TITLE
Inhibitors of Hepatitis C Virus NS3 Protease

FIELD OF THE INVENTION
The present invention relates generally to a novel class of pyrimidinones that are useful as serine protease inhibitors, and more particularly as Hepatitis C virus NS3 protease inhibitors. This invention also relates to pharmaceutical compositions comprising these compounds and methods of using the same.

BACKGROUND OF THE INVENTION
Hepatitis C virus (HCV) is the major cause of transfusion and community-acquired non-A, non-B hepatitis worldwide. Approximately 2% of the world's population are infected with the virus. In the Unites States, hepatitis C represents approximately 20% of cases of acute hepatitis. Unfortunately, self-limited hepatitis is not the most common course of acute HCV infection. In the majority of patients, symptoms of acute hepatitis resolve, but alanine aminotransferase (a liver enzyme diagnostic for liver damage) levels often remain elevated and HCV RNA persists. Indeed, a propensity to chronicity is the most distinguishing characteristic of hepatitis C, occurring in at least 85% of patients with acute HCV infection. The factors that lead to chronicity in hepatitis C are not well defined. Chronic HCV infection is associated with increased incidence of liver cirrhosis and liver cancer. No vaccines are available for this virus, and current treatment is restricted to the use of alpha interferon, which is effective in only 15-20% of patients. Recent clinical studies have shown that combination therapy of alpha interferon and ribavirin leads to sustained efficacy in 40% of patients (Poynard et al. Lancet 1998, 352, 1426-1432.). However, a majority of patients still either fail to respond or relapse after completion of therapy. Thus, there is a clear need to develop more effective therapeutics for treatment of HCV-associated hepatitis.
HCV is a positive-stranded RNA virus. Based on comparison of deduced amino acid sequence and the extensive similarity in the 5’ untranslated region, HCV has been classified as a separate genus in the Flaviviridae family, which also includes flaviviruses such as yellow fever virus and animal pestiviruses like bovine viral diarrhea virus and swine fever virus. All members of the Flaviviridae family have enveloped virions that contain a positive stranded RNA genome encoding all known virus-specific proteins via translation of a single, uninterrupted, open reading frame.

Considerable heterogeneity is found within the nucleotide and encoded amino acid sequence throughout the HCV genome. At least six major genotypes have been characterized, and more than 50 subtypes have been described. The major genotypes of HCV differ in their distribution worldwide, and the clinical significance of the genetic heterogeneity of HCV remains elusive despite numerous studies of the possible effect of genotypes on pathogenesis and therapy.

The RNA genome is about 9.6 Kb in length, and encodes a single polypeptide of about 3000 amino acids. The 5’ untranslated region contains an internal ribosome entry site (IRES), which directs cellular ribosomes to the correct AUG for initiation of translation. As was determined by transient expression of cloned HCV cDNAs, the precursor protein is cotranslationally and posttranslationally processed into at least 10 viral structural and nonstructural (NS) proteins by the action of a host signal peptidase and by two distinct viral proteinase activities. The translated product contains the following proteins: core-E1-E2-p7-NS2-NS3-NS4A-NS4B-NS5A-NS5B.

The N-terminal portion of NS3 functions as a proteolytic enzyme that is responsible for the cleavage of sites liberating the nonstructural proteins NS4A, NS4B, NS5A, and NS5B. NS3 has further been shown to be a serine
protease. Although the functions of the NS proteins are not completely defined, it is known that NS4A is a protease cofactor and NS5B is an RNA polymerase involved in viral replication. Thus agents that inhibit NS3 proteolytic processing of the viral polyprotein are expected to have antiviral activity.

There are several patents that disclose HCV NS3 protease inhibitors. WO98/17679 describes peptide and peptidomimetic inhibitors with the following formula: U-E^8-E^7-E^6-E^5-E^4-NH-CH(CH_2G^1)-W^1, where W is one of a variety of electrophilic groups, including boronic acid or ester. E^4 represents either an amino acid or one of a series of peptidomimetic groups, the synthesis of which are not exemplified. HCV protease inhibitors described in the present case are not covered.

Based on the large number of persons currently infected with HCV and the limited treatments available, it is desirable to discover new inhibitors of HCV NS3 protease.

The compounds herein described may have asymmetric
centers. All chiral, diastereomeric, and racemic forms are
included in the present invention. Many geometric isomers
of olefins, C=N double bonds, and the like can also be
present in the compounds described herein, and all such
stable isomers are contemplated in the present invention.

It will be appreciated that certain compounds of the
present invention contain an asymmetrically substituted
carbon atom, and may be isolated in optically active or
racemic forms. It is well known in the art how to prepare
optically active forms, such as by resolution of racemic
forms or by synthesis, from optically active starting
materials. Also, it is realized that cis and trans
generic isomers of the compounds of the present invention
are described and may be isolated as a mixture of isomers or as separated isomeric forms. All chiral, diastereomeric, racemic forms and all geometric isomeric forms of a structure are intended, unless the specific stereochemistry or isomer form is specifically indicated.

The reactions of the synthetic methods claimed herein are carried out in suitable solvents which may be readily selected by one skilled in the art of organic synthesis, said suitable solvents generally being any solvent which is substantially nonreactive with the starting materials (reactants), the intermediates, or products at the temperatures at which the reactions are carried out. A given reaction may be carried out in one solvent or a mixture of more than one solvent. Depending on the particular reaction step, suitable solvents for a particular reaction step may be selected.

Combinations of substituents and/or variables are permissible only if such combinations result in stable compounds. By stable compound or stable structure it is meant herein a compound that is sufficiently robust to survive isolation to a useful degree of purity from a reaction mixture, and formulation into an efficacious therapeutic agent.

The term "substituted," as used herein, means that any one or more hydrogens on the designated atom is replaced with a selection from the indicated group, provided that the designated atom's normal valency is not exceeded, and that the substitution results in a stable compound. When a substituent is keto (i.e., =O), then two hydrogens on the atom are replaced.

When any variable (e.g., R^4\text{a} or R^{11}) occurs more than one time in any constituent or formula for a compound, its definition at each occurrence is independent of its definition at every other occurrence. Thus, for example, if a group is shown to be substituted with 0-3 R^4\text{a}, then said group may optionally be substituted with up to three R^4\text{a} groups and R^4\text{a} at each occurrence is selected.
independently from the definition of \( R^{a} \). Also, combinations of substituents and/or variables are permissible only if such combinations result in stable compounds. By stable compound it is meant herein a compound that is sufficiently robust to survive isolation to a useful degree of purity from a reaction mixture.

When a bond to a substituent is shown to cross a bond connecting two atoms in a ring, then such substituent may be bonded to any atom on the ring. When a substituent is listed without indicating the atom via which such substituent is bonded to the rest of the compound of a given formula, then such substituent may be bonded via any atom in such substituent. Combinations of substituents and/or variables are permissible only if such combinations result in stable compounds.

SYNTHESIS

The compounds of the present invention can be prepared in a number of ways well known to one skilled in the art of organic synthesis. The compounds of the present invention can be synthesized using the methods described below, together with synthetic methods known in the art of synthetic organic chemistry, or variations thereon as appreciated by those skilled in the art. Preferred methods include, but are not limited to, those described below. All references cited herein are hereby incorporated in their entirety herein by reference.

The novel compounds of this invention may be prepared using the reactions and techniques described in this section. The reactions are performed in solvents appropriate to the reagents and materials employed and are suitable for the transformations being effected. Also, in the description of the synthetic methods described below, it is to be understood that all proposed reaction conditions, including choice of solvent, reaction atmosphere, reaction temperature, duration of the experiment and workup procedures, are chosen to be the conditions standard for that reaction, which should be readily recognized by one skilled in the art. It is understood by one skilled in the art of organic synthesis that the functionality present on various portions of the molecule must be compatible with the reagents and reactions proposed. Such restrictions to the substituents that are compatible with the reaction conditions will be readily apparent to one skilled in the art and alternate methods must then be used.
The compounds of this invention are intended to interact with the catalytic serine hydroxyl of Hepatitis C NS3 protease, and therefore incorporate an electrophilic moiety capable of such interaction. In the synthetic schemes below, this moiety, or its synthetic equivalent or precursor, is referred to as a "serine trap" and is defined by structure 1.11.

**Synthesis of inhibitors 1.13, 2.3, 2.6, 2.9, 2.12, 2.14**

Schemes 1 and 2A-2D illustrate the synthesis of inhibitors of structure 1.13, 2.3, 2.6, 2.9, 2.12, and 2.14. In Schemes 1 and 2A-2D, W is as defined above, P is a nitrogen protecting group, and R is a standard leaving group for carboxylic acids, wherein such protecting and leaving groups are known to one skilled in the art.

The synthesis of inhibitor 1.13 is depicted in Scheme 1. An intermediate in this synthesis, Bicyclic pyrimidinone 1.9 (n = 1), is prepared as previously described by Webber et al. (Webber, S. E.; Dragovich, P. S.; Littlefield, E. S.; Marakovits, J. T.; Babine, R. E. WO 99/31122) and is described in the scheme. Lactam 1.1 (n = 0-3) is protected as ester 1.2, which is subsequently converted to thiolactam 1.3 by treatment with Lawesson's reagent. Thiolactam 1.3 is alkylated with MeI to afford 1.4, which is displaced with ammonium chloride providing amidine 1.5. Compound 1.5 is condensed with dimethyl methoxymethylenemalonate to afford bicyclic pyrimidinone 1.6. The methyl ester functionality of ester 1.6 is cleaved with aqueous base to afford acid 1.7, which is then subjected to a Curtius rearrangement using diphenylphosphoryl azide and a suitable alcohol to afford carbamate 1.8. At this point, an R⁻ substituent may be introduced via NaH induced alkylation of the carbamate nitrogen and the R substituent of the ester may be modified or converted to the corresponding amide via standard (EDCI/HOAt) amide coupling of the corresponding acid. This compound then can be deprotonated with strong base, and the resultant anion reacted with electrophiles. In this way,
one or two electrophiles (reaction with R³-X'' and R¹³-X'') may be introduced to give substituted bicyclic pyrimidinone 1.7. In addition, electrophiles such as aldehydes and epoxides may be employed and the resultant carbanols may optionally be eliminated to afford the alkene. At this point, substituents R³ and R¹³ of compound 1.8 may optionally be modified, followed by deprotection to reveal carboxylic acid 1.9. Peptide coupling of acid 1.10 with serine-trap 1.11 affords amide 1.12. At this point, the R-derivative carbamate functionality is cleaved. Optionally, R¹, R³, and R¹³ functionality may be modified and R² may be introduced to afford inhibitor 1.13.

Inhibitor 2.3 is prepared by deprotonation of lactam 2.1 (n = 0-3) and reaction with electrophile(s) to provide compound 2-2, either monosubstituted or disubstituted, followed by a reaction sequence similar to the preparation of inhibitor 1.13. Similarly, inhibitor 2.6 is prepared beginning with cyclic amine 2.4 (N = 0-3), which is made according to the chemistry described by Sardina et al. (Blanco et al., J. Org. Chem. 1999, 64, 8786-8793). Cyclic amine 2.4 (n = 0-3) is oxidized with ruthenium oxide in a two-phase system (Yoshifuji et al., Chem. Pharma. Bull. 1986, 34, 3873-3878.) to the corresponding lactam 2.5. Lactam 2.5 (n = 1) may also be prepared according to chemistry developed by Hruby, V. J. et al. (Soloshonok et al. J. Org. Lett. 2000, 2, 747-750). Following chemistry described above, lactam 2.5 is converted into inhibitor 2.6.

Inhibitor 2.9 is prepared analogously to inhibitor 1.13 from piperazinone 2.8. Compound 2-8 is prepared via reductive amination of piperazinone 2-7, which is prepared according to the chemistry developed by Aebischer et al. (Helv. Chim. Acta 1989, 72, 1043-51). Inhibitor 2.12 is prepared from bicyclic pyrimidinone 2.11 via chemistry analogous to the preparation of inhibitor 1.13.

Intermediate 2.11 in turn is prepared via a condensation amidine 1.5 and methylene malonate 2.10 followed by N-
bromosuccinimide-promoted unsaturation. Compound 2.11 is prepared following chemistry described by Veale et al. (J. Org. Chem. 1993, 58, 4490-4493.). Inhibitor 2.14 is prepared from morpholinone 2.13 via chemistry analogous to the preparation of inhibitor 1.13. Intermediate 2.13 is prepared via a condensation of CbzSerOtBu and methyl bromoacetate.

Synthesis of a serine trap of structure 1.11
a) Synthesis of α-amino boronic ester

Scheme 3 outlines a route to mono-substituted amino boronic esters. In Scheme 3, a Grignard reagent is reacted with a borate ester 3.12a, which can be prepared by the reaction of pinanediol with trialkylborate, providing boronate 3.12b. Homologation of 3.12b with the anion of dichloromethane gives the α-chloro boronic ester 3.12c. (Matteson, D. S. & Majumdar, D., Organometallics 1983, 2, 1529-1535). Displacement of the chloride by lithium bis(trimethylsilyl)amide gives silyl amine 3.12d, which is
converted to the amine hydrochloride salt 3.12e with anhydrous HCl. (Matteson, D. S. & Sadhu, K. M., Organometallics 1984, 3, 1284-1288). Notice that 3.12e is shown protected as the pinanediol ester. This is the preferred protecting group, but other diol protecting groups, for example but not to be limiting the scope of workable and known diol protecting groups, pinacol, 1,2-ethanediol, 1,2-propanediol, 1,3-propanediol, 2,3-butanediol, 1,2-diisopropylethanediol, 5,6-decanediol, 1,2-dicyclohexylethanediol, are known to those skilled in the art.

Peptide boronic esters can be prepared from commercially available materials by methods known to one skilled in the art of organic synthesis. Peptide boronic acids and esters are generally well known in the art; however, for a general reference to synthesis of peptide boronic esters, see: Kettner, C; Forsyth, T. Houben-Weyl Methods of Organic Chemistry 1999, in press; for a reference to synthesis of fluorinated peptide residues see Matassa et al., PCT Application WO 9964442. More preferably, see techniques disclosed in copending commonly assigned U.S. Provisional Patent Application USSN 60/142,561, filed July 7, 1999; herein incorporated in its entirety by reference; as well as copending commonly assigned U.S. Provisional Patent Application USSN 60/145,631, filed July 26, 1999; herein incorporated in its entirety by reference.
b) Synthesis of α-ketoamide, α-ketoester and α-diketone

α-Ketoamides and other α-keto derivatives are generally introduced in the hydroxy form and oxidized to the active ketone form in the final synthetic step after it is coupled to the pyrazinone carboxylic acid \textbf{1.9}. Scheme 4 illustrates the synthesis of α-hydroxy esters and α-hydroxy amides. In Scheme 4, substituted acrylate ester \textbf{4.13a} is aminohydroxylated using a Sharpless’s procedure (Tao, B., Sharpless, K. B. et al. Tetrahedron Lett. \textbf{1998}, \textit{39}, 2507-2510) to Cbz-protected amino alcohols \textbf{4.13b}. Catalytic hydrogenation of \textbf{4.13b} gives α-hydroxy ketoester \textbf{4.13c}.

4.13a, are commercially available or may be easily prepared from commercially available materials.

Amines of formula H₂N-Q can be prepared from commercially available materials by methods known to one skilled in the art of organic synthesis. More preferably, see techniques disclosed in pending commonly assigned U.S. Provisional Patent Application USSN 60/168,998, filed December 3, 1999; herein incorporated in its entirety by reference.

c) Synthesis of amino trifluoromethyl and pentafluoroethyl ketones.

Similar to α-ketoamides and other α-keto derivatives, the trifluoromethyl or pentafluoroethyl ketone functionality is also introduced in the hydroxy form and oxidized to the active ketone form in the final step.
Scheme 5 illustrates the synthesis of amino trifluoromethyl alcohol (Skiles et al., *J. Med. Chem.* **1992**, *35*, 641-662) and amino pentafluoroethyl alcohol (Ogilvie et al., *J. Med. Chem.* **1997**, *40*, 4113-4135). In Scheme 5, a Henry reaction between a nitroalkane $R^1\text{NO}_2$ and trifluoroacetaldehyde ethyl hemiacetal affords nitro alcohol **5.14a**, which is hydrogenated over Ra-Ni and the resulting amino alcohol **5.14b** is converted to the N-Boc derivative **5.14c**. Treatment of the Boc-amine with anhydrous HCl affords the hydrochloride salt **5.14d**. A solid-phase synthesis of peptidyl trifluoromethyl ketones is also known, see: Poupart et al., *J. Org. Chem.* **1999**, *64*, 1356-1361. Alternatively, condensation of the Weinreb amide **5.15a** with CF$_3$CF$_2$Li followed by reduction with NaBH$_4$ gives pentafluoroethyl substituted alcohol **5.15b**. Deprotection of **5.15b** gives the amino alcohol salt **5.15d**.
d) Synthesis of difluoro α-ketoamide

Scheme 6 outlines the synthesis of hydroxy difluoro α-ketoamides (see: Veale et al., J. Med. Chem. 1997, 40, 3173-3181; Wolfe et al., J. Med. Chem. 1998, 41, 6-9). In Scheme 6, protected aminoaldehyde 6.16a (For preparation of α-aminoaldehyde, see: Fukuyama et al., J. Am. Chem. Soc. 1990, 112, 7050-7051 and Scheidt et al., Bioorg. Med. Chem. 1998, 6, 2477-2499) is reacted with 2-bromo-2,2-difluoroacetate to produce difluoro alcohol 6.16b. The alcohol 6.16b is hydrolyzed to the acid and coupled to an amine H₂N-Q to give 6.16c. The nitrogen protecting group Pg is removed according to procedures known to one skilled in the art (see Greene, T. W. in Protective Groups in Organic Synthesis, John Wiley & Sons, 2nd Ed, 1991), producing difluoro α-ketoamide 6.16d.
The serine traps described above are generally coupled to the free acid of the dihydropyrrolopyrazinone using known peptide coupling procedures, preferably by the phosphonium salt PyAOP (Carpino et al., J. Chem. Soc., Chem. Commun. 1994, 201-203). The alcohol functionality of the hydroxy serine trap is oxidized by procedures known to those skilled in the art, such as Dess-Martin periodinane method (Dess, D. B & Martin, J. C., J. Org. Chem. 1983, 48, 4155-4156) in the final step to give a compound of structure 1.11 and 1.12 wherein W contains an activated carbonyl.

When required, separation of the racemic material can be achieved by HPLC using a chiral column or by a resolution using a resolving agent such as camphoric chloride (Steven D. Young, et al, Antimicrobial Agents and Chemotherapy 1995, 2602-2605). A chiral compound may also be directly synthesized using a chiral catalyst or a chiral ligand (Andrew S. Thompson, et al, Tet. lett. 1995, 36, 8937-8940).

UTILITY

The compounds of Formula (I) are expected to inhibit the activity of Hepatitis C Virus NS3 protease and, therefore, to possess utility in the cure and prevention of
HCV infections. The NS3 protease inhibition is demonstrated using assays for NS3 protease activity, for example, using the assay described below for assaying inhibitors of NS3 protease. The compounds of Formula (I) are expected to show activity against NS3 protease in cells, as demonstrated by the cellular assay described below. A compound is considered to be active if it has an IC$_{50}$ value of less than about 100$\mu$M in this assay. It is more preferred if it has an IC$_{50}$ value of less than about 60$\mu$M. It is even more preferred if it has an IC$_{50}$ value of less than about 1$\mu$M. It is most preferred if it has an IC$_{50}$ value of less than about 0.1$\mu$M. Compounds of the present invention have been shown to have an IC$_{50}$ value of less than about 100$\mu$M in this assay.

Expression and Purification of NS3 Protease

The plasmid cflSODp600, containing the complete coding region of HCV NS3 protease, genotype 1a, was obtained from ATCC (database accession: DNA Seq. Acc. M62321, originally deposited by Chiron Corporation). PCR primers were designed that allow amplification of the DNA fragment encoding the NS3 protease catalytic domain (amino acids 1 to 192) as well as its two N-terminal fusions, a 5 amino acid leader sequence MGAQH (serving as a expression tag) and a 15 amino acid His tag MRGSHHHHHHHHGGAQH. The NS3 protease constructs were cloned in the bacterial expression vector under the control of the T7 promoter and transformed in E. coli BL 21 (DE3) cells. Expression of the NS3 protease was obtained by addition of 1 mM IPTG and cells were growing for additional 3h at 25°C. The NS3 protease constructs have several fold difference in expression level, but exhibit the same level of solubility and enzyme specific activity. A typical 10 L fermentation yielded approximately 200 g of wet cell paste. The cell paste was stored at -80°C. The NS3 protease was purified based on published procedures (Steinkuhler C. et al. Journal of Virology 70, 6694-6700, 1996 and Steinkuhler C. et al. Journal of Biological Chemistry 271, 6367-6373,
1996.) with some modifications. Briefly, the cells were resuspended in lysis buffer (10 mL/g) containing PBS buffer (20 mM sodium phosphate, pH 7.4, 140 mM NaCl), 50% glycerol, 10 mM DTT, 2% CHAPS and 1 mM PMSF. Cell lysis was performed with use of microfluidizer. After homogenizing, DNase was added to a final concentration 70 U/mL and cell lysate was incubated at 4°C for 20 min. After centrifugation at 18,000 rpm for 30 min at 4°C supernatant was applied on SP Sepharose column (Pharmacia), previously equilibrated at a flow rate 3 mL/min in buffer A (PBS buffer, 10% glycerol, 3 mM DTT). The column was extensively washed with buffer A and the protease was eluted by applying 25 column volumes of a linear 0.14 - 1.0 M NaCl gradient. NS3 containing fractions were pooled and concentrated on an Amicon stirred ultrafiltration cell using a YM-10 membrane. The enzyme was further purified on 26/60 Superdex 75 column (Pharmacia), equilibrated in buffer A. The sample was loaded at a flow rate 1 mL/min, the column was then washed with a buffer A at a flow rate 2 mL/min. Finally, the NS3 protease containing fractions were applied on Mono S 10/10 column (Pharmacia) equilibrated in 50 mM Tris.HCl buffer, pH 7.5, 10% glycerol and 1 mM DTT and operating at flow rate 2 mL/min. Enzyme was eluted by applying 20 column volumes of a linear 0.1 - 0.5 M NaCl gradient. Based on SDS-PAGE analysis as well as HPLC analysis and active site titration, the purity of the HCV NS3 1a protease was greater than 95%. The enzyme was stored at -70°C and diluted just prior to use.

**Enzyme Assays**

Concentrations of protease were determined in the absence of NS4a by using the peptide ester substrate Ac-DED(Edans)EEAbuΩ[COO]ASK(Dabcyl)-NH₂ (Taliani et al. Anal. Biochem. 240, 60-67, 1996.) and the inhibitor, H-Asp-Glu-Val-Val-Pro-boroAlg-OH (administered as a hydrolyzed compound to the boronic acid), and by using tight binding reaction conditions (Bieth, Methods Enzymol. 248, 59-85,
1995). Best data was obtained for an enzyme level of 50 nM. Alternately, protease (63 μg/mL) was allowed to react with 3 μM NS4a, 0.10 mM Ac-Glu-Glu-Ala-Cys-pNA, and varying level of H-Asp-Glu-Val-Val-Pro-boroAlg-OH (0–6 μM).

Concentrations of protease were determined from linear plots of Activity vs. [inhibitor]. Molar concentrations of proteases were determined from the x-intercept. 

K_m values were determined measuring the rate of hydrolysis of the ester substrate over a range of concentrations from 5.0 to 100 μM in the presence of 3 μM KKNS4a (KKGSVVIVGRIVLSGKPA1IPKK). Assay were run at 25°C, by incubating ~1 nM enzyme with NS4a for 5 min in 148 μL of buffer (50 mM Tri buffer, pH 7.0, 50% glycerol, 2% Chaps, and 5.0 mM DTT. Substrate (2.0 μL) in buffer was added and the reaction was allowed to proceed for 15 min. Reactions were quenched by adding 3.0 μL of 10% TFA, and the levels of hydrolysis were determined by HPLC. Aliquots (50 μL) were injected on the HPLC and linear gradients from 90% water, 10% acetonitrile and 0.10 % TFA to 10% water, 90% acetonitrile and 0.10% TFA were run at a flow rate of 1.0 mL/min over a period of 30 min. HPLCs were run on a HP1090 using a Rainin 4.6 x 250 mm C18 column (cat # 83-201-C) fluorescent detection using 350 and 500 nm as excitation and emission wavelengths, respectively. Levels of hydrolysis were determined by measuring the area of the fluorescent peak at 5.3 min. 100% hydrolysis of a 5.0 μM sample gave an area of 7.95 ±0.38 fluorescence units.). Kinetic constants were determined from the iterative fit of the Michaelis equation to the data. Results are consistent with data from Liveweaver Burk fits and data collected for the 12.8 min peak measured at 520 nm.

Enzyme activity was also measured by measuring the increase in fluorescence with time by exciting at 355 nm and measuring emission at 495 nm using a Perkin Elmer LS 50 spectrometer. A substrate level of 5.0 μM was used for all fluorogenic assays run on the spectrometer.
Inhibitor Evaluation In vitro

Inhibitor effectiveness was determined by measuring enzyme activity both in the presence and absence of inhibitor. Velocities were fit to the equation for competitive inhibition for individual reactions of inhibitors with the enzyme using

\[ \frac{v_i}{V_i} = \frac{[K_m \left(1 + \frac{I}{K_i}\right) + S]}{[K_m + S]} \]

The ratio \( \frac{v_i}{V_i} \) is equal to the ratio of the Michaelis equations for velocities measured in the presence \( (v_i) \) and absence \( (V_o) \) of inhibitor. Values of \( \frac{v_i}{V_i} \) were measured over a range of inhibitor concentrations with the aid of an Excel™ Spreadsheet. Reported \( K_i \) values are the average of 3-5 separate determinations. Under the conditions of this assay, the \( IC_{50} \) and \( K_i \)s are comparable measures of inhibitor effectiveness.

Using the methodology described above, a number of compounds of the present invention were found to exhibit a \( K_i \) of \( \leq 60 \) μM, thereby confirming the utility of the compounds of the present invention as effective NS3 protease inhibitors.

Inhibitor Evaluation in Cell Assay.

The following method was devised to assess inhibitory action of test compounds on the HCV NS3 protease in cultured cells. Because it is not possible to efficiently infect cells with hepatitis C virus, an assay was developed based on co-expression in transfected cell lines of two plasmids, one is able to direct synthesis of the NS3 protease and the other to provide a polypeptide analogous to a part of the HCV non-structural protein containing a single known peptide sequence highly susceptible to cleavage by the protease. When installed in cultured cells by one of a variety of standard methods, the substrate plasmid produces a stable polypeptide of approximately 50KD, but when the plasmid coding for the viral protease is co-expressed, the enzymatic action of the protease hydrolyzes the substrate at a unique sequence between a
cysteine and a serine pair, yielding products which can be
detected by antibody-based technology, eg, a western blot.
Quantitation of the amounts of precursor and products can
be done by scanning film auto-radiograms of the blots or
direct luminescence-based emissions from the blots in a
commercial scanning device. The general organization of the
two plasmids is disclosed in a PCT application
PCT/US00/18655. The disclosure of which is hereby
incorporated by reference. The coding sequences for the
NS3 protease and the substrate were taken from genotype 1a
of HCV, but other genotypes, eg 2a, may be substituted with
similar results.

The DNA plasmids are introduced into cultured cells
using electroporation, liposomes or other means. Synthesis
of the protease and the substrate begin shortly after
introduction and may be detected within a few hours by
immunological means. Therefore, test compounds are added at
desired concentrations to the cells within a few minutes
after introducing the plasmids. The cells are then placed
in a standard CO₂ incubator at 37°C, in tissue culture
medium eg Dulbecco-modified MEM containing 10% bovine
serum. After 6-48 hours, the cells are collected by
physically scraping them from plastic dishes in which they
have been growing, centrifuging them and then lysing about
10⁶ of the concentrated cells in a minimal volume of
buffered detergent, eg 20 µL of 1% sodium dodecyl sulfate
in 0.10 M Tris-HCl, pH 6.5, containing 1% mercaptaethanol
and 7% glycerol. The samples are then loaded onto a
standard SDS polyacrylamide gel, the polypeptides separated
by electrophoresis, and the gel contents then
electroblotted onto nitrocellulose or other suitable paper
support, and the substrate and products detected by
decoration with specific antibodies.

**DOSAGE AND FORMULATION**

The HCV protease inhibitor compounds of this invention
can be administered as treatment for the control or
prevention of hepatitis C virus infections by any means
that produces contact of the active agent with the agent’s
site of action, i.e., the NS3 protease, in the body of a
mammal. It can be administered by any conventional means
available for use in conjunction with pharmaceuticals, either as an individual therapeutic agent or in a combination of therapeutic agents. It can be administered alone, but preferably is administered with a pharmaceutical carrier selected on the basis of the chosen route of administration and standard pharmaceutical practice.

The compounds of the present invention can be administered in such oral dosage forms as tablets, capsules (each of which includes sustained release or timed release formulations), pills, powders, granules, elixirs, tinctures, suspensions, syrups, and emulsions. Likewise, they may also be administered in intravenous (bolus or infusion), intraperitoneal, subcutaneous, or intramuscular form, all using dosage forms well known to those of ordinary skill in the pharmaceutical arts.

The dosage administered will, of course, vary depending upon known factors, such as the pharmacodynamic characteristics of the particular agent and its mode and route of administration; the age, health and weight of the recipient; the nature and extent of the symptoms; the kind of concurrent treatment; the frequency of treatment; and the effect desired. By way of general guidance, a daily dosage of active ingredient can be expected to be about 0.001 to about 1000 milligrams per kilogram of body weight, with the preferred dose being about 0.01 to about 100 mg/kg; with the more preferred dose being about 0.1 to about 30 mg/kg. Advantageously, compounds of the present invention may be administered in a single daily dose, or the total daily dosage may be administered in divided doses of two, three, or four times daily.

Dosage forms of compositions suitable for administration contain from about 1 mg to about 100 mg of active ingredient per unit. In these pharmaceutical compositions the active ingredient will ordinarily be present in an amount of about 0.5-95% by weight based on the total weight of the composition. The active ingredient can be administered orally in solid dosage forms, such as
capsules, tablets and powders, or in liquid dosage forms, such as elixirs, syrups and suspensions. It can also be administered parenterally, in sterile liquid dosage forms.

Gelatin capsules contain the active ingredient and powdered carriers, such as lactose, starch, cellulose derivatives, magnesium stearate, stearic acid, and the like. Similar diluents can be used to make compressed tablets. Both tablets and capsules can be manufactured as sustained release products to provide for continuous release of medication over a period of hours. Compressed tablets can be sugar coated or film coated to mask any unpleasant taste and protect the tablet from the atmosphere, or enteric coated for selective disintegration in the gastrointestinal tract. Liquid dosage forms for oral administration can contain coloring and flavoring to increase patient acceptance.

In general, water, a suitable oil, saline, aqueous dextrose (glucose), and related sugar solutions and glycols such as propylene glycol or polyethylene glycols are suitable carriers for parenteral solutions. Solutions for parenteral administration preferably contain a water soluble salt of the active ingredient, suitable stabilizing agents, and if necessary, buffer substances. Antioxidizing agents such as sodium bisulfite, sodium sulfite, or ascorbic acid, either alone or combined, are suitable stabilizing agents. Also used are citric acid and its salts, and sodium EDTA. In addition, parenteral solutions can contain preservatives, such as benzalkonium chloride, methyl- or propyl-paraben and chlorobutanol. Suitable pharmaceutical carriers are described in Remington’s Pharmaceutical Sciences, supra, a standard reference text in this field.

Useful pharmaceutical dosage-forms for administration of the compounds of this invention can be illustrated as follows:

Capsules
A large number of unit capsules can be prepared by filling standard two-piece hard gelatin capsules each with 100 mg of powdered active ingredient, 150 mg of lactose, 50 mg of cellulose, and 6 mg magnesium stearic.

**Soft Gelatin Capsules**

A mixture of active ingredient in a digestible oil such as soybean oil, cottonseed oil or olive oil can be prepared and injected by means of a positive displacement pump into gelatin to form soft gelatin capsules containing 100 mg of the active ingredient. The capsules should then be washed and dried.

**Tablets**

A large number of tablets can be prepared by conventional procedures so that the dosage unit is 100 mg of active ingredient, 0.2 mg of colloidal silicon dioxide, 5 milligrams of magnesium stearate, 275 mg of microcrystalline cellulose, 11 mg of starch and 98.8 mg of lactose. Appropriate coatings may be applied to increase palatability or delay absorption.

**Suspension**

An aqueous suspension can be prepared for oral administration so that each 5 ml contain 25 mg of finely divided active ingredient, 200 mg of sodium carboxymethyl cellulose, 5 mg of sodium benzoate, 1.0 g of sorbitol solution, U.S.P., and 0.025 mg of vanillin.

**Injectable**

A parenteral composition suitable for administration by injection can be prepared by stirring 1.5% by weight of active ingredient in 10% by volume propylene glycol and water. The solution is sterilized by commonly used techniques.
