole structure **100**. In some embodiments, zone C may be associated with a midsole region **312** of the sole structure **100**. In some embodiments, zone A and B may be associated with a forefoot region **310** of the sole structure **100**. In other embodiments, the zones of flexibility may or may not be associated with the heel region, midsole region, and/or forefoot region of the sole structure **100**. Although FIG. **5** shows four zones, other embodiments may include more or less than four zones of flexibility. In other embodiments, upper member **110**, intermediate member **130** and bottom member **140** may be made from any other type of materials.

[0095] Referring to FIG. **5**, the four zones are generally separated by boundary X, boundary Y and boundary Z. In particular, boundary X may generally separate zone D and zone C. Likewise, boundary Y may generally separate zone C and zone B. Furthermore, boundary Z may generally separate zone B and zone A.

[0096] In some embodiments, the zones of flexibility may be controlled in part by the longitudinal length of each component and/or the material making up each component. In the embodiment shown in FIG. **5**, upper member **110** may extend from zone D to zone A. In some embodiments, upper member **110** may be made from a glass composite. The glass composite upper member **110** may provide for flexibility throughout the longitudinal length of the sole structure **100** from zone D to zone A. For example, upper member **110** may provide for flexibility to the cleat member associated with first protruding portion **113** in heel region **314**. As a further example, upper member **110** may provide for flexibility in the midfoot region **312**. As a further example, upper member **110** may provide for flexibility to the cleat members associated with third protruding portion **115** and fifth protruding portion **117** in the forefoot region **310**.

[0097] Also shown in FIG. **5** is a chambered member **120** extending through zone C. In some embodiments, the chambered member **120** may be made from carbon or carbon composite. The carbon composite chambered member **120** may provide rigidity, or stiffness, in the midfoot region **312** of sole structure **100**. In some embodiments, the volume of chambered member **120** forms a honeycomb, which may reduce the overall weight of sole structure **100** while at the same time providing rigidity, or stiffness.

[0098] Also shown in FIG. **5** is an intermediate member **130** extending from zone D to zone B. In some embodiments, the intermediate member **130** may be made from carbon or carbon composite. The carbon composite intermediate member **130** may provide for additional rigidity, or stiffness, from the heel region **314** into a portion of the forefoot region **310**. For example, carbon composite intermediate member **130** may provide for rigidity in the cleat member associated with first protruding portion **133** in the heel region **314**. As a further example, carbon composite intermediate member **130** may provide for rigidity in the midfoot region **312**. As a further example, carbon composite intermediate member **130** may provide for rigidity in the cleat member associated with third protruding portion **135** in zone B. The carbon composite intermediate member **130** is capable of absorbing impact pressure felt in the cleat members associated with first protruding portion **133** and third protruding portion **135**. Since the carbon composite intermediate member **130** does not extend past boundary Z into the zone A, the sole structure **100** in FIG. **5** may be more flexible in zone A than in zone B. Since the carbon composite intermediate member **130** is not located in the more flexible zone A, carbon composite intermediate member **130** is less likely to become denatured due to excessive bending and flexing that may occur in zone A.

[0099] Also shown in FIG. **5** is a bottom member **140** extending from zone D to zone A. In some embodiments, the bottom member **140** may be made from plastic. In other embodiments, the bottom member **140** may be made from any material known to those in the art would understand to make up an article of footwear.

[0100] Some embodiments may include provisions for varying the material composition of each component along the longitudinal length of the sole structure **100** in order to achieve the desired flexibility and/or rigidity in each zone. For example, in some embodiments, upper member **110** may have a different material composition in one zone than in the remaining zones. In other embodiments, upper member **110** may have a different material composition in two or more zones than in the remaining zone(s). In some embodiments, intermediate member **130** may have a different material composition in one zone than in the remaining zones. In other embodiments, intermediate member **130** may have a different material composition in two or more zones than in the remaining zone(s). In some embodiments, bottom member **140** may have a different material composition in one zone than in the remaining zones. In some embodiments, bottom member **140** may have a different material composition in two or more zones than the remaining zone(s). In some embodiments, each component may have a varying composition within the same zone of flexibility.

[0101] The thickness of each component in sole structure **100** may vary. As shown in FIG. **5**, upper member **110** may have a thickness T**1**, intermediate member **130** may have a thickness T**2**, bottom member **140** may have a thickness T**3**, and chambered member **120** may have thickness T**4**. In some embodiments, thickness T**1**, thickness T**2** and thickness T**3** may be equal. In other embodiments, thickness T**1** may be equal to thickness T**2**, while thickness T**2** is less than or greater than thickness T3. In other embodiments, thickness T1 may be equal to thickness T3, while thickness T3 is less than or greater than thickness T2. In other embodiments, thickness T2 may be equal to thickness T3, while thickness T3 is less than or greater than thickness T1. In other embodiments, thickness T1, thickness T2 and thickness T3 may all have different values.

[0102] A sole structure **100** may include provisions for adjusting the flexibility and/or rigidity of the sole structure **100** by varying the thickness of each component in throughout each zone of flexibility. In some embodiments, each component may have a different thickness in each zone of flexibility. In some embodiments, each component may have the same thickness throughout one or more zones of flexibility. In other embodiments, the thickness of each component may vary in specific zones of flexibility in order to increase or decrease the rigidity and/or flexibility in that particular zone. For example, in some embodiments where intermediate member **130** is made from carbon composite and a more flexible zone B is desired, thickness T2 of intermediate member **130** may decrease in zone B to be less than the thickness in zone C and/or D. As a further example, in embodiments where intermediate member **130** is made from carbon composite and a more rigid zone B is desired, thickness T2 of intermediate member **130** may increase in zone B to be more than the thickness in zone C and/or zone D. In other embodiments, the thickness T2 of intermediate member **130** may vary throughout the longitudinal length of the sole structure **100** in order to achieve the desired flexibility and/or rigidity in each zone of flexibility.

[0103] In some embodiments, the thickness T1 of upper member **110** may vary throughout the longitudinal length of the sole structure **100** in order to achieve the desired flexibility and/or rigidity in each zone of flexibility. For example, in some embodiments where the upper member **110** is made from glass composite and a more flexible zone B is desired, thickness T1 of upper member **110** may be increased in zone B to be more than the thickness in zone C and/or D. As a further example, in some embodiments, where the upper member **110** is made from glass composite and a less flexible zone B is desired, thickness T1 of upper member **110** is decreased in zone B to be less than the thickness in zone C and/or D.

[0104] In some embodiments, the thickness T3 of bottom member **140** may vary throughout the longitudinal length of the sole structure **100** in order to achieve the desired flexibility and/or rigidity in each zone of flexibility. In some embodiments, the thickness T4 of chambered member **120** may vary throughout the longitudinal length of the sole structure **100** in order to achieve the desired flexibility and/or rigidity.

[0105] FIG. **6** shows the sole structure **100** in FIGS. **1-5** while the wearer is running on ground **510**. As illustrated in FIG. **6**, the sole structure **100** may flex or bend at boundary Z, or anywhere in zone A. The flexibility along boundary Z, as well as in zone A, allows the toes of the wearer to bend as needed during use.

[0106] In some embodiments, provisions can be made to prevent denaturing of the intermediate member **130**. Denaturing of the intermediate member **130** may occur if the intermediate member **130** is exposed to excessive bending or other forces. In some embodiments, the shape of intermediate member **130** may prevent the denaturing of the material making up intermediate member **130**. As can be seen in FIG. **6**, only a small portion of first projection **137** and second projection **138** are located on boundary Z, or zone A. In contrast, a curved portion **515** is located some distance away from boundary Z as well as zone A. The shape of intermediate member **130** acts to prevent denaturing of the material making up intermediate member **130**, because curved portion **515** is not exposed to the bending forces present along boundary Z or in zone A. Although the embodiment in FIG. **6** shows a curved portion **515**, other shapes are also possible. In some embodiments, intermediate member **130** may form a triangular or rectangular portion instead of a curved portion **515**. In other embodiments, intermediate member **130** may form any other shape instead of curved portion **515**.

[0107] In some embodiments, the organization of the components may vary in order to adjust a sole structure **100** to the proper stiffness and/or rigidity. FIG. **7**, for example, illustrates one embodiment of a sole structure **700** which may provide more rigidity than the embodiment shown in FIGS. **1-6**. The embodiment shown in FIG. **7** includes an upper member **710**, a chambered member **720**, and an intermediate member **730**. The embodiment shown in FIG. **7** is similar to the embodiments discussed in FIGS. **1-6**, except that the chambered member **720** is located within an indentation **713** in the bottom surface **712** of the upper member **710**. Generally, locating the chambered member **720** inside an indentation **713** in the bottom surface **712** of upper member **710** increases the overall rigidity of the sole structure **700** in the region of the chambered member **720**. In some embodiments, the chambered member **720** may be substantially flat and have a substantially constant thickness throughout. Although FIG. **7** shows the chambered member **720** positioned in an indentation **713** in the bottom surface **712** of upper member **710**, the current embodiments are not so limited. For example, in some embodiments only a portion of chambered member **720** may be located within indentation **713** in upper member **710**. In some embodiments, only a portion of chambered member **720** may be located within an indentation (not shown in FIG. **7**) in the top surface **731** of intermediate member **730**. In other embodiments, a portion of chambered member **720** may be located within indentation **713** in upper member **710**, while another portion of chambered member **720** may be located in an indentation (not shown in FIG. **7**) in the top surface **731** of intermediate member **730**.

[0108] The properties and relationships among the various components described in FIGS. **1-6** may also apply to the embodiment shown in FIG. **7**. For example, the embodiments described in FIG. **7** may also include a bottom member **140** and cleat tips **150** as discussed in FIGS. **1-6**, even though these components are not described in FIG. **7**. In some embodiments, upper member **710**, chambered member **720** and intermediate member **730** may be made from the same materials, and methods, as previously discussed in FIGS. **1** and **2** for upper member **110**, chambered member **120** and intermediate member **130**, respectively.

[0109] The relationship among the components described in FIG. **7** may be similar to the relationships of the components described in FIGS. **1-6**. In some embodiments, upper member **710** may have a top surface **711** and a bottom surface **712**. In some embodiments, the bottom surface **712** of upper member **710** may have an indentation **713** for receiving the chambered member **720**. As illustrated in FIG. **7**, indentation **713** in the bottom surface **712** of upper member **710** may be adapted to receive the top surface **722** of chambered member **720**. In some embodiments, the entire volume of the chambered member **720** may be located in the indentation **713**, so that the bottom surface **723** of chambered member **720** is level with the bottom surface **712** of upper member **710**. In some embodiments, the bottom surface **723** of chambered member **720**, as well as the bottom surface **712** of upper member **710**, may be attached to the top surface **731** of intermediate member **730**.

[0110] The materials making up the components shown in FIG. **7** may vary in order to provide for rigidity in some areas, while providing for flexibility in other areas. In some embodiments, both upper member **710** and intermediate member **730** may be made from carbon or carbon composite. In some embodiments, both upper member **710** and intermediate member **730** may be made from glass or glass composite. In some embodiments, upper member **710** may be made from glass or glass composite and intermediate member **730** may be made from carbon or carbon composite. In other embodiments, upper member **710** may be made form carbon or carbon composite and intermediate member **730** may be made from glass or glass composite. The materials making up the upper member **710** and intermediate member **730** may be any of the materials previously discussed for upper member **110** and intermediate member **130**, respectively, in FIGS. **1-6**.

[0111] The structure and make up of the chambered member **720** may vary. In some embodiments, chambered member **720** may form a honeycomb volume. In some embodiments, carbon chambered member **720** having a honeycomb volume may form a lightweight yet rigid layer in sole structure **700**. In some embodiments, chambered member **720** having a honeycomb volume may add enough rigidity such that the thickness of other components may be reduced. By reducing the thickness of other solid components, the weight of the overall sole structure **700** is reduced. In some embodiments, chambered member **720** may be made from any of the materials previously discussed for chambered member **120** in FIGS. **1-6**.

[0112] Components from different embodiments may be combined with, or replace, components in other embodiments in order to adjust for the desired rigidity and/or flexibility of the sole structure. For example, in some embodiments, upper member **710** described in FIG. **7** may be used in place of upper member **110** described in FIGS. **1-6**. In such an embodiment, bottom surface **123** of chambered member **120** would be positioned in indentation **131** in the top surface **161** of the intermediate member **130**, while the top surface **122** of chambered member **120** would be positioned in indentation **713** on the bottom surface **712** of upper member **710**.

[0113] In some embodiments, the organization of the components may further vary in order to adjust for the proper stiffness and/or rigidity. FIG. **8**, for example, illustrates another embodiment of a sole structure **800**. The embodiment shown in FIG. **8** is similar to the embodiments discussed in FIGS. **1-6**, except that upper member **810** extends over only a portion of the intermediate member **830** in the forefoot area **840**. Generally, orienting the components in such a manner may provide for increased rigidity closer to the wearer's foot.

[0114] The properties and relationships among the various components described in FIGS. **1-6** also apply to the embodiment shown in FIG. **8**. For example, the embodiments described in FIG. **8** may also include a bottom member **140** and cleat tips **150** as discussed in FIGS. **1-6**, even though these components are not described in FIG. **8**. The embodiments described in FIG. **8** include an upper member **810**, a chambered member **820**, and an intermediate member **830**. In some embodiments, upper member **810**, chambered member **820** and intermediate member **830** may be made from the same materials, and methods, as previously discussed in FIGS. **1** and **2** for upper member **110**, chambered member **120** and intermediate member **130**, respectively.

[0115] The components in FIG. **8** may have similar relationships to one another as the components described in FIGS. **1-7**. In some embodiments, intermediate member **830** may have a top surface **833** and a bottom surface **832**. In some embodiments, the top surface **833** of intermediate member **830** may have an indentation **831** for receiving the chambered member **820**. As illustrated in FIG. **8**, indentation **831** in the top surface **833** of intermediate member **830** may be adapted to receive the bottom surface **822** of chambered member **820**. In some embodiments, the entire volume of the chambered member **820** may be located in the indentation **831**, so that the top surface **821** of chambered member **820** is level with the top surface **833** of intermediate member **830**. In some embodiments, the top surface **821** of chambered member **820**, as well as the top surface **823** of intermediate member **830**, may be attached to the bottom surface **812** of upper member **810**.

[0116] In some embodiments, the components shown in FIG. **8** may be assembled in a similar manner as the components described in FIGS. **1-6**. As can be seen in FIG. **8**, when bottom surface **812** of upper member **810** is attached to top surface **833** of intermediate member **830**, upper member **810** only covers a portion of the intermediate member **830** in the forefoot region **846**. In some embodiments, first protruding portion **815** in upper member **810** and first protruding portion **836** in intermediate member **830** may be mated when forming sole structure **800**. Likewise, in some embodiments, second protruding portion **816** in upper member **810** and second protruding portion **837** in intermediate member **830** may be mated when forming sole structure **800**. In some embodiments, third protruding portion **813** in upper member **810** and third protruding portion **834** in intermediate member **830** may be mated when forming sole structure **800**. In some embodiments, fourth protruding portion **814** in upper member **810** and fourth protruding portion **835** in intermediate member **830** may be mated when forming sole structure **800**. Note however, in contrast to the previous embodiments, fifth protruding portion **838** and sixth protruding portion **839** in intermediate member **830** may not be mated with any depressions in upper member **810**.

[0117] The materials making up the components shown in FIG. **8** may vary in order to provide for rigidity in some areas, while providing for flexibility in other areas. In some embodiments, both upper member **810** and intermediate member **830** may be made from carbon or carbon composite. In some embodiments, both upper member **810** and intermediate member **830** may be made from glass or glass composite. In some embodiments, upper member **810** may be made from glass or glass composite and intermediate member **830** may be made from carbon or carbon composite. In other embodiments, upper member **810** may be made form carbon or carbon composite and intermediate member **830** may be made from glass or glass composite. The materials making up the upper member **810** and intermediate member **830** may be any of the materials previously discussed for upper member **110** and intermediate member **130**, respectively, in FIGS. **1-6**.

[0118] The structure and make up of the chambered member **820** may vary. In some embodiments, chambered member **820** may form a honeycomb volume. In some embodiments, carbon chambered member **820** having a honeycomb volume may form a lightweight yet rigid layer in sole structure **800**. In some embodiments, chambered member **820** having a honeycomb volume may add enough rigidity such that the thickness of other components may be reduced. By reducing the thickness of other solid components, the weight of the overall sole structure **800** is reduced. In some embodiments, chambered member **820** may be made from any of the materials previously discussed for chambered member **120** in FIGS. **1-6**.

[0119] In some embodiments, intermediate member **830** may be made from glass composite, chambered member **820** may be made from carbon or carbon composite, and upper member **810** may be made from carbon or carbon composite. In some embodiments, indentation **831** in top surface **833** of intermediate member **830**, as well as chambered member **820**, may be Y-shaped. In some embodiments, chambered member **820** may have a honeycomb volume. In such an embodiment, the rigidity of the sole structure **800** is increased in the area of the chambered member **820** since the flexible glass composite is being replaced by a rigid carbon or carbon composite. In addition, a more rigid carbon composite upper member **810** is located near the wearer's foot than the embodiments illustrated in FIGS. **1-6**.

[0120] In some embodiments, the organization of the components may further vary in order to adjust a sole structure **900** to the proper stiffness and/or rigidity. FIG. **9**, for example, illustrates another embodiment of a sole structure **900**. The embodiment shown in FIG. **9** includes an upper member **910**, a chambered member **920**, and an intermediate member **930**. The embodiment shown in FIG. **9** is similar to the embodiments discussed in FIG. **8**, except that the chambered member **920** is located within an indentation **913** in the bottom surface **912** of the upper member **910**. Generally, locating the chambered member **920** inside an indentation **913** in the bottom surface **912** of upper member **910** decreases the overall weight of the sole structure **900** compared to the sole structure **800** described in FIG. **8**.

[0121] The properties and relationships among the various components described in FIGS. **1-6** also apply to the embodiment shown in FIG. **9**. For example, the embodiments described in FIG. **9** may also include a bottom member **140** and cleat tips **150** as discussed in FIGS. **1-6**, even though these components are not described in FIG. **9**. The embodiments described in FIG. **9** include an upper member **910**, a chambered member **920** and an intermediate member **930**. In some embodiments, upper member **910**, chambered member **920** and intermediate member **930** may be made from the same materials, and methods, as previously discussed in FIGS. **1-6** for upper member **110**, chambered member **120** and intermediate member **130**, respectively.

[0122] The components in FIG. **9** may have similar relationships to one another as the components described in FIGS. **1-6**. In some embodiments, upper member **910** may have a top surface **911** and a bottom surface **912**. In some embodiments, the bottom surface **912** of upper member **910** may have an indentation **913** for receiving the chambered member **920**. As illustrated in FIG. **9**, indentation **913** in the bottom surface **912** of upper member **910** may be adapted to receive the top surface **921** of chambered member **920**. In some embodiments, the entire volume of the chambered member **920** may be located in the indentation **913**, so that the bottom surface **922** of chambered member **920** is level with the bottom surface **912** of upper member **910**. In some embodiments, the bottom surface **922** of chambered member **920**, as well as the bottom surface **912** of upper member **910**, may be attached to the top surface **931** of intermediate member **930**. In some embodiments, the chambered member **920** may be substantially flat and have a substantially constant thickness throughout. Although FIG. **9** shows the chambered member **920** positioned in an indentation **913** in the bottom surface **912** of upper member **910**, the current embodiments are not so limited. For example, in some embodiments only a portion of chambered member **920** may be located within indentation **913** in upper member **910**. In some embodiments, only a portion of chambered member **920** may be located within an indentation (not shown in FIG. **9**) in the top surface **931** of intermediate member **930**. In other embodiments, a portion of chambered member **920** may be located within indentation **913** in upper member **910**, while another portion of chambered member **920** may be located in an indentation (not shown in FIG. **9**) in the top surface **931** of intermediate member **930**.

[0123] The materials making up the components shown in FIG. **9** may vary in order to provide for rigidity in some areas, while providing for flexibility in other areas. In some embodiments, both upper member **910** and intermediate member **930** may be made from carbon or carbon composite. In some embodiments, both upper member **910** and intermediate member **930** may be made from glass or glass composite. In some embodiments, upper member **910** may be made from glass or glass composite and intermediate member **930** may be made from carbon or carbon composite. In other embodiments, upper member **910** may be made form carbon or carbon composite and intermediate member **930** may be made from glass or glass composite. The materials making up the upper member **910** and intermediate member **930** may be any of the materials previously discussed for upper member **110** and intermediate member **130**, respectively, in FIGS. **1-6**.

[0124] The structure and make up of the chambered member **920** may vary. In some embodiments, chambered member **920** may form a honeycomb volume. In some embodiments, carbon chambered member **920** having a honeycomb volume may form a lightweight yet rigid layer in sole structure **900**. In some embodiments, chambered member **920** having a honeycomb volume may add enough rigidity such that the thickness of other components may be reduced. By reducing the thickness of other solid components, the weight of the overall sole structure **900** is reduced. In some embodiments, chambered member **920** may be made from any of the materials previously discussed for chambered member **120** in FIGS. **1-6**.

[0125] Components from different embodiments may be combined with, or replace, components in other embodiments in order to vary the overall rigidity and/or flexibility of the sole structure. For example, in some embodiments, upper member **910** described in FIG. **9** may be used in place of upper member **810** described in FIG. **8**. In such an embodiment, bottom surface **822** of chambered member **820** would be positioned in indentation **831** in the top surface **833** of the intermediate member **830**, while the top surface **821** of chambered member **820** would be positioned in indentation **913** on the bottom surface **912** of upper member **910**.

[0126] In another embodiment, a sole structure **1000** may include provisions for optimizing the overall weight for varying amounts of desired rigidity. For example, FIG. **10** shows a sole structure **1000** that includes a layer having a honeycomb volume. The embodiment shown in FIG. **10** is similar to the embodiments discussed in FIGS. **1-6**, except that the embodiment in FIG. **10** includes a honeycomb layer that is not located within an indentation of another component. Instead, the honeycomb structure forms an additional layer in order to provide lightweight rigidity to the sole structure **1000**.

[0127] The properties and relationships among the various components described in FIGS. **1-6** also apply to the embodiment shown in FIG. **10**. For example, the embodiments described in FIG. **10** may also include a bottom member **140** and cleat tips **150** as discussed in FIGS. **1-6**, even though these components are not described in FIG. **10**. The embodiments described in FIG. **10** include an upper member **1010**, a chambered member **1020** and an intermediate member **1030**.

[0128] The size, shape and thickness of chambered member **1020** may vary. In some embodiments, as shown in FIG. **10**, the chambered member **1020** may have a shape and/or size similar to the shape and/or size of the intermediate member **1030**. In other embodiments, the chambered member **1020** may be smaller in size than the intermediate member **1030**. In other embodiments, the chambered member **1020** may be larger in size than the intermediate member **1030**. In some embodiments, the chambered member may be similar in shape and/or size to the upper member **1010**. In some embodiments, the chambered member **1020** may be substantially flat and may have a substantially constant thickness throughout. However, in other embodiments, the chambered member **1020** may have some portions that have a greater thickness than other portions.

[0129] The components in FIG. **10** may have similar relationships to one another as the components described in FIGS. **1-6**. In some embodiments, the bottom surface **1021** of upper member **1010** may attach to the top surface **1022** of chambered member **1020**. In some embodiments, the bottom surface **1023** of chambered member **1020** may attach to the top surface **1031** of intermediate member **1030**. In some embodiments, bottom surface **1032** of intermediate member **1030** may attach to a bottom member (not shown in FIG. **10**). In some embodiments, upper member **1010**, chambered member **1020** and intermediate member **1030** may be made from the same materials, and methods, as previously discussed in FIGS. **1** and **2** for upper member **110**, chambered member **120** and intermediate member **130**, respectively.

[0130] In some embodiments, the size and shape of chambered member **1020** may vary in order to achieve the desired rigidity and/or flexibility. In one embodiment, as shown in FIG. **10**, chambered member **1020** may be associated mainly with the midfoot region **1024** of upper member **1010**. In other embodiments, chambered member **1020** may be associated with the heel region **1012**, midfoot region **1024**, and/or forefoot region **1011** of upper member **1010**. In some embodiments, chambered member **1020** may be associated with the heel region **1012** and midfoot region **1024** of upper member **1010**. In some embodiments, chambered member **1020** may be associated with the midfoot region **1024** and forefoot region **1011** of upper member **1010**. In some embodiments, chambered member **1020** may be associated with the heel region **1012** and forefoot region **1011** of upper member **1010**.

[0131] In some embodiments, chambered member **1020** may be associated with one or more cleat members. For example, in some embodiments chambered member **1020** may include protruding portions (not shown in FIG. **10**) corresponding to one or more cleat members. In some embodiments, chambered member **1020** may extend between first protruding portion **1013** in upper member **1010** and first protruding portion **1033** in intermediate member **1030**. In some embodiments, chambered member **1020** may extend between second protruding portion **1014** in upper member **1010** and second protruding portion **1034** in intermediate member **1030**. In some embodiments, chambered member **1020** may extend between third protruding portion **1015** in upper member **1010** and third protruding portion **1035** in intermediate member **1030**. In some embodiments, chambered member **1020** may extend between fourth protruding portion **1016** in upper member **1010** and fourth protruding portion **1036** in intermediate member **1030**. In some embodiments, chambered member may be associated with fifth protruding portion **1017** and/or sixth protruding portion **1018** in upper member **1010**. In addition, chambered member **1020** may be associated with any cleat member in any embodiment discussed herein. Also, chambered member **1020** may form a layer between any two components in any embodiment discussed herein.

[0132] The materials making up the components shown in FIG. **10** may vary in order to provide for rigidity in some areas, while providing for flexibility in other areas. In some embodiments, both upper member **1010** and intermediate member **1030** may be made from carbon or carbon composite. In some embodiments, both upper member **1010** and intermediate member **1030** may be made from glass or glass composite. In some embodiments, upper member **1010** may be made from glass or glass composite and intermediate member **1030** may be made from carbon or carbon composite. In other embodiments, upper member **1010** may be made form carbon or carbon composite and intermediate member **1030** may be made from glass or glass composite. The materials making up the upper member **1010** and intermediate member **1030** may be any of the materials previously discussed for upper member **110** and intermediate member **130**, respectively, in FIGS. **1-6**.

[0133] The structure and make up of the chambered member **1020** may vary. In some embodiments, chambered member **1020** may form a honeycomb volume. In some embodiments, carbon chambered member **1020** having a honeycomb volume may form a lightweight yet rigid layer in sole structure **1000**. In some embodiments, chambered member **1020** having a honeycomb volume may add enough rigidity such that the thickness of other components may be reduced. By reducing the thickness of other solid components, the weight of the overall sole structure **1000** is reduced. In some embodiments, chambered member **1020** may be made from any of the materials previously discussed for chambered member **120** in FIGS. **1-6**.

[0134] The organization of the components shown in FIG. **10** may vary in order to achieve the desired flexibility and/or rigidity. FIG. **10** shows the upper member **1010** located above chambered member **1020** with intermediate member **1030** located below chambered member **1020**. However, other embodiments may include upper member **1010** located below chambered member **1020** with intermediate member **1030** located above chambered member **1020**. In other embodiments, upper member **1010**, chambered member **1020** and bottom member **1030** may be further varied in order to achieve the desired rigidity and/or flexibility.

[0135] In some embodiments, provisions may be made for reducing the weight of the sole structure while adjusting the rigidity and/or flexibility. For example, some embodiments may include indentations in more than one component. The indentations of the components may then be aligned and mated during assembly while a chambered member is located in the uppermost member. Since the material making up the chambered member may be less dense than the other components, displacing the material making up the other components with the volume of the chambered member reduces the overall weight of the sole structure. Additionally, the chambered member may increase the overall rigidity of the sole structure in the region where the indentations are located.

[0136] Referring to FIG. **11**, one embodiment may include a chambered member **1170**, an upper member **1180**, and an intermediate member **1190**. FIG. **11** shows an indentation **1183** in upper member **1180**, and an indentation **1193** in intermediate member **1190**. During assembly, the top surface **1194** of indentation **1193**, located on the top surface **1191** of intermediate member **1190**, may be mated with the bottom surface **1185** of indentation **1185**, located on the bottom surface **1182** of upper member **1180**. Bottom surface **1172** of chambered member **1170** may be located in the top surface **1184** of indentation **1183**, located on the top surface **1181** of upper member **1183**. In some embodiments, top surface **1171** of chambered member **1170** may be flush with the top surface **1181** of upper member **1180**. In other embodiments, top surface **1171** of chambered member **1170** may not be flush with the top surface **1181** of upper member **1180**.

[0137] The properties and relationships among the various components described in FIGS. **1-6** also apply to the embodiments described in FIG. **11**. For example, the embodiments described in FIG. **11** may also include a bottom member **140** and cleat tips **150** as discussed in FIGS. **1-6**, even though these components are not described in FIG. **11**. In some embodiments, upper member **1180**, chambered member **1170** and intermediate member **1190** may be made from the same materials, and methods, as previously discussed in FIGS. **1** and **2** for upper member **110**, chambered member **120** and intermediate member **130**, respectively.

[0138] The materials making up the components shown in FIG. **11** may vary in order to provide for rigidity in some areas, while providing for flexibility in other areas. In some embodiments, both upper member **1110** and intermediate member **1130** may be made from carbon or carbon composite. In some embodiments, both upper member **1110** and intermediate member **1130** may be made from glass or glass composite. In some embodiments, upper member **1110** may be made from glass or glass composite and intermediate member **1130** may be made from carbon or carbon composite. In other embodiments, upper member **1110** may be made form carbon or carbon composite and intermediate member **1130** may be made from glass or glass composite. The materials making up the upper member **910** and intermediate member **1130** may be any of the materials previously discussed for upper member **110** and intermediate member **130**, respectively, in FIGS. **1-6**.

[0139] The structure and make up of the chambered member **1120** may vary. In some embodiments, chambered member **1120** may form a honeycomb volume. In some embodiments, carbon chambered member **1120** having a honeycomb volume may form a lightweight yet rigid layer in sole structure **1100**. In some embodiments, chambered member **1120** having a honeycomb volume may add enough rigidity such that the thickness of other components may be reduced. By reducing the thickness of other solid components, the weight of the overall sole structure **1100** is reduced. In some embodiments, chambered member **1120** may be made from any of the materials previously discussed for chambered member **120** in FIGS. **1-6**.

[0140] In some embodiments, upper member **1180** may be made from glass composite, chambered member **1170** may be made from carbon or carbon composite, and intermediate member **1190** may be made from carbon or carbon composite. In some embodiments, indentation **1183** in top surface **1181** of upper member **1180**, indentation **1193** in top surface **1191** of intermediate member **1190**, and chambered member **1170**, may be Y-shaped. In some embodiments, chambered member **1170** may have a honeycomb volume. In such an embodiment, the rigidity of the sole structure **1100** may be increased in the area of the chambered member **1100** since a portion of the flexible glass composite volume of the upper member **1180** is being replaced by a rigid carbon or carbon composite having a honeycomb volume.

[0141] In some embodiments, provisions may be included for providing rigidity to some areas of the sole structure **100**, while also providing enough flexibility to allow for twisting and bending. For example, a rigid layer of material may extend into some of the cleat members in the forefoot region in order to provide rigidity there. The rigid layer of material may extend into other areas of the sole structure **100** in order to provide a large surface area capable of absorbing and dissipating impact forces imparted on the cleat members. A flexible layer of material may also extend into the cleat members in order to further absorb and dissipate forces felt on the cleat members and to allow for flexibility in the region. FIG. **12** illustrates one embodiment of cleat members having multiple layers associated with the sole structure **100** described in FIGS. **1-6**. In the embodiment shown in FIG. **12**, all the components in FIG. **1** have been assembled. As can be seen in FIG. **12**, first cleat member **1110**, second cleat member **1120**, third cleat member **1130** and fourth cleat member **1140** may extend from the bottom surface **172** of the forefoot region **149** of bottom member **140**. In some embodiments, fifth cleat member **1150** and sixth cleat member **1160** may extend from the bottom surface **172** of the heel region **147** of bottom member **140**.

[0142] In some embodiments, a portion of the cleat member may be designed to penetrate into the ground surface. The term "penetrating portion" as used throughout this detailed description and in the claims refers to any portion of a cleat member that is configured to penetrate into a ground surface. In some embodiments, penetrating portions may provide traction between the sole structure **100** and the ground surface. In some embodiments, a portion of the first cleat member **1110**, second cleat member **1120**, third cleat member **1130**, fourth cleat member **1140**, fifth cleat member **1150** and/or sixth cleat member **1160** may form a penetrating portion. For example, as seen in FIG. **12**, the ground penetrating portion of first cleat member **1110** includes protruding portion **145** of bottom member **140**, protruding portion **135** of intermediate member **130** and protruding portion **115** of upper member **110**. Likewise, the ground penetrating portion of second cleat member **1120** includes protruding portion **146** of bottom member **140**, protruding portion **136** of intermediate member **130** and protruding portion **116** of upper member **110**.

[0143] In some embodiments, cleat members may include one or more layers of materials in order to achieve the desired rigidity and/or flexibility. FIG. **12** shows a cross-sectional view of first cleat member **1110** and second cleat member **1120**. Referencing FIG. **12**, first cleat member **1110** may be associated with third protruding portion **115** in upper member **110**, third protruding portion **135** in intermediate member **130**, and third protruding portion **145** in bottom member **140**. Similarly, second cleat member **1120** may be associated with fourth protruding portion **116** in upper member **110**, fourth protruding portion **136** in intermediate member **130**, and fourth protruding portion **146** in bottom member **140**. In some embodiments, each of these protruding portions may form a dome-like shape in such a way as to cooperate with one another. However, in some embodiments, the protruding portions may have different shapes from one another. In some embodiments, fourth protruding portion **116** in upper member **110** and fourth protruding portion **136** in intermediate member **130** may form a dome-like shape, while fourth protruding portion **146** may have a flat tip **1146** in order to mate with cleat tip **156**. Likewise, third protruding portion **115** in upper member **110** and third protruding portion **135** in intermediate member **130** may form a dome-like shape, while third protruding portion **145** in bottom member **140** may have a flat tip **1146** in order to mate with cleat tip **155**. Cleat tip **155** may be attached to the outer surface of the third protruding portion **145** formed on the bottom surface **172** of bottom member **140**. Similarly, cleat tip **156** may be attached to the outer surface of the fourth protruding portion **146** on the bottom surface **172** of bottom member **140**.

[0144] It will be understood that while the current embodiments use elongated and/or rectangular shaped cleat members, cleat members may be formed in any of various shapes, including but not limited to: hexagonal, cylindrical, conical, conical frustum, round, circular, square, rectangular, rectangular frustum, trapezoidal, diamond, ovoid, as well as any other shape known to those in the art.

[0145] In some embodiments the length of the cleat members may vary. For example, in some embodiments, cleat members may extend further into the ground in order to increase traction. In other embodiments, cleat members may extend less into the ground in order to improve the wearer's ability to change directions quickly.

[0146] In some embodiments, longer cleat members may be desired. FIG. **12** illustrates a possible relationship between first cleat member **1110**, second cleat member **1120**, and plane **1105**. For example, the apex of each protruding portion in each layer of each cleat member may extend beyond plane **1105** of the outer bottom surface **172** of the bottom member **140**.

[0147] Referring to FIG. **12**, each layer of second cleat member **1120** may extend beyond plane **1105** of the outer bottom surface **172** of the bottom member **140**. In some embodiments, apex **1116** of fourth protruding portion **116** in upper member **110**, apex **1136** of fourth protruding portion **136** in intermediate member **130**, and apex **1146** of fourth protruding portion **146** in bottom member **140** may extend outwardly beyond plane **1105**.

[0148] In other embodiments, not every layer of second cleat member **1120** extends beyond plane **1105**. In some embodiments, apex **1146** of fourth protruding portion **146** in bottom member **140** may extend outwardly beyond plane **1105**, while apex **1136** of fourth protruding portion **136** in intermediate member **130** and apex **1116** of fourth protruding portion **116** in upper member **110** do not extend beyond plane **1105**. In some embodiments, apex **1146** of fourth protruding portion **146** in bottom member **140** and apex **1136** of fourth protruding portion **136** in intermediate member **130** may extend outwardly beyond plane **1105**, while apex **1116** of fourth protruding portion **116** in upper member **110** does not extend beyond plane **1105**. In another embodiment, apex **1146**, apex **1136** and apex **1116** do not extend beyond plane **1105**.

[0149] First cleat member **1110** may have a similar relationship with plane **1105**. In some embodiments, apex **1115** of third protruding portion **115** in upper member **110**, apex **1135** of third protruding portion **135** in intermediate member **130**, and apex **1145** of third protruding portion **145** in bottom member **140** may extend outwardly beyond plane **1105**.

[0150] In other embodiments, not every layer of first cleat member **1110** extends beyond plane **1105**. In some embodiments, apex **1145** of third protruding portion **145** may extend outwardly beyond plane **1105**, while apex **1135** of third protruding portion **135** in intermediate member **130** and apex **1115** of third protruding portion **115** in upper member **110** do not extend beyond plane **1105**. In some embodiments, apex **1145** of third protruding portion **145** in bottom member **140** and apex **1135** of third protruding portion **135** in intermediate member **130** may extend outwardly beyond plane **1105**, while apex **1115** of third protruding portion **115** in upper member **110** does not extend beyond plane **1105**. In another embodiment, apex **1145**, apex **1135** and apex **1115** do not extend beyond plane **1105**.

[0151] Third cleat member **1130** and fourth cleat member **1140**, located on the forefoot region **149** of the bottom surface **172** of bottom member **140**, may also include similar properties and relationships as discussed in FIG. **12** for first cleat member **1110** and second cleat member **1120**. Although FIG. **12** shows only four cleat members associated with the forefoot region **149** of bottom surface **140**, other embodiments may include more or less cleat members in the forefoot region **149**. Additionally, fifth cleat member **1150** and sixth cleat member **1160** located in the heel region **147** of the bottom surface **172** of bottom member **140**, may include similar properties and relationships as discussed in FIG. **12** for first cleat member **1110** and second cleat member **1120**.

[0152] Although the embodiments discussed in FIG. **12** include cleat members having an upper member **110**, an intermediate member **130**, a bottom member **140** and cleat tips **150**, other embodiments may include varying layers associated with the cleat members. In some embodiments, cleat members may include layers arranged in a different order than that described in FIG. **12**. For example, in some embodiments cleat members may include layers as described in FIGS. **7-11**. In some embodiments, cleat members may include a chambered member **1020**, as described in the embodiment disclosed in FIG. **10**. The details and relationships discussed in FIG. **12** may also be applied to any other embodiment discussed in FIGS. **1-11**.

[0153] In some embodiments, provisions may be included to further support the cleat members. In some embodiments, as shown in FIG. **13**, blade-like projections may abut and support each cleat member in the forefoot region **149**. FIG. **13** shows one embodiment of the forefoot region **149** of the bottom surface **172** of the bottom member **140**. FIG. **13** also shows an enlarged isometric view of second cleat member **1120**, which may include a first blade-like projection **1210**, second blade-like projection **1220** and third blade-like projection **1230**.

[0154] Some embodiments may include a first blade-like projection **1210**. The first blade-like projection **1210** may have a first edge **1211**, a second edge **1212** and a third edge **1213**. The first edge **1211** may be attached to the bottom surface **172** of bottom member **140**. The second edge **1212** may be attached to at least a portion of fourth protruding portion **146**. The third edge **1213** may slope from the top corner **1214** of the second edge **1212** to the bottom surface **172** of bottom member **140**. In some embodiments, third edge **1213** may form a straight line between top corner **1214** of the second edge **1212** and the bottom surface **172** of bottom member **140**. In other embodiments, the third edge **1213** may be curved, or form an arc.

[0155] Some embodiments may include a second blade-like projection **1220**. The second blade-like projection **1220** has a first edge **1221**, a second edge **1222** and a third edge **1223**. The first edge **1221** is attached to the bottom surface **172** of bottom member **140**. The second edge **1222** is attached to at least a portion of fourth protruding portion **146**. The third edge **1223** slopes from the top corner **1224** of the second edge **1222** to the bottom surface **172** of bottom member **140**. In some embodiments, third edge **1223** may form a straight line between top corner **1224** of the second edge **1222** and the bottom surface **172** of bottom member **140**. In other embodiments, third edge **1223** may be curved, or form an arc.

[0156] In some embodiments, the first blade-like projection **1210** may extend away from fourth protruding portion **146** at an angle alpha (α) in relation to the second blade-like projection **1220**. In some embodiments, α may be substantially equal to 90°. In other embodiments, α may be greater than or less than 90°. For example, in some embodiments, α is substantially equal to 80°. In another embodiment, α is substantially equal to 100°.

[0157] Some embodiments may include a third blade-like projection **1230**. The third blade-like projection **1230** has a first edge **1231**, a second edge **1232** and a third edge **1233**. The first edge **1221** is attached to the bottom surface **172** of bottom member **140**. The second edge **1232** is attached to at least a portion of fourth protruding portion **146**. The third edge **1233** slopes from the top corner **1234** of the second edge **1232** to the bottom surface **172** of bottom member **140**. In some embodiments, third edge **1233** may form a straight line between top corner **1234** of the second edge **1232** and the bottom surface **172** of bottom member **140**. In other embodiments, third edge **1233** may be curved, or form an arc.

[0158] In some embodiments, the third blade-like projection **1230** may extend away from fourth protruding portion **146** at an angle beta (β) in relation to the second blade-like projection **1220**. In some embodiments, β may be substantially equal to 90°. In other embodiments, β may be greater than or less than 90°. For example, in some embodiments, β is substantially equal to 80°. In another embodiment, β is substantially equal to 100°.

[0159] Although FIG. **13** illustrates a cleat member having three blade-like projections, some embodiments may include more or less blade-like projections. The blade-like projections provide the wearer with improved push off capabilities. In addition, the blade-like projections allow the wearer to more easily change directions since a larger surface area contacts the ground when pushing off. Although FIG. **13** illustrates blade-like projections for cleat members in the forefoot region **149**, cleat members in the midfoot region **148** and heel region **147** may also include blade-like projections as discussed in FIG. **13**.

[0160] Cleat members in the heel region **147** may also include blade-like projections. FIG. **14** illustrates an enlarged isometric perspective of cleat member **1150** and cleat member **1160** in the heel region **147** of bottom member **140**. Referring to FIG. **14**, cleat member **1150** includes first blade-like projection **1451**, second blade-like projection **1450** and third blade-like projection **1455** extending outwardly from the bottom surface **172** of bottom member **140**. First blade-like projection **1451**, second blade-like projection **1450** and third blade-like projection **1455** abut and support cleat member **1160** and have a similar relationship with cleat member **1160** as the relationship between second cleat member **1120** and first blade-like projection **1210**, second blade-like projection **1220** and third blade-like projection **1230** discussed in FIG. **13**. Similarly, cleat member **1150** includes first blade-like projection **1461**, second blade-like projection **1450** and third blade-like projection **1465** extending outwardly from the bottom surface **172** of bottom member **140**. First blade-like projection **1461**, second blade-like projection **1450** and third blade-like projection **1465** abut and support cleat member **1150** and have a similar relationship with cleat member **1150** as the relationship between second cleat member **1120** and first blade-like projection **1210**, second blade-like projection **1220** and third blade-like projection **1230** described and discussed in FIG. **13**.

[0161] In some embodiments, second blade-like projection **1450** may form one lateral projection between cleat member **1160** and cleat member **1150**. Forming one lateral projection would increase push-off capability of the wearer and enhance the wearer's capability to change directions.

[0162] In some embodiments, provisions may be made for including additional features on the bottom member in order to reduce the weight of the sole structure and/or to improve traction. The embodiments described in FIG. **15** may be associated with any embodiment discussed in FIGS. **1-14**. The embodiments described in FIG. **15** may include similar properties and relationships as those discussed in FIGS. **1-14**. Referring to FIG. **15**, one embodiment of a bottom member **1500** may include a heel region **1514**, midfoot region **1512** and a forefoot region **1510**.

[0163] In some embodiments, provisions may be included on bottom member **1500** in order to increase the traction between the wearer's foot and the ground surface. In some embodiments, bottom member **1500** may include a plurality of individual projections forming a first textured region **1570** on the bottom surface **1572** of the heel region **1514** of bottom member **1500**. The first textured region **1572** provides for additional traction and enhances the wearer's ability to change directions.

[0164] In some embodiments, the shape of the individual projections in first textured region **1570** may vary. In some embodiments, the projections may be triangular or pyramid shaped. In other embodiments, the projections could have any other shape having a point.

[0165] In different embodiments, a textured region could be formed in any manner. In some embodiments, first textured region **1570** may be formed when molding the bottom member **1500**. In some embodiments, first textured region **1570** may be formed by cutting the formation after molding, such as by a waterjet or laser.

[0166] In some embodiments, bottom member **1500** may include a plurality of projections forming a second textured region **1560** on the bottom surface **1572** of the forefoot region **1510** of bottom member **1500**. The second textured region **1560** provides for additional traction and enhances the wearer's ability to change directions. In some cases, the projections of second textured region **1560** may be substantially similar to the projections of first textured region **1570**.

[0167] In some embodiments, provisions may be included to reduce the weight of bottom member **1500**. In some embodiments, openings may be made in portions of bottom member in order to reduce the overall weight of bottom member **1500**. In some embodiments, a heel opening **1520** may be included in the heel region **1514** of bottom member **1500**. In some embodiments, a midfoot opening **1525** may be included in the midfoot region **1512** of bottom member **1500**. In some embodiments, a forefoot opening **1530** may be included in the forefoot region **1510** of bottom member **1500**.

[0168] In some embodiments, provisions may be included to increase the rigidity of bottom member **1500**. In some embodiments, bottom member **1500** may include a spinal structure **1565** associated with the bottom surface **1572**. In some embodiments, spinal structure **1565** may include a series of diamond and/or triangular shaped structures running in the direction of the heel region **1514** to the forefoot region **1510**. The spinal structure **1565** may provide additional structural support to bottom surface **1572** of bottom member **1500**.

[0169] In some embodiments, the shape of the individual structures of making up the spinal structure **1565** may vary. In some embodiments, the spinal structure **1565** may be made from a series of square-shaped structures. In some embodiments, the spinal structure **1565** may be made from any other shape of individual structures.

[0170] In some embodiments, the location of the spinal structure **1565** may vary. In some embodiments, as shown in FIG. **15**, the spinal structure **1565** may run in a longitudinal direction in the center of the midfoot opening **1525** of bottom member **1500**. However, in other embodiments, the spinal structure **1565** may extend in a longitudinal or lateral direction in any of the openings in the bottom member **1500**. In still further embodiments, the spinal structure **1565** may extend in a longitudinal direction on the bottom surface **1572** of bottom member **1500**. In still further embodiments, spinal structure **1565** may be associated with any portion of the bottom member **1500** in order to increase the rigidity of the bottom member **1500**.

[0171] While various embodiments of the have been described, the description is intended to be exemplary, rather than limiting and it will be apparent to those in the art that many more embodiments and implementations are possible that are within the scope of the current embodiments. Accordingly, the embodiments are not to be restricted except in light of the attached claims and their equivalents. Also, various modifications and changes may be made within the scope of the attached claims.

What is claimed is:

1. A sole structure, comprising:

a bottom member having a top surface, a bottom surface, a forefoot region, a midsole region and a heel region, wherein the top surface of the forefoot region of the bottom member has a first protruding portion associated with a cleat member;

an intermediate member having a first projection, second projection, and third projection, the intermediate member further having a top surface, a bottom surface, a forefoot region, a midsole region and a heel region;

the first projection and second projection being located in the forefoot region of the intermediate member and the third projection extending through the midsole region into the heel region of the intermediate member;

the bottom surface of the first projection having a second protruding portion associated with the cleat member; and

wherein the second protruding portion in the bottom surface of the first projection associates with the first protruding portion in the top surface of the bottom member.

2. The sole structure according to claim **1**, wherein the protruding portion in the top surface of the bottom member and the protruding portion in the bottom surface of the intermediate member are similarly shaped.

3. The sole structure according to claim **1**, wherein the first projection, second projection and third projection are lobe-shaped.

4. The sole structure according to claim **1**, wherein the intermediate member is made from material that is more rigid than the bottom member.

5. The sole structure according to claim **1**, wherein the intermediate member is made from a carbon fiber.

6. The sole structure according to claim **1**, further including:

a cleat tip associated with the bottom surface of the bottom member in the forefoot region corresponding to the first protruding portion.

7. The sole structure according to claim **6**, wherein the bottom surface of the forefoot region of the bottom member includes a plurality of pyramid-shaped projections forming a textured region.

8. A sole structure, comprising:

a bottom member having a top surface and a bottom surface;

an intermediate member having a top surface and a bottom surface, wherein the intermediate member having an indentation that is concave relative to the top surface of the intermediate member, wherein the bottom surface of the intermediate member is attached to the top surface of the bottom member; and

a chambered member configured to be inserted within the indentation on the top surface of the intermediate member.

9. The sole structure according to claim **8**, wherein the chambered member is formed by injecting a material into the indentation of the intermediate member.

10. The sole structure according to claim **8**, further including:

an upper member having a top surface and a bottom surface, wherein the bottom surface of the upper member is attached to the top surface of the intermediate member.

11. The sole structure according to claim **10**, wherein the upper member is attached to the intermediate member using heat and pressure.

12. The sole structure according to claim **10**, wherein the upper member is formed from a material that is shaped using a waterjet.

13. The sole structure according to claim **10**, wherein the upper member is attached to the intermediate member using a thermoplastic polyurethane.

14. The sole structure according to claim **10**, wherein the upper member is made from a glass composite, and the intermediate member is made from a glass composite.

15. A sole structure, comprising:

a bottom member having a bottom surface;

a cleat member associated with the bottom member, the cleat member having an outer layer, an intermediate layer, and an inner layer.

16. The sole structure according to claim 15, wherein the outer layer is made of plastic, the intermediate layer is made of carbon and the inner layer is made of fiberglass.

17. The sole structure according to claim 15, wherein the outer layer of the cleat member has a tapered shape.

18. The sole structure according to claim 15, wherein the intermediate layer and the inner layer of the cleat member are dome-shaped.

19. The sole structure according to claim 18, wherein an apex of the dome of the intermediate layer extends beyond a plane including the bottom surface of the sole structure, and wherein an apex of the dome of the inner layer extends beyond a plane including the bottom surface of the sole structure.

20. The sole structure according to claim 15, wherein the outer layer of the cleat member and the bottom surface of the sole structure are formed as one molded piece.

21. The sole structure according to claim 15, wherein the cleat member forms a rectangular frustum shape.

22. The sole structure according to claim 15, further comprising:

a first blade-like projection extending outwardly from, and substantially perpendicular to, the bottom surface of the sole structure, wherein at least one side of the blade-like projection buttresses the outer layer of the cleat member.

23. The sole structure according to claim 22, further comprising:

a second blade-like projection extending outwardly from, and substantially perpendicular to, the bottom surface of the sole structure, wherein at least one side of the blade-like projection buttresses the outer layer of the cleat member, wherein the first blade-like projection and the second blade-like projection is spaced

24. A method of making a sole structure, comprising:

forming an upper member, wherein the upper member having a top surface, and a bottom surface;

forming an intermediate member, wherein the intermediate member having a top surface and a bottom surface, wherein the top surface of the intermediate member includes a concave indentation;

placing the top surface of the intermediate member in contact with the bottom surface of the upper member; and

injecting a chambered member into the indentation of the intermediate member, wherein the chambered member having a honeycomb volume.

25. The method of claim 24, wherein the indentation and the chambered member are Y-shaped.

26. The method of claim 24, wherein the intermediate member, upper member and chambered member are bonded together using a heat press.

27. The method of claim 24, wherein the intermediate member, upper member and chambered member are bonded together using thermoplastic polyurethane.

28. The method of claim 24, wherein the intermediate member is formed from a carbon composite.

29. The method of claim 24, wherein the upper member is formed from a glass composite.

30. An article of footwear, comprising:

a sole structure having a forefoot region, a midfoot region and a heel region, wherein the sole structure includes a plurality of layers comprising:

a first zone of flexibility located in the forefoot region;

a second zone of flexibility located in the forefoot region, wherein the second zone of flexibility is more rigid than the first zone of flexibility; and

a third zone of flexibility located in the midfoot region, wherein the third zone of flexibility is more rigid than the first and second zone of flexibility.

31. The sole structure of claim 30, wherein the first zone includes a layer of fiberglass composite material.

32. The sole structure of claim 30, wherein the second zone includes a layer of fiberglass composite material and a layer of solid carbon composite material.

33. The sole structure of claim 30, wherein the third zone includes a layer of fiberglass composite material, a layer of solid carbon composite material and a layer of carbon composite material having a honeycomb volume.

34. The sole structure of claim 31, wherein the fiberglass composite material layer is thicker in the first zone than in the second zone.

35. The sole structure of claim 32, wherein the solid carbon composite material layer in the second zone is thinner than the fiberglass composite layer in the second zone.

36. The sole structure of claim 33, wherein the thickness of the layer made of carbon composite material having a honeycomb volume is thinner than the fiberglass composite material layer.

37. A sole structure, comprising:

a bottom member having a forefoot region, midfoot region, heel region, to surface and bottom surface, the bottom surface of the bottom member forming an outer surface of the sole structure;

a cleat member extending from the bottom member, the cleat member including a penetrating portion that is configured to penetrate into a ground surface;

an intermediate member having a top surface and a bottom surface, the intermediate member configured to provide structural support for the sole structure; and

wherein the bottom surface of the intermediate member associates with the top surface of the bottom member, wherein a portion of the intermediate member extends into the penetrating portion of the cleat member.

38. The sole structure according to claim 37, wherein the intermediate member associates with the forefoot region of the bottom member.

39. The sole structure according to claim 37, wherein the intermediate member associates with the forefoot region and midfoot region of the bottom member.

40. The sole structure according to claim 37, wherein the intermediate member associates with the midfoot region, heel region and forefoot region of the bottom member.

41. A sole structure comprising:

an upper member having a top surface and a bottom surface, the upper member having a first concave indentation in the top surface and a corresponding convex indentation extending from the bottom surface of the upper member;

an intermediate member having a top surface, the intermediate member having a second concave indentation in the top surface of the intermediate member, wherein the second concave indentation in the top surface of the intermediate member is configured to receive the convex indentation extending from the bottom surface of the upper member; and

a chambered member configured to be inserted within the first concave indentation in the top surface of the upper member.

42. The sole structure of claim **41**, wherein the upper member having a first length and the intermediate member having a second length, wherein the first length is greater than the second length.

43. The sole structure of claim **41**, further comprising:

a bottom member having a top surface, wherein the top surface of the bottom member is configured to be associated with the bottom surface of the intermediate member.

44. The sole structure of claim **41**, wherein the intermediate member and the upper member are made from materials having fibers.
