US 2022/0139958 A1 May 5, 2022

**Related U.S. Application Data**

A microelectronic device comprises a first set of tiers, each tier of the first set of tiers comprising alternating levels of a conductive material and an insulative material and having a first tier pitch, a second set of tiers adjacent to the first set of tiers, each tier of the second set of tiers comprising alternating levels of the conductive material and the insulative material and having a second tier pitch less than the first tier pitch, a third set of tiers adjacent to the second set of tiers, each tier of the third set of tiers comprising alternating levels of the conductive material and the insulative material and having a third tier pitch less than the second tier pitch, and a string of memory cells extending through the first set of tiers, the second set of tiers, and the third set of tiers. Related microelectronic devices, electronic systems, and methods are also described.

# MICROELECTRONIC DEVICES INCLUDING VARYING TIER PITCH, AND RELATED ELECTRONIC SYSTEMS

## CROSS-REFERENCE TO RELATED APPLICATION

This application is a continuation of U.S. patent application Ser. No. 16/904,317, filed Jun. 17, 2020, now U.S. Pat. No. 11,264,404, issued Mar. 1, 2022, the disclosure of which is hereby incorporated herein in its entirety by this reference.

## TECHNICAL FIELD

The disclosure, in various embodiments, relates generally to the field of microelectronic device design and fabrication. More specifically, the disclosure relates to microelectronic devices and apparatuses including tiers of alternating levels of insulative structures and conductive structures exhibiting a different tier pitch, and to related electronic systems and methods of forming the microelectronic devices.

## BACKGROUND

A continuing goal of the microelectronics industry has been to increase the memory density (e.g., the number of memory cells per memory die) of memory devices, such as non-volatile memory devices (e.g., NAND Flash memory devices). One way of increasing memory density in non-volatile memory devices is to utilize vertical memory array (also referred to as a “three-dimensional (3D) memory array”) architectures. A conventional vertical memory array includes vertical memory strings extending through openings in a stack of tiers of conductive structures (e.g., word lines) and dielectric materials at each junction of the vertical memory strings and the conductive structures. Such a configuration permits a greater number of switching devices (e.g., transistors) to be located in a unit of die area (i.e., length and width of active surface consumed) by building the array upwards (e.g., longitudinally, vertically) on a die, as compared to structures with conventional planar (e.g., two-dimensional) arrangements of transistors.

Conventional vertical memory arrays include electrical connections between the conductive structures and access lines (e.g., the word lines) so that memory cells in the vertical memory array can be uniquely selected for writing, reading, or erasing operations. One method of forming such an electrical connection includes forming so-called at least one “staircase” (or “stair step”) structure at edges (e.g., horizontal ends) of the tiers of conductive structures. The staircase structure includes individual “steps” providing contact regions of the conductive structures upon which conductive contact structures can be positioned to provide electrical access to the conductive structures.

As vertical memory array technology has advanced, additional memory density has been provided by forming vertical memory arrays to include stacks comprising additional tiers of conductive structures and, hence, additional staircase structures and/or additional steps in individual staircase structures associated therewith. However, increasing the quantity of tiers of conductive structures can result in a larger height of the stack and relatively large aspect ratio in openings in which the vertical memory strings are formed. Due to the large aspect ratio and the height of the stack of tiers, dielectric materials and the conductive structures may

collapse during one or more fabrication processes associated with forming the vertical memory strings.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1A is a simplified cross-sectional view of a microelectronic device structure, in accordance with embodiments of the disclosure;

FIG. 1B through FIG. 1D are simplified cross-sectional views of a memory cell of a microelectronic device, in accordance with embodiments of the disclosure;

FIG. 2A through FIG. 2C are simplified cross-sectional views illustrating a method of forming a microelectronic device structure, in accordance with embodiments of the disclosure;

FIG. 3 is a graph illustrating electrical properties and operating characteristics of triple level memory cells, in accordance with embodiments of the disclosure;

FIG. 4 is a block diagram of an electronic system, in accordance with embodiments of the disclosure; and

FIG. 5 is a processor-based system, in accordance with embodiments of the disclosure.

## DETAILED DESCRIPTION

The illustrations included herewith are not meant to be actual views of any particular systems, microelectronic structures, microelectronic devices, or integrated circuits thereof, but are merely idealized representations that are employed to describe embodiments herein. Elements and features common between figures may retain the same numerical designation except that, for ease of following the description, reference numerals begin with the number of the drawing on which the elements are introduced or most fully described.

The following description provides specific details, such as material types, material thicknesses, and processing conditions in order to provide a thorough description of embodiments described herein. However, a person of ordinary skill in the art will understand that the embodiments disclosed herein may be practiced without employing these specific details. Indeed, the embodiments may be practiced in conjunction with conventional fabrication techniques employed in the semiconductor industry. In addition, the description provided herein does not form a complete process flow for manufacturing a microelectronic device (e.g., a semiconductor device, a memory device, such as DRAM memory device), apparatus, or electronic system, or a complete microelectronic device, apparatus, or electronic system including a varying tier pitch. The structures described below do not form a complete microelectronic device, apparatus, or electronic system. Only those process acts and structures necessary to understand the embodiments described herein are described in detail below. Additional acts to form a complete microelectronic device, apparatus, or electronic system from the structures may be performed by conventional techniques.

The materials described herein may be formed by conventional techniques including, but not limited to, spin coating, blanket coating, chemical vapor deposition (CVD), atomic layer deposition (ALD), plasma enhanced ALD, physical vapor deposition (PVD), plasma enhanced chemical vapor deposition (PECVD), or low pressure chemical vapor deposition (LPCVD). Alternatively, the materials may be grown in situ. Depending on the specific material to be formed, the technique for depositing or growing the material may be selected by a person of ordinary skill in the art. The

removal of materials may be accomplished by any suitable technique including, but not limited to, etching, abrasive planarization (e.g., chemical-mechanical planarization), or other known methods unless the context indicates otherwise.

As used herein, the terms “longitudinal,” “vertical,” “lateral,” and “horizontal” are in reference to a major plane of a substrate (e.g., base material, base structure, base construction, etc.) in or on which one or more structures and/or features are formed and are not necessarily defined by Earth’s gravitational field. A “lateral” or “horizontal” direction is a direction that is substantially parallel to the major plane of the substrate, while a “longitudinal” or “vertical” direction is a direction that is substantially perpendicular to the major plane of the substrate. The major plane of the substrate is defined by a surface of the substrate having a relatively large area compared to other surfaces of the substrate.

As used herein, the term “substantially” in reference to a given parameter, property, or condition means and includes to a degree that one of ordinary skill in the art would understand that the given parameter, property, or condition is met with a degree of variance, such as within acceptable tolerances. By way of example, depending on the particular parameter, property, or condition that is substantially met, the parameter, property, or condition may be at least 90.0 percent met, at least 95.0 percent met, at least 99.0 percent met, at least 99.9 percent met, or even 100.0 percent met.

As used herein, “about” or “approximately” in reference to a numerical value for a particular parameter is inclusive of the numerical value and a degree of variance from the numerical value that one of ordinary skill in the art would understand is within acceptable tolerances for the particular parameter. For example, “about” or “approximately” in reference to a numerical value may include additional numerical values within a range of from 90.0 percent to 110.0 percent of the numerical value, such as within a range of from 95.0 percent to 105.0 percent of the numerical value, within a range of from 97.5 percent to 102.5 percent of the numerical value, within a range of from 99.0 percent to 101.0 percent of the numerical value, within a range of from 99.5 percent to 100.5 percent of the numerical value, or within a range of from 99.9 percent to 100.1 percent of the numerical value.

As used herein, spatially relative terms, such as “beneath,” “below,” “lower,” “bottom,” “above,” “upper,” “top,” “front,” “rear,” “left,” “right,” and the like, may be used for ease of description to describe one element’s or feature’s relationship to another element(s) or feature(s) as illustrated in the figures. Unless otherwise specified, the spatially relative terms are intended to encompass different orientations of the materials in addition to the orientation depicted in the figures. For example, if materials in the figures are inverted, elements described as “below” or “beneath” or “under” or “on bottom of” other elements or features would then be oriented “above” or “on top of” the other elements or features. Thus, the term “below” can encompass both an orientation of above and below, depending on the context in which the term is used, which will be evident to one of ordinary skill in the art. The materials may be otherwise oriented (e.g., rotated 90 degrees, inverted, flipped, etc.) and the spatially relative descriptors used herein interpreted accordingly.

As used herein, the term “memory device” means and includes microelectronic devices exhibiting memory functionality, but not necessarily limited to memory functionality. Stated another way, and by way of example only, the term “memory device” means and includes not only con-

ventional memory in the form of DRAM, NAND, etc., but also by way of example only, an application specific integrated circuit (ASIC) (e.g., a system on a chip (SoC)), a microelectronic device combining logic and memory, or a graphics processing unit (GPU) incorporating memory.

As used herein, the term “tier pitch” means and includes a distance between a feature of a tier and a similar, corresponding feature of an adjacent tier. The terms “tier pitch” and “tier thickness” may be used interchangeably herein.

According to embodiments described herein, a microelectronic device comprises a stack structure on or over a base structure such as a source structure. The stack structure may include vertically alternating insulative materials and conductive materials arranged in tiers. Each tier may individually include an insulative material vertically adjacent a conductive material. Different tiers of the stack structure may have a different thickness (e.g., in the vertical direction) depending on a depth of the respective tier from an upper surface of the microelectronic device (or, similarly, depending on a distance of the respective tier from the base structure). In some embodiments, the stack structure includes a first deck structure adjacent to (e.g., over) the base structure, an interdeck structure adjacent to (e.g., over) the first deck structure, and a second deck structure adjacent to (e.g., over) the interdeck structure. The first deck structure may include a first region of tiers adjacent to (e.g., over) the base structure, a second region of tiers adjacent to (e.g., over) the first region, and a third region of tiers adjacent to (e.g., over) the second region of tiers. A tier pitch of the tiers of the first region may be greater than the tier pitch of each of the tiers of the second region and the tiers of the third region. Accordingly, tiers of the first region may have a greater thickness than the tiers of each of the second region and the third region. In some such embodiments, at least the levels of the insulative materials of the first region may have a greater thickness than the levels of the insulative materials of each of the second region and the third region. In addition, a tier pitch of the tiers of the second region may be larger than the tier pitch of the tiers of the third region. In some such embodiments, at least the levels of the insulative materials of the second region may have a greater thickness than the thickness of the levels of the insulative materials of the third region.

In some embodiments, the second deck structure includes a fourth region of tiers adjacent to (e.g., over) the interdeck structure, a fifth region of tiers adjacent to (e.g., over) the fourth region of tiers, and a sixth region of tiers adjacent to (e.g., over) the fifth region of tiers. A tier pitch of the tiers of each of the fourth region, the fifth region, and the sixth region may be different. In some embodiments, the tier pitch of the fourth region may be greater than the tier pitch of the fifth region. The tier pitch of the sixth region may be greater than the tier pitch of the fourth region and the fifth region.

Strings of memory cells may extend through the stack structure, memory cells being located at intersections between the conductive materials and pillar structures (e.g., semiconductive pillars) vertically extending through the stack structure forming strings of memory cells. Dimensions of the memory cells may vary depending on the location of the memory cells within the string (e.g., whether the memory cells are located within the first region, the second region, the third region, the fourth region, the first region, or the sixth region). For example, the memory cells within the second region may be spaced farther from each other than the memory cells of the third region. In some embodiments, the first region may not include any triple level cells, while the second region, the third region, the fourth region, and the

fifth region include triple level cells. Accordingly, in some embodiments, regions including a relatively greater tier pitch may not include triple level cells.

The greater thickness of the insulative materials of the first region and the second region may facilitate improved fabrication of the microelectronic device structure. For example, the greater tier pitch (and corresponding greater thickness of the insulative materials) of the first region and the second region relative to the tier pitch of the third region may facilitate performance of a so-called “replacement gate” process wherein sacrificial materials are removed from tiers and replaced with the conductive materials to form the tiers of the insulative materials and the conductive materials. After removal of the sacrificial materials, the insulative materials may exhibit a reduced tendency to collapse or topple, due to the increased thickness of the insulative materials (and the corresponding reduction in the aspect ratio thereof). In addition, the memory cells of the second region, which are spaced farther from adjacent memory cells than the memory cells of the third region, may exhibit improved operating properties. For example, the memory cells of the second region may exhibit an improved read window budget (RWB) and a more narrow threshold voltage distribution between levels of the memory cells due, at least in part, to the increased spacing of the memory cells of the second region. In addition, the memory cells of the fourth region may exhibit a similar improvement of the read window budget and narrower threshold voltage distribution compared to the memory cells of the fifth region.

FIG. 1A is a simplified cross-sectional view of a microelectronic device 100, in accordance with embodiments of the disclosure. The microelectronic device 100 may include a stack structure 101 including a vertically (e.g., in the Z-direction) alternative sequence of insulative materials 104 and conductive materials 106 arranged in tiers 102. Each of the tiers 102 may individually include a level of the insulative materials 104 directly vertically adjacent a level of the conductive materials 106. The insulative materials 104 of the stack structure 101 may also be referred to herein as “insulative structures” and the conductive materials 106 of the stack structure 101 may also be referred to herein as “conductive structures.”

The levels of the insulative materials 104 may be formed of and include, for example, at least one dielectric material, such as one or more of an oxide material (e.g., silicon dioxide (SiO<sub>2</sub>)), phosphosilicate glass, borosilicate glass, borophosphosilicate glass, fluorosilicate glass, titanium dioxide (TiO<sub>2</sub>), hafnium oxide (HfO<sub>2</sub>), zirconium dioxide (ZrO<sub>2</sub>), hafnium dioxide (HfO<sub>2</sub>), tantalum oxide (TaO<sub>2</sub>), magnesium oxide (MgO), and aluminum oxide (Al<sub>2</sub>O<sub>3</sub>). In some embodiments, the insulative materials 104 are formed of and include silicon dioxide.

The levels of the conductive materials 106 may each comprise, for example, access lines, which may be referred to as word lines. The levels of the conductive materials 106 may be formed of and include, for example, at least one electrically conductive material, such as, for example, tungsten, titanium, nickel, cobalt, platinum, rhodium, ruthenium, iridium, aluminum, copper, molybdenum, silver, gold, a metal alloy, a metal-containing material (e.g., metal nitrides, metal silicides, metal carbides, metal oxides), a material including at least one of titanium nitride (TiN), tantalum nitride (TaN), tungsten nitride (WN), titanium aluminum nitride (TiAlN), iridium oxide (IrO<sub>x</sub>), ruthenium oxide (RuO<sub>x</sub>), alloys thereof, a conductively-doped semiconductor material (e.g., conductively-doped silicon, conductively-doped germanium, conductively-doped silicon germanium,

etc.), polysilicon, other materials exhibiting electrical conductivity, or combinations thereof. In some embodiments, the conductive materials 106 comprise tungsten. In other embodiments, the conductive materials 106 comprise polysilicon.

As shown in FIG. 1A, optionally, a conductive liner material 108 may be located around the conductive materials 106, such as between the conductive materials 106 and the insulative materials 104. The conductive liner material 108 may comprise, for example, a seed material from which the conductive material 106 may be formed. The conductive liner material 108 may be formed of and include, for example, a metal (e.g., titanium, tantalum), a metal nitride (e.g., tungsten nitride, titanium nitride, tantalum nitride), or another material. In some embodiments, the conductive liner material 108 comprises titanium nitride. However, in some embodiments, the microelectronic device 100 does not include the conductive liner material 108 and the conductive materials 106 are directly adjacent to and physically contact the insulative materials 104. By way of non-limiting example, in some embodiments, the conductive material 106 comprises polysilicon and the microelectronic device 100 does not include the conductive liner material 108.

The stack structure 101 may be formed over a source material 107. The source material 107 may be formed of and include, for example, a semiconductor material doped with one of P-type conductivity materials (e.g., polysilicon doped with at least one P-type dopant (e.g., boron ions)) or N-type conductivity materials (e.g., polysilicon doped with at least one N-type dopant (e.g., arsenic ions, phosphorous ions, antimony ions)).

The stack structure may include a stair step region 103 and a memory cell region 105. The stair step region 103 may include at least one staircase structure 195 including steps 109 defined by horizontal ends of at least some of the tiers 102 of the stack structure 101. In some embodiments, each step 109 of the staircase structure 195 may be defined by horizontal ends of one insulative material 104 and one conductive material 106. However, the disclosure is not so limited and the steps 109 may be defined by more than one of the insulative materials 104 and one of the conductive materials 106.

Strings 110 of memory cells 112 may vertically extend (e.g., in the Z-direction) through the stack structure 101. The strings 110 of memory cells 112 may each individually comprise multiple memory cells 112 substantially horizontally aligned with one another within the stack structure 101. Box B illustrates a memory cell 112, in accordance with some embodiments of the disclosure. Adjacent strings 110 of memory cells 112 may be separated from each other by, for example, pillars of an insulative material 190.

FIG. 1B is a simplified blown up view of box B of FIG. 1A illustrating a memory cell 112, in accordance with embodiments of the disclosure. With reference to FIG. 1A and FIG. 1B, each memory cell 112 may include an insulative material 114, a channel material 116 horizontally adjacent to the insulative material 114, a tunnel dielectric material (also referred to as a “tunneling dielectric material”) 118 horizontally adjacent to the channel material 116, a memory material 120 horizontally adjacent to the tunnel dielectric material 118, a dielectric blocking material (also referred to as a “charge blocking material”) 122 horizontally adjacent to the memory material 120, and a dielectric barrier material 124 horizontally adjacent to the dielectric blocking material 122. The dielectric barrier material 124 may be horizontally adjacent to one of the levels of conductive materials 106 of one of the tiers 102 of the stack structure

101. In some embodiments, and with reference to FIG. 1B, the dielectric barrier material **124** may be disposed around the conductive material **106**. In other embodiments, and with reference to FIG. 1A, the dielectric barrier material **124** may extend vertically through the string **110**. The channel material **116** may be horizontally interposed between the insulative material **114** and the tunnel dielectric material **118**; the tunnel dielectric material **118** may be horizontally interposed between the channel material **116** and the memory material **120**; the memory material **120** may be horizontally interposed between the tunnel dielectric material **118** and the dielectric blocking material **122**; the dielectric blocking material **122** may be horizontally interposed between the memory material **120** and the dielectric barrier material **124**; and the dielectric barrier material **124** may be horizontally interposed between the dielectric blocking material **122** and the level of conductive material **106**.

Each of the memory cells **112** may be located at an intersection of a conductive material **106** of one of the tiers **102** of the stack structure **101** and a pillar structure vertically extending through the stack structure **101** and including the insulative material **114**, the channel material **116**, the tunnel dielectric material **118**, the memory material **120**, the dielectric blocking material **122**, and the dielectric barrier material **124**.

The insulative material **114** may be formed of and include an electrically insulative material such as, for example, phosphosilicate glass (PSG), borosilicate glass (BSG), fluorosilicate glass (FSG), borophosphosilicate glass (BPSG), silicon dioxide, titanium dioxide, zirconium dioxide, hafnium dioxide, tantalum oxide, magnesium oxide, aluminum oxide, niobium oxide, molybdenum oxide, strontium oxide, barium oxide, yttrium oxide, a nitride material, (e.g., silicon nitride ( $\text{Si}_3\text{N}_4$ )), an oxynitride (e.g., silicon oxynitride), a dielectric carbon nitride material (e.g., silicon carbon nitride ( $\text{SiCN}$ )), a dielectric carboxynitride material (e.g., silicon carboxynitride ( $\text{SiOCN}$ )), or combinations thereof. In some embodiments, the insulative material **114** comprises silicon dioxide.

The channel material **116** may be formed of and include one or more of a semiconductor material (at least one elemental semiconductor material, such as polycrystalline silicon; at least one III-V compound semiconductor material, at least one II-VI compound semiconductor material, at least one organic semiconductor material, GaAs, InP, GaP, GaN, other semiconductor materials), and an oxide semiconductor material. In some embodiments, the channel material **116** includes amorphous silicon or polysilicon. In some embodiments, the channel material **116** comprises a doped semiconductor material.

The tunnel dielectric material **118** may be formed of and include a dielectric material through which charge tunneling can be performed under suitable electrical bias conditions, such as through hot-carrier injection or by Fowler-Nordheim tunneling induced charge transfer. The tunnel dielectric material **118** may be formed of and include one or more of silicon oxide, silicon nitride, silicon oxynitride, dielectric metal oxides (such as aluminum oxide and hafnium oxide), dielectric metal oxynitride, dielectric metal silicates, alloys thereof, and/or combinations thereof. In some embodiments, the tunnel dielectric material **118** comprises silicon dioxide or silicon oxynitride.

The memory material **120** may comprise a charge trapping material or a conductive material. The memory material **120** may be formed of and include one or more of silicon nitride, silicon oxynitride, polysilicon (doped polysilicon), a conductive material (tungsten, molybdenum, tantalum, tita-

niun, platinum, ruthenium, and alloys thereof, or a metal silicide such as tungsten silicide, molybdenum silicide, tantalum silicide, titanium silicide, nickel silicide, cobalt silicide, or a combination thereof), a semiconductor material polycrystalline or amorphous semiconductor material including at least one elemental semiconductor element or at least one compound semiconductor material, conductive nanoparticles (e.g., ruthenium nanoparticles), metal dots. In some embodiments, the memory material **120** comprises silicon nitride.

The dielectric blocking material **122** may be formed of and include a dielectric material such as, for example, one or more of an oxide (e.g., silicon dioxide), a nitride (silicon nitride), and an oxynitride (silicon oxynitride), or another material. In some embodiments, the dielectric blocking material **122** comprises silicon oxynitride.

In some embodiments the tunnel dielectric material **118**, the memory material **120**, and the dielectric blocking material **122** together may form comprise a structure configured to trap a charge, such as, for example, an oxide-nitride-oxide (ONO) structure. In some such embodiments, the tunnel dielectric material **118** comprises silicon dioxide, the memory material **120** comprises silicon nitride, and the dielectric blocking material **122** comprises silicon dioxide.

The dielectric barrier material **124** may be formed of and include one or more of a metal oxide (e.g., one or more of aluminum oxide, hafnium oxide, zirconium oxide, lanthanum oxide, yttrium oxide, tantalum oxide, gadolinium oxide, niobium oxide, titanium oxide), a dielectric silicide (e.g., aluminum silicide, hafnium silicate, zirconium silicate, lanthanum silicide, yttrium silicide, tantalum silicide), and a dielectric nitride (e.g., aluminum nitride, hafnium nitride, lanthanum nitride, yttrium nitride, tantalum nitride). In some embodiments, the dielectric barrier material **124** comprises aluminum oxide.

Although the memory cells **112** of FIG. 1A and FIG. 1B have been described and illustrated as having a particular structure and composition, the disclosure is not so limited. FIG. 1C is a simplified cross-sectional view of a memory cell **112'**, in accordance with embodiments of the disclosure. One or more of (e.g., all of) the memory cells **112** of FIG. 1A may be replaced with the memory cell **112'**. With reference to FIG. 1C, the memory cell **112'** may include the insulative material **114** and the channel material **116** as described above with reference to the memory cells **112**. The memory cell **112'** may further include a first dielectric material (e.g., a tunnel dielectric material) **160** horizontally adjacent to the channel material **116**, a second dielectric material (e.g., a charge trapping material) **162** horizontally adjacent to the first dielectric material **160**, and a third dielectric material (e.g., a charge blocking material) **164** horizontally adjacent to the second dielectric material **162** and the conductive material **106**. In some embodiments, the first dielectric material comprises an oxide material (e.g., silicon dioxide), the second dielectric material comprises a nitride material (e.g., silicon nitride), and the third dielectric material **164** comprises an oxide material (e.g., silicon dioxide). For clarity, in FIG. 1C, the conductive liner material **108** (FIG. 1A, FIG. 1B) is not illustrated around the conductive material **106**. However, it will be understood that in some embodiments, the memory cell **112'** may include the conductive liner material **108**.

FIG. 1D is a simplified cross-sectional view of a memory cell **112''**, in accordance with additional embodiments of the disclosure. The memory cell **112''** may include the insulative material **114** and the channel material **116**. In some embodiments, the memory cell **112''** may comprise a so-called

“floating gate” memory cell. The memory cell **112** may include an electrode structure **170**, which may be referred to as a “floating gate.” The electrode structure **170** may comprise an electrically conductive material, such as, for example, one or more of the materials described above with reference to the conductive materials **106**. In some embodiments, the electrode structure **170** comprises polysilicon. In other embodiments, the electrode structure **170** comprises tungsten.

With continued reference to FIG. 1D, the memory cell **112** may further include a dielectric material **172**, which may be referred to as a “gate dielectric” material. The dielectric material **172** may comprise, for example, one or more of the materials described above with reference to the tunnel dielectric material **118**. In some embodiments, the dielectric material **172** comprises silicon dioxide. An other dielectric material **174** may be located around portions of the electrode structure **170**. The other dielectric material **174** may comprise one or more of the materials described above with reference to the tunnel dielectric material **118**. In some embodiments, the other dielectric material **174** has the same material composition as the dielectric material **172**. The other dielectric material **174** may be located between the electrode structure **170** and the conductive material **106**. For clarity, in FIG. 1D, the conductive liner material **108** (FIG. 1A, FIG. 1B) is not illustrated around the conductive material **106**. However, it will be understood that in some embodiments, the memory cell **112** may include the conductive liner material **108**.

Referring back to FIG. 1A, the stack structure **101** may include a first deck structure **130** vertically overlying the source material **107**, an interdeck structure **150** vertically overlying the first deck structure **130**, and a second deck structure **140** vertically overlying the interdeck structure **150**.

The first deck structure **130** may include a first region **132** of tiers **102** vertically overlying the source material **107**, a second region **134** of tiers **102** vertically overlying the first region **132**, and a third region **136** of tiers **102** vertically overlying the second region **134**. A tier pitch of the tiers **102** in the first region **132** may be different than a tier pitch of the tiers **102** of each of the second region **134** and the third region **136**. In addition, the tier pitch of the second region **134** may be different than the tier pitch of the third region **136**. In some embodiments, the tier pitch of the first region **132** is larger than the tier pitch of each of the second region **134** and the third region **136** and the tier pitch of the second region is larger than the tier pitch of the third region **136**.

In some embodiments, a number (e.g., quantity) of tiers **102** of the first deck structure **130** may be within a range from about 64 of the tiers **102** to about 256 of the tiers **102**. In some embodiments, the first deck structure **130** includes 128 tiers **102**. However, the disclosure is not so limited, and the first deck structure **130** may include a different number of the tiers **102**.

A number of tiers **102** of the first region **132** may be from about 1 of the tiers **102** to about 20 of the tiers **102**, such as from 1 of the tiers **102** to 4 of the tiers **102**, from 4 of the tiers **102** to 8 of the tiers **102**, from 8 of the tiers **102** to 12 of the tiers **102**, or from 12 of the tiers **102** to 20 of the tiers **102**. In some embodiments, the first region **132** includes 8 of the tiers **102**.

For each tier **102** within the first region **132** of the first deck structure **130**, the insulative material **104** may have a thickness (in the z-direction)  $T_1$ , and the conductive material **106** and conductive liner material **108** may have a combined thickness (in the z-direction)  $T_2$ . As used herein, the thick-

ness  $T_2$  of the conductive material **106** means and includes the combined thickness of the conductive material **106** and the conductive liner material **108**, if present. Stated another way, the thickness  $T_2$  defines a distance or spacing between adjacent insulative materials **104** in the first region **132**. In some embodiments, the thickness  $T_1$  of the insulative material **104** and the thickness  $T_2$  comprise a total thickness of each tier **102**. In some embodiments, the thickness  $T_1$  of the insulative material **104** and the thickness  $T_2$  comprise a total thickness of each tier **102** within the first region **132**. Accordingly, the tier pitch of the tiers **102** of the first region **132** comprises the sum of the thicknesses  $T_1$ ,  $T_2$ .

The thickness  $T_1$  of the insulative material **104** of each of the tiers **102** within the first region **132** may be within a range from about 20 nanometers (nm) to about 30 nm, such as from about 20 nm to about 22 nm, from about 22 nm to about 24 nm, from about 24 nm to about 26 nm, from about 26 nm to about 28 nm, or from about 28 nm to about 30 nm. In some embodiments, the thickness  $T_1$  is from about 21 nm to about 25 nm. In some embodiments, the thickness  $T_1$  is about 23 nm.

The thickness  $T_2$  of the conductive materials **106** of each of the tiers **102** within the first region **132** may be within a range from about 25 nm to about 35 nm, such as from about 25 nm to about 27 nm, from about 27 nm to about 29, from about 29 nm to about 31 nm, from about 31 nm to about 33 nm, or from about 33 nm to about 35 nm. In some embodiments, the thickness  $T_2$  is from about 28 nm to about 32 nm. In some embodiments, the thickness  $T_2$  is about 30 nm. In some embodiments, the thickness  $T_2$  may be greater than the thickness  $T_1$ .

In some embodiments, a thickness of the tiers **102** within the first region **132** is substantially uniform. In other words, a thickness between one tier **102** of the first region **132** may not substantially vary from a thickness of other tiers **102** of the first region **132**. Stated another way, the tier pitch within the first region **132** may not substantially vary between the tiers **102** of the first region **132**.

The tiers **102** of the first region **132** may include conductive materials **106** that comprise one or more of select gate structures (e.g., select gate source (SGS) structures), dummy word lines, and word lines for memory cells **112** comprising single level cells (SLCs). In some embodiments, at least some of the conductive materials **106** comprise dummy word lines and are not associated with a memory cell **112** storing data.

In some embodiments, about one half of the tiers **102** of the first region **132** include conductive materials **106** comprising select gate structures, the remaining tiers **102** including conductive materials **106** that comprise word lines of dummy tiers **102** or word lines of a single level cell. In some embodiments, the first region **132** includes 4 tiers **102** comprising select gate structures, 3 dummy tiers **102**, and one tier **102** including a single level cell.

The second region **134** of the first deck structure **130** may include memory cells **112** that comprise multi-level cells (MLCs), such as, for example, triple level cells (TLCs). In some embodiments, the memory cells **112** associated with the second region **134** may include triple level memory cells. In some embodiments, substantially all of the memory cells **112** within the second region **134** comprise triple level cells. In some such embodiments, the conductive materials **106** of the second region **134** may each form a part of (e.g., a word line of) a memory cell **112** comprising a triple level cell.

The second region **134** may include from 10 of the tiers **102** to 30 of the tiers **102**, such as from 10 of the tiers **102** to 15 of the tiers **102**, from 15 of the tiers **102** to 20 of the

tiers 102, from 20 of the tiers 102 to 25 of the tiers 102, or from 25 of the tiers 102 to 30 of the tiers 102. In some embodiments, the second region 134 includes from 10 of the tiers 102 to 14 of the tiers 102. In some embodiments, the second region 134 includes 12 of the tiers 102.

For each tier 102 within the second region 134 of the first deck structure 130, the insulative material 104 may have a thickness (in the z-direction)  $T_3$ , and the conductive material 106 and conductive liner material 108 may have a thickness (in the z-direction)  $T_4$ . As used herein, the thickness  $T_4$  of the conductive material 106 means and includes the combined thickness of the conductive material 106 and the conductive liner material 108, if present. In other words, the thickness  $T_4$  corresponds to the spacing between insulative materials 104 of the second region 134. In some embodiments, the thickness  $T_3$  of the insulative material 104 and the thickness  $T_4$  comprise a total thickness of each tier 102 within the second region 134. Accordingly, the tier pitch of the second region 134 may correspond to the sum of the thicknesses  $T_3$ ,  $T_4$ . In some embodiments, the tier pitch of the second region 134 is less than the tier pitch of the first region 132.

The thickness  $T_3$  of the insulative material 104 of each of the tiers 102 within the second region 134 may be within a range from about 18 nm to about 28 nm, such as from about 18 nm to about 20 nm, from about 20 nm to about 22 nm, from about 22 nm to about 24 nm, from about 24 nm to about 26 nm, or from about 26 nm to about 28 nm. In some embodiments, the thickness  $T_3$  is from about 20 nm to about 24 nm. In some embodiments, the thickness  $T_3$  is about 22 nm. In some embodiments, the thickness  $T_3$  of the insulative materials 104 within the second region 134 is less than the thickness  $T_1$  of the insulative materials 104 within the first region 132.

The thickness  $T_1$  of the insulative material 104 of each of the tiers 102 of the first region 132 may be within a range of from about one percent to about ten percent greater than the thickness  $T_3$  of the insulative material 104 of each of the tiers 102 of the second region 134, such as from about one percent to about two percent, from about two percent to about five percent, or from about five percent to about ten percent greater than the thickness  $T_3$ .

The thickness  $T_4$  of the conductive material 106 of each of the tiers 102 within the second region 134 may be within a range from about 24 nm to about 34 nm, such as from about 24 nm to about 26 nm, from about 26 nm to about 28 nm, from about 28 nm to about 30 nm, from about 30 nm to about 32 nm, or from about 32 nm to about 34 nm. In some embodiments, the thickness  $T_4$  is from about 27 nm to about 31 nm. In some embodiments, the thickness  $T_4$  is about 29 nm. The thickness  $T_4$  may be greater than the thickness  $T_3$ . In some embodiments, the thickness  $T_4$  of the conductive material 106 of each of the tiers 102 within the second region 134 is less than the thickness  $T_2$  of the conductive material 106 of each of the tiers 102 within the first region 132. The thickness  $T_2$  of the conductive materials 106 of the first region 132 may be within a range of from about one percent to about ten percent greater than the thickness  $T_4$  of the conductive materials 106 of the second region 134, such as from about one percent to about two percent, from about two percent to about five percent, or from about five percent to about ten percent greater than the thickness  $T_4$ .

In some embodiments, a thickness of the tiers 102 within the second region 134 is substantially uniform. In other words, a thickness between one tier 102 of the second region 134 may not substantially vary from a thickness of other

tiers 102 of the second region 134. Stated another way, the tier pitch of the tiers 102 of the second region 134 may be substantially uniform.

With continued reference to FIG. 1A, the third region 136 may include 32 of the tiers 102 to 120 of the tiers 102, such as from 32 of the tiers 102 to 64 of the tiers 102, from 64 of the tiers 102 to 80 of the tiers 102, from 80 of the tiers 102 to 96 of the tiers 102, or from 96 of the tiers 102 to 120 of the tiers 102. In some embodiments, the third region 136 includes from 100 of the tiers 102 to 110 of the tiers 102. In some embodiments, the third region 136 includes 105 of the tiers 102.

In some embodiments, a majority (e.g., all, substantially all, all but one, all but two) of the conductive materials 106 of the third region 136 may be associated with memory cells 112 comprising triple level cells. In some embodiments, some of the conductive materials 106 of the third region 136 may comprise a portion of (e.g., a word line of) a memory cell 112 comprising a multilevel cell and one of the conductive materials 106 of the third region 136 may comprise a portion of (e.g., a word line of) a dummy region. By way of non-limiting example, an uppermost tier 102 of the third region 136 may include a conductive material 106 comprising a dummy word line, a tier 102 adjacent to the uppermost tier 102 may comprise a conductive material 106 comprising a word line of a multilevel cell, and the other conductive materials 106 of the third region 136 may comprise word lines of triple level cells.

For each tier 102 within the third region 136 of the first deck structure 130, the insulative material 104 may have a thickness (in the z-direction)  $T_5$  and the conductive material 106 and conductive liner material 108 may have a thickness (in the z-direction)  $T_6$ . As used herein, the thickness  $T_6$  of the conductive material 106 means and includes the combined thickness of the conductive material 106 and the conductive liner material 108, if present. In other words, the thickness  $T_6$  corresponds to the spacing between insulative materials 104 of the third region 136. In some embodiments, the thickness  $T_5$  of the insulative material 104 and the thickness  $T_6$  comprise a total thickness of each tier 102 within the third region 136 and the sum of the thicknesses  $T_5$ ,  $T_6$  corresponds to the tier pitch of the third region 136. In some embodiments, the tier pitch of the third region 136 is less than the tier pitch of the first region 132 and the tier pitch of the second region 134.

The thickness  $T_5$  of the insulative material 104 of each of the tiers 102 within the third region 136 may be within a range from about 16 nm to about 24 nm, such as from about 16 nm to about 18 nm, from about 18 nm to about 20 nm, from about 20 nm to about 22 nm, or from about 22 nm to about 24 nm. In some embodiments, the thickness  $T_5$  is from about 18 nm to about 22 nm. In some embodiments, the thickness  $T_5$  is about 20 nm. In some embodiments, the thickness  $T_5$  of the insulative materials 104 within the third region 136 is less than the thickness  $T_3$  of the insulative materials 104 within the second region 134 or the thickness  $T_1$  of the insulative materials 104 within the first region 132.

The thickness  $T_1$  of the insulative materials 104 of each of the tiers 102 of the first region 132 may be within a range of from about one percent to about twenty percent greater than the thickness  $T_5$  of each of the tiers 102 of the insulative materials 104 of the third region 136, such as from about one percent to about two percent, from about two percent to about five percent, from about five percent to about ten percent, or from about ten percent to about twenty percent greater than the thickness  $T_5$ .

The thickness  $T_6$  of the conductive material **106** of each of the tiers **102** within the third region **136** may be within a range from about 24 nm to about 34 nm, such as from about 24 nm to about 26 nm, from about 26 nm to about 28, from about 28 nm to about 30 nm, from about 30 nm to about 32 nm, or from about 32 nm to about 34 nm. In some embodiments, the thickness  $T_6$  is from about 27 nm to about 31 nm. In some embodiments, the thickness  $T_6$  is about 29 nm. In some embodiments, the thickness  $T_6$  is the same as the thickness  $T_4$ . In some embodiments, the thickness  $T_6$  of the conductive materials **106** within the third region **136** is less than the thickness  $T_2$  of the conductive materials **106** within the first region **132**. The thickness  $T_2$  of the conductive materials **106** of the first region **132** may be within a range of from about one percent to about twenty percent greater than the thickness  $T_6$  of the conductive materials **106** of the third region **136**, such as from about one percent to about two percent, from about two percent to about five percent, from about five percent to about ten percent greater, or from about ten percent to about twenty percent greater than the thickness  $T_4$ .

In some embodiments, a thickness of the tiers **102** within the third region **136** is substantially uniform. In other words, a thickness between one tier **102** of the third region **136** may not substantially vary from a thickness of other tiers **102** of the third region **136**. Stated another way, in some embodiments, the tier pitch of the tiers **102** of the third region **136** may be substantially uniform.

In some embodiments, the tier pitch of the second region **134** is about 2 nm less than the tier pitch of the first region **132** and about 2 nm greater than tier pitch of the third region **136**. In some embodiments, the tier pitch of the first region **132** is about 53 nm, the tier pitch of the second region **134** is about 51 nm, and the tier pitch of the third region **136** is about 49 nm.

The interdeck structure **150** may be between the first deck structure **130** and the second deck structure **140**. The interdeck structure **150** may comprise, for example, a first oxide material (e.g., silicon dioxide) adjacent to (e.g., over) the first deck structure **130**, a nitride material (e.g., silicon nitride) adjacent to (e.g., over) the first oxide material, and a second oxide material (e.g., silicon dioxide) adjacent to (e.g., over) the nitride material. In some embodiments, the interdeck structure **150** comprises one or more etch stop materials, such as, for example, one or more of aluminum oxide or cerium oxide. However, the disclosure is not so limited and the interdeck structure **150** may include other materials or structures.

The second deck structure **140** may include a fourth region **142** of tiers **102** vertically overlying the interdeck structure **150**, a fifth region **144** of tiers **102** vertically overlying the fourth region **142**, and a sixth region **146** of tiers **102** vertically overlying the fifth region **144**. In some embodiments, the tier pitch of the fourth region **142** is greater than the tier pitch of the fifth region **144** and less than the tier pitch of the sixth region **146**. The tier pitch of the sixth region **146** may be larger than the tier pitch of the fifth region **144**.

In some embodiments, a number of the tiers **102** of the second deck structure **140** may be within a range from 64 of the tiers to 256 of the tiers **102**. In some embodiments, the second deck structure **140** includes 128 of the tier **102**. However, the disclosure is not so limited, and the second deck structure **140** may include a different number of the tiers **102**.

The fourth region **142** may include from 8 of the tiers **102** to 30 of the tiers **102**, such as from 8 tiers of the **102** to 12

of the tiers **102**, from 12 of the tiers **102** to 20 of the tiers **102**, or from 20 of the tiers **102** to 30 of the tiers **102**. In some embodiments, the fourth region **142** comprises 20 of the tiers.

The levels of the insulative material **104** and the conductive material **106** of the fourth region **142** may have the same thickness  $T_3$ ,  $T_4$ , respectively as the respective levels of the insulative material **104** and conductive material **106** of the second region **134** of the first deck structure **130**.

The conductive materials **106** of the tiers **102** of the fourth region **142** may be associated with one or more of memory cells **112** that are triple level cells, multilevel cells, or dummy cells. In some embodiments, a majority of the conductive materials **106** of the fourth region **142** are associated with memory cells **112** comprising triple level cells. In some embodiments, the fourth region **142** includes 20 of the tiers **102**; 3 of the tiers comprising dummy memory cells, 1 of the tiers comprising a multilevel cell, and about 16 of the tiers including triple level cells.

The fifth region **144** may include from 32 of the tiers **102** to 120 of the tiers **102**, such as from 32 of the tiers **102** to 64 of the tiers **102**, from 64 of the tiers **102** to 80 of the tiers **102**, from 80 of the tiers **102** to 96 of the tiers **102**, or from 96 of the tiers **102** to 120 of the tiers **102**. In some embodiments, the fifth region **144** includes from 95 of the tiers **102** to 105 of the tiers **102**. In some embodiments, the fifth region **144** includes 100 of the tiers **102**.

The tiers **102** of the fifth region **144** may include memory cells **112** comprising triple level cells, single level cells, or both. In other words, some of the tiers **102** of the fifth region **144** may include triple level cells and others of the tiers **102** of the fifth region **144** may include single level cells. In some embodiments, a majority (e.g., substantially all, all but one) of the tiers **102** of the fifth region **144** include triple level cells and the other of the tiers **102** (e.g., one of the tiers **102**) of the fifth region **144** may include single level cells. In some embodiments, an uppermost conductive material **106** of the fifth region **144** comprises a word line of a single level cell while the other conductive materials **106** comprise word lines of triple level cells.

The levels of the insulative material **104** and the conductive material **106** of the fifth region **144** of the second deck structure **140** may have the same thickness  $T_5$ ,  $T_6$ , respectively as the respective levels of the insulative material **104** and conductive material **106** of the third region **136**.

With continued reference to FIG. 1A, the sixth region **146** may include from 1 of the tiers **102** to 20 of the tiers **102**, such as from 1 of the tiers **102** to 4 of the tiers **102**, from 4 of the tiers **102** to 8 of the tiers **102**, from 8 of the tiers **102** to 12 of the tiers **102**, or from 12 of the tiers **102** to 20 of the tiers **102**. In some embodiments, the sixth region **146** includes 8 of the **102**. In some embodiments, the sixth region **146** includes a same number of the tiers **102** as the first region **132**.

The tiers **102** of the sixth region **146** may include conductive materials **106** that comprise one or more of select gate structures, such as select gate drain (SGD) structures or word lines of dummy memory cells. In some embodiments, at least some of the conductive materials **106** comprise dummy word lines and are not associated with a memory cell **112** storing data.

In some embodiments, about one half of the tiers **102** of the sixth region **146** include conductive materials **106** comprising select gate structures. In some such embodiments, the remaining tiers **102** comprise conductive materials **106** that form a portion of dummy tiers **102**. In some embodi-

ments, the sixth region **146** includes 4 tiers **102** comprising select gate structures and 4 dummy tiers **102**.

A thickness  $T_7$  of the insulative material **104** of each of the tiers **102** of the sixth region **146** may be within a range from about 24 nm to about 32 nm, such as from about 24 nm to about 26 nm, from about 26 nm to about 28 nm, from about 28 nm to about 30 nm, from about 30 nm to about 32 nm, or from about 32 nm to about 34 nm. In some embodiments, the thickness  $T_7$  is within a range from about 26 nm to about 30 nm. In some embodiments, the thickness  $T_7$  is about 28 nm. In some embodiments, the thickness  $T_7$  is greater than each of the thickness  $T_1$ , the thickness  $T_3$ , and the thickness  $T_5$ .

A thickness  $T_8$  of each of the conductive material **106** of each of the tiers **102** of the sixth region **146** may be within a range from about 22 nm to about 32 nm, such as from about 22 nm to about 24 nm, from about 24 nm to about 26 nm, from about 26 nm to about 28 nm, from about 28 nm to about 30 nm, or from about 30 nm to about 32 nm. In some embodiments, the thickness  $T_8$  is within a range from about 26 nm to about 28 nm. In some embodiments, the thickness  $T_8$  is about 27 nm.

Since the tiers **102** of each of the first region **132**, the second region **134**, the third region **136**, the fourth region **142**, and the fifth region **144** have different tier pitches, and since the insulative materials **104** and conductive materials **106** of the tiers **102** have different thicknesses  $T_1$ ,  $T_2$ ,  $T_3$ ,  $T_4$ ,  $T_5$ ,  $T_6$ , the memory cells **112** of such regions may have different dimensions (e.g., corresponding to the thicknesses of the conductive materials **106** of such regions) and may be spaced from each other by different distances (e.g., corresponding to the thicknesses of the insulative materials **104** of such regions). Accordingly, the first deck structure **130** may include memory cells **112** within the first region **132** spaced from each other by a distance that is greater than a distance by which the memory cells **112** of the second region **134** or the memory cells **112** of the third region **136** are spaced from each other. In addition, the memory cells **112** of the first region **132** may have a greater dimension (e.g., thickness) than the memory cells **112** of the second region **134** or the third region **136**. The memory cells **112** of the second region **134** may be spaced from each other by a distance that is greater than a distance by which the memory cells **112** of the third region **136** are spaced from each other and may have a greater dimension (e.g., thickness) than the memory cells **112** of the third region **136**. In addition, the second deck structure **140** may include memory cells **112** within the fourth region **142** with different dimensions (e.g., corresponding to the thickness of the conductive materials **106** of the fourth region **142**) and that are spaced apart from each other a greater distance (e.g., corresponding to the thickness of the insulative materials **104** of the fourth region **142**) than the memory cells **112** within the fifth region **144**.

In some embodiments, the increased tier pitch (and associated increased thickness  $T_3$  of the insulative materials **104**) of the second region **134** relative to the tier pitch of other regions (e.g., the third region **136**) may facilitate improved performance of the memory cells **112** of the second region **134** relative to the memory cells **112** of the other regions not exhibiting the increased tier pitch or associated increased thickness of the insulative materials **104** thereof. The memory cells **112** of the second region **134** may exhibit a larger read write budget (RWB) compared to memory cells **112** that are located in tiers with a smaller pitch (e.g., the memory cells **112** of the third region **136**). For example, the voltage range of the different levels of the triple level cells may be narrower for the memory cells **112** of the second

region **134** compared to the memory cells **112** of the third region **136**. Since the voltage range of the different levels of the memory cells **112** of the second region **134** is narrower, the operating voltage of such memory cells may fit within a narrower operating voltage window and the memory cells may exhibit an increased margin between individual read voltages and program verify voltages of each level of the triple level cells.

In addition, in some embodiments, the strings **110** may exhibit a taper such that portions of the strings **110** located in an upper portion of the stack structure **101** (e.g., in the fifth region **144**, the sixth region **146**) exhibit a larger dimension (e.g., diameter) than portions of the string **110** in lower portions of the stack structure **101** (e.g., portions of the string **110** in the first region **132** or the second region **134**). The smaller dimension at the lower portions (e.g., the first region **132**, the second region **134**) may result in a stronger electric field and a larger read disturb of the memory cells **112** at the lower portion (e.g., the memory cells **112** of the second region **134**) compared to memory cells of the third region **136**. Forming the memory cells **112** of the second region **134** to have a larger vertical dimensions (e.g., compared to memory cells **112** of the third region **136**) may improve the device performance of such memory cells **112**.

Further, as will be described herein, in embodiments in which the microelectronic device **100** is formed by a so-called "replacement gate" process, the microelectronic device **100** may be formed by forming a stack structure comprising tiers of the insulative materials **104** and sacrificial materials, followed by subsequent removal (e.g., exhuming, replacing) of the sacrificial materials from the stack and forming the conductive materials **106** in a volume remaining between the levels of the insulative materials **104** after removal of the sacrificial materials. In some such embodiments, formation of the insulative materials **104** having the larger thickness  $T_1$  in the first region **132** and the larger thickness  $T_2$  in the second region **134** relative to the third region **136** may reduce a likelihood of such insulative materials **104** collapsing during the replacement gate process. For example, after removal of the sacrificial materials, and due to the aspect ratio of the openings remaining between the insulative materials **104** after removal of the sacrificial materials, the insulative materials **104** may exhibit stresses, leading to bending and collapse of at least some of the remaining insulative materials **104**. Forming the insulative materials **104** of the different regions **132**, **134**, **136**, **142**, **144**, **146** to have different thicknesses  $T_1$ ,  $T_3$ ,  $T_5$ ,  $T_7$  may facilitate forming the microelectronic device **100** with a reduced risk of collapse of the insulative materials **104**. For example, forming the insulative materials **104** of the first region **132** and the second region **134** (e.g., the regions located more proximate the source material **107** and having a larger dimension (e.g., diameter)) to have larger thicknesses  $T_1$ ,  $T_3$  may facilitate forming the microelectronic device **100** with a reduce risk of collapse of such insulative materials **104**.

Although FIG. 1A has been described and illustrated as comprising different regions of tiers **102** each region including tiers **102** having a different tier pitch, the disclosure is not so limited. In other embodiments, the first deck structure **130** may include tiers **102** exhibiting a gradient in tier pitch. For example, lowermost tiers **102** may exhibit a greater tier pitch, with the tier pitch (e.g., thickness) of the tiers **102** decreasing with each tier **102** and with a distance from the source material **107**. In other words, the tiers **102** may exhibit a gradient tier pitch, with the tier pitch increasing

with a depth of the tier **102**. Similarly, the second deck structure **140** may include a gradient tier pitch. For example, lowermost tiers **102** of the second deck structure **140** may exhibit a greater tier pitch, with the tier pitch (e.g., thickness) of the tiers **102** decreasing with each tier **102** and with a distance from the interdeck structure **150**. In other words, the tiers **102** may exhibit a gradient tier pitch, with the tier pitch increasing with a depth of the tier **102**.

Accordingly, in some embodiments, a microelectronic device comprises a first set of tiers, each tier of the first set of tiers comprising alternating levels of a conductive material and an insulative material and having a first tier pitch, a second set of tiers adjacent to the first set of tiers, each tier of the second set of tiers comprising alternating levels of the conductive material and the insulative material and having a second tier pitch less than the first tier pitch, a third set of tiers adjacent to the second set of tiers, each tier of the third set of tiers comprising alternating levels of the conductive material and the insulative material and having a third tier pitch less than the second tier pitch, and a string of memory cells extending through the first set of tiers, the second set of tiers, and the third set of tiers.

Accordingly, in some embodiments, a microelectronic device comprises a stack structure comprising vertically alternating conductive structures and insulative structures arranged in tiers, each of the tiers individually comprising one of the conductive structures and one of the insulative structures. The stack structure comprises a first region comprising a first number of the tiers, each tier of the first region spaced from an adjacent tier a first distance, a second region comprising a second number of the tiers adjacent to the first region, each tier of the second region spaced from an adjacent tier a second distance less than the first distance, and a third region comprising a third number of the tiers adjacent to the second region, each tier of the third region spaced from an adjacent tier a third distance less than the second distance. The microelectronic device further comprises strings of memory cells vertically extending through the each of the first region, the second region, and the third region.

FIG. 2A through FIG. 2C are simplified cross-sectional views of a microelectronic device structure **200** illustrating a method of forming the microelectronic device **100** of FIG. 1A, in accordance with embodiments of the disclosure. With reference to FIG. 2A, the microelectronic device structure **200** may include a stack structure **201** including tiers **202** of an insulative material **204** and an other material **206**. The insulative material **204** may include one or more of the materials described above with reference to the insulative material **104**.

The other material **206** may be formed of and include a material exhibiting an etch selectivity with respect to the insulative material **204**. In some embodiments, the other material **206** comprises a nitride material (e.g., silicon nitride ( $\text{Si}_3\text{N}_4$ )) or an oxynitride material (e.g., silicon oxynitride). In some embodiments, the other material **206** comprises silicon nitride. In other embodiments, the other material **206** comprises a conductive material, such as, for example, polysilicon or tungsten.

The tiers **202** of the insulative material **204** and the other material **206** may be adjacent to (e.g., overlies) a source material **207**, which may be substantially the same as the source material **107**.

The microelectronic device structure **200** may include a first deck structure **230** adjacent to (e.g., over) the source material **207**, an interdeck structure **250** adjacent to (e.g., over) the first deck structure **230**, and a second deck struc-

ture **240** adjacent to (e.g., over) the interdeck structure **250**. The first deck structure **230** may include a first region **232**, a second region **234** adjacent to (e.g., over) the first region **232**, and a third region **236** adjacent to (e.g., over) the second region **234**. A number of tiers **202** of the first deck structure **230** and the second deck structure **240** may be substantially the same as the number of tiers **102** of the first deck structure **130** and the second deck structure **140** described above. In addition, a number of tiers **202** of each of the first region **232**, the second region **234**, and the third region **236** may be substantially the same as the number of tiers **102** of the respective ones of the first region **132**, the second region **134**, and the third region **136**.

The second deck structure **240** may include a fourth region **242** adjacent to (e.g., over) the interdeck structure **250**, a fifth region **244** adjacent to (e.g., over) the fourth region **242**, and a sixth region **246** adjacent to (e.g., over) the fifth region **244**. A number of tiers **202** of each of the fourth region **242**, the fifth region **244**, and the sixth region **246** may be substantially the same as the number of tiers **102** of the respective ones of the fourth region **142**, the fifth region **144**, and the sixth region **146**.

The tier pitch of each of the respective first region **232**, second region **234**, third region **236**, fourth region **242**, fifth region **244**, and sixth region **246** may exhibit varying tier pitches and may correspond substantially to the tier pitches of the respective ones of the first region **132**, the second region **134**, the third region **136**, the fourth region **142**, the fifth region **144**, and the sixth region **146** described above.

In some embodiments, a thickness  $T_9$  of the insulative materials **204** of the first region **232** may be about the same as the thickness  $T_1$  of the insulative materials **104**, except that the thickness  $T_9$  may be about 2 nm greater than the thicknesses  $T_1$  described above with reference to the thickness  $T_1$ . Similarly, a thickness  $T_{11}$ ,  $T_{13}$ ,  $T_{11}$ ,  $T_{13}$ ,  $T_{15}$  of the insulative materials **204** of the other regions **234**, **236**, **242**, **244**, **246** may be about the same as the thicknesses  $T_3$ ,  $T_5$ ,  $T_3$ ,  $T_5$ ,  $T_7$  of the insulative materials **104** described above, except that the thicknesses  $T_{11}$ ,  $T_{13}$ ,  $T_{11}$ ,  $T_{13}$ ,  $T_{15}$  may be about 2 nm greater than the respective thicknesses  $T_3$ ,  $T_5$ ,  $T_3$ ,  $T_5$ ,  $T_7$  described above.

In addition, a thickness  $T_{10}$  of the other materials **206** may be about the same as the thickness  $T_2$  of the conductive materials **106** described above, except that the thickness  $T_{10}$  may be about 2 nm less than the thickness  $T_2$  described above. Similarly, a thickness  $T_{12}$ ,  $T_{14}$ ,  $T_{12}$ ,  $T_{14}$ ,  $T_{16}$  of the other materials **206** of the other regions **234**, **236**, **242**, **244**, **246** may be about the same as the thicknesses  $T_4$ ,  $T_6$ ,  $T_4$ ,  $T_6$ ,  $T_8$  of the insulative materials **104** described above, except that the thicknesses  $T_{12}$ ,  $T_{14}$ ,  $T_{12}$ ,  $T_{14}$ ,  $T_{16}$  may be about 2 nm greater than the respective thicknesses  $T_4$ ,  $T_6$ ,  $T_4$ ,  $T_6$ ,  $T_8$  described above.

Accordingly, each of the insulative materials **204** and the other materials **206** may be formed (e.g., deposited) such that the tiers **202** of the different regions exhibit a different tier pitch. Referring to FIG. 2B, after forming the stack structure **201**, a staircase structure may be formed to form a stair step region **203** including steps **209** comprising edges of the tiers **202** of the insulative materials **204** and the other materials **206**. The staircase may be formed by, for example, forming a mask over the microelectronic device structure **200**, removing a portion of the mask to expose an uppermost tier **202** of the insulative material **204** and the other material **206**, removing a portion of the uppermost tier **202** of the insulative material **204** and the other material **206**, trimming a portion of the mask to expose another portion of the uppermost tier **202**, removing additional portions of the

uppermost tier **202** and portions of the insulative materials **204** and the other materials **206** exposed by removal of the portion of the mask. The process of trimming the mask and removing portions of the insulative materials **204** and the other materials **206** may be repeated a desired number of times (e.g., corresponding to the number of tiers **202**) to form the staircase structure.

After forming the staircase structure, pillar structures comprising a semiconductor material may be formed that, in combination with eventual conductive structures of the tiers **202** effectuate formation of vertically extending strings **210** of memory cells to form a memory cell region **205**. As will be described herein, the strings **210** may be formed into strings **210** of memory cells (e.g., the strings **110** (FIG. 1A) of memory cells **112** (FIG. 1A)). For example, openings may be formed in the stack structure **201** and filled with, for example, the dielectric barrier material **124**, the dielectric blocking material **122**, the memory material **120**, the tunnel dielectric material **118**, the channel material **116**, and the insulative material **114**. Of course, other types of memory cells including different materials and different structures (e.g., the memory cells **112'**, **112''**) may be formed.

After forming the strings **210** of memory cells vertically extending through the stack structure **201**, openings **280** may be formed through the stack structure **201** between some of the strings **210**. With reference to FIG. 2C, the other materials **206** may be removed through the openings **280**. For example, the other materials **206** may be exposed to a wet etchant comprising phosphoric acid to selectively remove the other materials **206** through the openings **280**. The wet etchant may include materials other than, or in addition to, phosphoric acid, for selectively removing the other materials **206** with respect to the insulative materials **204**.

With continued reference to FIG. 2C, the remaining insulative materials **204** may exhibit a cantilever shape exhibiting a relatively large aspect ratio (e.g., a ratio of the distance D from the string **210** to the opening **280** to the thickness of the insulative materials **204**). The distance D may be within a range from about, for example, 300 nm to about 350 nm, such as from about 300 nm to about 325 nm or from about 325 nm to about 350 nm. Of course, the disclosure is not so limited and the distance D may be different than those described. In some embodiments, the distance D is larger at lower portions of the openings **280**, such as in the first region **232** relative to other portions. By way of non-limiting example, in some embodiments, the distance D is greater in the first region **232** than in the second region **234**, greater in the second region **234** than in the third region **236**, greater in the third region **236** than in the fourth region **242**, etc. In some embodiments, the distance D in the third region **236** may be about 240 nm while the distance D in the first region **232** may be about 290.

Due to the large distance D relative to the thickness of the insulative materials **204**, the insulative materials **204** of conventional microelectronic device structures may be prone to failure and collapse. In addition, due to the larger distance D at the lower portions (e.g., in the first region **232**) relative to other portions, the lowermost insulative materials **204** may be more prone to collapsing. However, since the insulative materials **204** are formed to have a varying thickness, such that the lowermost insulative materials **204** have a greater thickness than other insulative materials **204**, the lowermost insulative materials **204** may be less prone to collapse compared to the insulative materials of conventional microelectronic devices.

After removing the other materials **206**, electrically conductive materials (e.g., the conductive liner material **108** and the conductive materials **106**) may be formed adjacent to the insulative materials **204** in the spaces left after removal of the other materials **206**. After forming the conductive liner materials **108** and the conductive materials **106**, the openings **280** may be filled with an insulative material to form the microelectronic device **100** of FIG. 1A.

Although FIG. 2A through FIG. 2C have been described and illustrated as forming the microelectronic device structure **200** by the replacement gate process (replacing the other materials **206**) with conductive materials (e.g., the conductive materials **106** and the conductive liner material **108**), the disclosure is not so limited. In other embodiments, the conductive materials **106** are not formed through a replacement gate process. For example, the other materials **206** may comprise an electrically conductive material that does not need to be replaced using a replacement gate process, such as, for example, polysilicon. With reference to FIG. 2A and FIG. 2B, in some such embodiments, the staircase structure may be formed to form the steps **209** and the strings **210** may be formed through the stack structure **201**. The openings **280** may not be formed through the stack structure **201**. Accordingly, a microelectronic device similar to the microelectronic device **100** of FIG. 1A may be formed, except that the microelectronic device may not include the insulative material **190** and may not include the conductive liner materials **108**.

Accordingly, in some embodiments, a method of forming a microelectronic device comprises forming a stack structure comprising vertically alternating insulative structures and other structures arranged in tiers. Forming the stack structure comprises forming a first region comprising a first number of tiers of the insulative structures and the other structures having a first tier pitch, forming, adjacent to the first region, a second region comprising a second number of tiers of the insulative structures and the other structures having a second tier pitch less than the first tier pitch, and forming, adjacent to the second region, a third region comprising a third number of tiers of the insulative structures and the other structures having a third tier pitch less than the second tier pitch. The method further comprises forming strings of memory cells extending through the stack structure, memory cells of the second region spaced farther apart from each other than memory cells of the third region.

FIG. 3 is a graph illustrating electrical properties and operating characteristics of memory cells comprising triple level cells formed according to the methods described herein. The memory cells may be similar to the memory cells **112** of the strings **110** described above with reference to FIG. 1A through FIG. 1D. In FIG. 3, the x-axis represents the voltage required to turn the memory cell on (e.g., a threshold voltage ( $V_t$ )) and the y-axis represents the percentage of cells for each level of a number of levels L0, L1, L2, L3, L4, L5, L6, L7 of the triple level cells. The levels may correspond to a state or condition of the triple level cells and may be distinguished from each other by their threshold voltage. Each level may exhibit a unique program verify (PV) threshold voltage level, PV1, PV2, PV3, PV4, PV5, PV6, and PV7. Programming of the memory cells may be performed by applying a sequence of programming pulses to the memory cells. In some embodiments, after each program pulse, a program verify pulse may be performed to determine if the threshold voltage of the particular level of the memory cell is larger than the particular PV level of the memory cell. If the threshold voltage is greater than the PV level, the memory cell may not be further programmed (e.g.,

inhibited). If the threshold voltage is less than the PV level, the memory cell may continue to receive program pulses with higher programming voltages until the threshold voltage is greater than the PV level.

In addition, each of the levels may exhibit a unique read threshold voltage, R1, R2, R3, R4, R5, R6, R7. The read threshold voltage for a particular level may be less than the program verify threshold voltage for that particular level to facilitate sufficient margin to distinguish between different levels of the memory cell. In other words, each level may have a margin between the read level threshold voltage and the  $V_t$  distribution for the level. For example, level L0 may include a margin E0 between the  $V_t$  distribution of L0 and R1. Level L1 may include a margin E1 between R1' and PV1 and margin E2 between an upper end of the  $V_t$  distribution and R2. A read window budget (RWB) may determine the operating window of the memory cells and may comprise the sum of the margins E0-E13. Forming the memory cells (e.g., the memory cells 112 of the second region 134 and the fourth region 142) to include a greater tier pitch according to embodiments described herein may facilitate forming memory cells exhibiting a narrower  $V_t$  distribution 302 for each level. The narrower  $V_t$  distribution for each level may facilitate operation of the memory cells a narrower operating range (e.g., range between R1 and PV7) of the memory cell, while maintaining the same RWB as conventional memory cells.

For example, with continued reference to FIG. 3, curve 304 represents the threshold voltage distribution of level L0 after read disturb, which may consist of a few thousand to a few hundreds of thousands of read operations of NAND cells. As illustrated in FIG. 3, the distance between L0 and R1 decreases due to the read disturb. However, since the margins E1-E13 are larger and the memory cells exhibit a narrower  $V_t$  distribution due to the structure of the memory cells formed according to embodiments described herein, the L0 memory cells may include a greater margin by increasing the value of R1 to R1' without increasing the value of PV7. In other words, since the RWB margin for TLC levels between R1 and PV7 is increased from narrower  $V_t$  of distribution of L1-L6, the value of R1 may be increased to R1' to compensate for the effects of read disturb and improve the operation of the memory cell while maintaining a sufficient margin E1-E13. Stated another way, by increasing the value of R1 to R1' for tiers 102 of the second region 134 and the fourth region 142, the margin E0' may be increased to compensate for the effects of read disturb.

Microelectronic devices including microelectronic devices (e.g., the microelectronic device 100) and microelectronic device structures (e.g., the microelectronic device structures 200) including the varying tier pitch in accordance with embodiments of the disclosure may be used in embodiments of electronic systems of the disclosure. For example, FIG. 4 is a block diagram of an electronic system 403, in accordance with embodiments of the disclosure. The electronic system 403 may comprise, for example, a computer or computer hardware component, a server or other networking hardware component, a cellular telephone, a digital camera, a personal digital assistant (PDA), portable media (e.g., music) player, a Wi-Fi or cellular-enabled tablet such as, for example, an iPad® or SURFACE® tablet, an electronic book, a navigation device, etc. The electronic system 403 includes at least one memory device 405. The memory device 405 may include, for example, an embodiment of a microelectronic device structure previously described herein (e.g., one of the microelectronic device 100 or the micro-

electronic device structure 200) previously described (with reference to FIG. 1A, FIG. 2A through FIG. 2C) including the varying tier pitch.

The electronic system 403 may further include at least one electronic signal processor device 407 (often referred to as a "microprocessor"). The electronic signal processor device 407 may, optionally, include an embodiment of a microelectronic device or a microelectronic device structure previously described herein (e.g., one or more of the microelectronic device 100 or the microelectronic device structure 200) previously described with reference to FIG. 1A and FIG. 2A through FIG. 2C). The electronic system 403 may further include one or more input devices 409 for inputting information into the electronic system 403 by a user, such as, for example, a mouse or other pointing device, a keyboard, a touchpad, a button, or a control panel. The electronic system 403 may further include one or more output devices 411 for outputting information (e.g., visual or audio output) to a user such as, for example, a monitor, a display, a printer, an audio output jack, a speaker, etc. In some embodiments, the input device 409 and the output device 411 may comprise a single touchscreen device that can be used both to input information to the electronic system 403 and to output visual information to a user. The input device 409 and the output device 411 may communicate electrically with one or more of the memory device 405 and the electronic signal processor device 407.

With reference to FIG. 5, depicted is a processor-based system 500. The processor-based system 500 may include various microelectronic devices and microelectronic device structures (e.g., microelectronic devices and microelectronic device structures including one or more of the microelectronic device 100 or the microelectronic device structure 200) manufactured in accordance with embodiments of the present disclosure. The processor-based system 500 may be any of a variety of types such as a computer, pager, cellular phone, personal organizer, control circuit, or other electronic device. The processor-based system 500 may include one or more processors 502, such as a microprocessor, to control the processing of system functions and requests in the processor-based system 500. The processor 502 and other subcomponents of the processor-based system 500 may include microelectronic devices and microelectronic device structures (e.g., microelectronic devices and microelectronic device structures including one or more of the microelectronic device 100 or the microelectronic device structure 200) manufactured in accordance with embodiments of the present disclosure.

The processor-based system 500 may include a power supply 504 in operable communication with the processor 502. For example, if the processor-based system 500 is a portable system, the power supply 504 may include one or more of a fuel cell, a power scavenging device, permanent batteries, replaceable batteries, and rechargeable batteries. The power supply 504 may also include an AC adapter; therefore, the processor-based system 500 may be plugged into a wall outlet, for example. The power supply 504 may also include a DC adapter such that the processor-based system 500 may be plugged into a vehicle cigarette lighter or a vehicle power port, for example.

Various other devices may be coupled to the processor 502 depending on the functions that the processor-based system 500 performs. For example, a user interface 506 may be coupled to the processor 502. The user interface 506 may include input devices such as buttons, switches, a keyboard, a light pen, a mouse, a digitizer and stylus, a touch screen, a voice recognition system, a microphone, or a combination

thereof. A display **508** may also be coupled to the processor **502**. The display **508** may include an LCD display, an SED display, a CRT display, a DLP display, a plasma display, an OLED display, an LED display, a three-dimensional projection, an audio display, or a combination thereof. Furthermore, an RF sub-system/baseband processor **510** may also be coupled to the processor **502**. The RF sub-system/baseband processor **510** may include an antenna that is coupled to an RF receiver and to an RF transmitter (not shown). A communication port **512**, or more than one communication port **512**, may also be coupled to the processor **502**. The communication port **512** may be adapted to be coupled to one or more peripheral devices **514**, such as a modem, a printer, a computer, a scanner, or a camera, or to a network, such as a local area network, remote area network, intranet, or the Internet, for example.

The processor **502** may control the processor-based system **500** by implementing software programs stored in the memory. The software programs may include an operating system, database software, drafting software, word processing software, media editing software, or media playing software, for example. The memory is operably coupled to the processor **502** to store and facilitate execution of various programs. For example, the processor **502** may be coupled to system memory **516**, which may include one or more of spin torque transfer magnetic random access memory (STT-MRAM), magnetic random access memory (MRAM), dynamic random access memory (DRAM), static random access memory (SRAM), racetrack memory, and other known memory types. The system memory **516** may include volatile memory, non-volatile memory, or a combination thereof. The system memory **516** is typically large so that it can store dynamically loaded applications and data. In some embodiments, the system memory **516** may include semiconductor devices, such as the microelectronic devices and microelectronic device structures (e.g., the microelectronic device **100** and the microelectronic device structure **200**) described above, or a combination thereof.

The processor **502** may also be coupled to non-volatile memory **518**, which is not to suggest that system memory **516** is necessarily volatile. The non-volatile memory **518** may include one or more of STT-MRAM, MRAM, read-only memory (ROM) such as an EPROM, resistive read-only memory (RRAM), and flash memory to be used in conjunction with the system memory **516**. The size of the non-volatile memory **518** is typically selected to be just large enough to store any necessary operating system, application programs, and fixed data. Additionally, the non-volatile memory **518** may include a high-capacity memory such as disk drive memory, such as a hybrid-drive including resistive memory or other types of non-volatile solid-state memory, for example. The non-volatile memory **518** may include microelectronic devices, such as the microelectronic devices and microelectronic device structures (e.g., the microelectronic device **100** and the microelectronic device structure **200**) described above, or a combination thereof.

Accordingly, in at least some embodiments, an electronic device comprises an input device, an output device, a processor device operably coupled to the input device and the output device, and a memory device operably coupled to the processor device and comprising at least one microelectronic device. The at least one microelectronic device comprises a stack structure comprising a deck structure comprising alternating levels of an insulative material and a conductive material, a thickness of the insulative materials within a lower portion of the deck structure greater than a thickness of the insulative materials within an upper portion

of the deck structure, and strings of memory cells extending through a stack structure, memory cells in the upper portion of the deck structure spaced apart from one another than memory cells in the lower portion of the deck structure.

While certain illustrative embodiments have been described in connection with the figures, those of ordinary skill in the art will recognize and appreciate that embodiments encompassed by the disclosure are not limited to those embodiments explicitly shown and described herein. Rather, many additions, deletions, and modifications to the embodiments described herein may be made without departing from the scope of embodiments encompassed by the disclosure, such as those hereinafter claimed, including legal equivalents. In addition, features from one disclosed embodiment may be combined with features of another disclosed embodiment while still being encompassed within the scope of the disclosure.

What is claimed is:

1. A microelectronic device, comprising:

a stack structure comprising tiers each comprising a level of conductive material and a level of insulative material vertically neighboring the level of conductive material, a vertical thickness of a lowermost one of the tiers larger than a vertical thickness of an uppermost one of the tiers, a vertical thickness of the insulative material of the lowermost one of the tiers greater than a vertical thickness of the insulative material of the uppermost one of the tiers; and strings of memory cells vertically extending through the stack structure.

2. The microelectronic device of claim 1, wherein the stack structure comprises:

a first region of the tiers comprising a first number of the tiers including the lowermost one of the tiers; and

a second region of the tiers vertically neighboring the first region of the tiers, the tiers of the second region comprising a second number of the tiers including the uppermost one of the tiers.

3. The microelectronic device of claim 2, wherein the second number of tiers is greater than the first number of tiers.

4. The microelectronic device of claim 2, wherein a thickness of the tiers of the first region decreases with an increasing distance from the lowermost one of the tiers.

5. The microelectronic device of claim 2, wherein the strings of memory cells comprise triple level memory cells within the second region.

6. The microelectronic device of claim 1, wherein a vertical thickness of the conductive material of the lowermost one of the tiers is within a range of from about two percent to about twenty percent greater than a thickness of the conductive material of the uppermost one of the tiers.

7. The microelectronic device of claim 1, wherein a vertical thickness of an additional tier vertically between the lowermost one of the tiers and the uppermost one of the tiers is less than the vertical thickness of the lowermost one of the tiers and greater than the vertical thickness of the uppermost one of the tiers.

8. A microelectronic device, comprising:

a stack structure comprising a vertically alternating sequence of insulative structures and conductive structures arranged in tiers, each of the tiers individually comprising one of the insulative structures and one of the conductive structures, the stack structure comprising:

a first region comprising a first quantity of the tiers having a first tier pitch; and

25

a second region vertically overlying the first region and comprising a second quantity of the tiers having a second tier pitch less than the first tier pitch, the first quantity of the tiers of the first region less than the second quantity of tiers of the second region.

9. The microelectronic device of claim 8, wherein a thickness of the conductive structures of the first region is greater than a thickness of the insulative structures of the first region.

10. The microelectronic device of claim 8, further comprising strings of memory cells vertically extending through the first region and the second region.

11. The microelectronic device of claim 10, wherein: the memory cells within the first region comprise single level memory cells; and the memory cells of the second region comprise triple level memory cells.

12. The microelectronic device of claim 8, wherein the second tier pitch of the second region is at least two nanometers (nm) less than the first tier pitch.

13. The microelectronic device of claim 8, further comprising:

a third region vertically overlying the second region and having a third tier pitch less than the second tier pitch; and

a fourth region vertically overlying the third region and having a fourth tier pitch substantially equal to the second tier pitch.

14. An electronic system, comprising:

an input device;

an output device;

a processor device operably coupled to the input device and the output device; and

a memory device operably coupled to the processor device and comprising at least one microelectronic device comprising:

a stack structure comprising vertically alternating levels of insulative structures and conductive structures

26

arranged in tiers, each of the tiers comprising one of the insulative structures and one of the conductive structures vertically adjacent the one of the insulative structures, each of the tiers having a vertical thickness less than or equal to a vertical thickness of each other of the tiers vertically thereunder, the stack structure comprising:

a first region of the tiers exhibiting a first substantially uniform thickness; and

a second region of the tiers vertically overlying the first region of the tiers and exhibiting a second substantially uniform vertical thickness, a vertical thickness of the insulative structures of the first region within a range of from about one percent to about ten percent greater than a vertical thickness of the insulative structures of the second region, a vertical thickness of the conductive structures of the first region within a range of from about one percent to about ten percent greater than a vertical thickness of the conductive structures of the second region; and

strings of memory cells vertically extending through the stack structure.

15. The electronic system of claim 14, wherein the stack structure comprises:

a first region of the tiers exhibiting a first substantially uniform vertical thickness; and

a second region of the tiers vertically overlying the first region of the tiers and exhibiting a second substantially uniform vertical thickness.

16. The electronic system of claim 15, further comprising a third region of the tiers vertically overlying the second region of the tiers and exhibiting a substantially uniform third vertical thickness, the third region comprising a majority of the tiers of the stack structure.

17. The electronic system of claim 14, wherein the stack structure comprises at least 128 of the tiers.
