FIELD OF THE INVENTION

The present invention relates to bicyclic heterocyclic amide derivatives that have the ability to inhibit 11β-hydroxysteroid dehydrogenase type 1 (11β-HSD-I) and which are therefore useful in the treatment of certain disorders that can be prevented or treated by inhibition of this enzyme. In addition the invention relates to the compounds, methods for their preparation, pharmaceutical compositions containing the compounds and the uses of these compounds in the treatment of certain disorder. It is expected that the compounds of the invention will find application in the treatment of conditions such as non-insulin dependent type 2 diabetes mellitus (NIDDM), insulin resistance, obesity, impaired fasting glucose, impaired glucose tolerance, lipid disorders such as dyslipidemia, hypertension and as well as other diseases and conditions.

BACKGROUND OF THE INVENTION

Glucocorticoids are stress hormones with regulatory effects on carbohydrate, protein and lipid metabolism. Cortisol (or hydrocortisone in rodent) is the most important human glucocorticoid. 11-beta hydroxyl steroid dehydrogenase or 11 beta-HSD1 (11β-HSD-I) is a member of the short chain dehydrogenase super-family of enzymes which converts functionally inert cortisone to active Cortisol locally, in a pre-receptor manner. Given that the enzyme is abundantly expressed in metabolically important tissues, such as adipose, muscle, and liver, that become resistant to insulin action in Type 2 Diabetes, inhibition of 11β-HSD-I offers the potential to restore the glucose lowering action of insulin in these tissues without impacting the central HPA. Another important 11-beta hydroxyl steroid dehydrogenase, namely Type 2 11-beta-HSD (1^β-HSD-2), which converts Cortisol into cortisone, is a unidirectional dehydrogenase mainly located in kidney and protects mineralocorticoid receptors from illicit activation by glucocorticoids.

Multiple lines of evidence indicate that 11β-HSD-I-mediated intracellular Cortisol production may have a pathogenic role in Obesity, Type 2 Diabetes and its co-morbidities.

In humans, treatment with non-specific inhibitor carbenoxolone improves insulin sensitivity in lean healthy volunteers and people with type 2 diabetes (Walker B R et al (1995)). Likewise, 11β-HSD-I activity was decreased in liver and increased in the adipose tissue of obese individuals. Similarly 11β-HSD-I mRNA was found to be increased in both visceral and subcutaneous adipose tissue of obese patients (Desbriere R et al (2006)) and was positively related to BMI and central obesity in Pima Indians, Caucasians and Chinese
youth (Lindsay RS et al (2003), Lee ZS et al (1999)). Adipose tissue I\(\iota\)\(\beta\)-HSD-I and Hexose-6-Phosphate Dehydrogenase gene expressions have also been shown to increase in patients with type 2 diabetes mellitus (Uckaya G et al (2008)). In human skeletal muscle 11\(\beta\)-HSD-1 expression was found to be positively associated with insulin resistance (Whorwood CB et al (2002)). Increased I\(\iota\)\(\beta\)-HSD-I expression was also seen in diabetic myotubes (Abdallah BM et al (2005)).

Various studies have been conducted in rodent models to substantiate the role of 11\(\beta\)-HSD-1 in diabetes and obesity. For example, over-expression of I\(\iota\)\(\beta\)-HSD-I specifically in adipose tissue causes development of metabolic syndrome (glucose intolerance, obesity, dyslipidemia and hypertension) in mice (Masuzaki H et al (2001)). Conversely, when 11\(\beta\)-HSD-1 gene was knocked out, the resulting mice showed resistance to diet induced obesity and improvement of the accompanying dysregulation of glucose and lipid metabolism (Kotelevtsev Y et al (1997), Morton NM et al (2001), Morton NM et al (2004)). In addition, treatment of diabetic mouse models with specific inhibitors of 11\(\beta\)-HSD-1 caused a decrease in glucose output from the liver and overall increase in insulin sensitivity (Alberts P et al (2003)).

The results of the preclinical and early clinical studies suggest that the treatment with a selective and potent inhibitor of I\(\iota\)\(\beta\)-HSD-I will be an efficacious therapy for type 2 diabetes, obesity and metabolic syndrome.

The role of I\(\iota\)\(\beta\)-HSD-I as an important regulator of liver glucocorticoid level and thus of hepatic glucose production is well substantiated. Hepatic insulin sensitivity was improved in healthy human volunteers treated with the non-specific I\(\iota\)\(\beta\)-HSD-I inhibitor carbenoxolone (Walker BR (1995)). Many in vitro and in vivo (animal model) studies showed that the mRNA levels and activities of two key enzymes (PEPCK and G6PC) in gluconeogenesis and glycogenolysis were reduced by reducing I\(\iota\)\(\beta\)-HSD-I activity. Data from these models also confirm that inhibition of 11\(\beta\)-HSD-I will not cause hypoglycemia, as predicted since the basal levels of PEPCK and G6Pase are regulated independently of glucocorticoids (Kotelevtsev Y (1997)).

In the pancreas Cortisol is shown to inhibit glucose induced insulin secretion as well as increase stress induced beta cell apoptosis. Inhibition of I\(\iota\)\(\beta\)-HSD-I by carbenoxolone in isolated murine pancreatic beta-cells improves glucose-stimulated insulin secretion (Davani B et al (2000)). Recently, it was shown that I\(\iota\)\(\beta\)-HSD-I within alpha cells regulates glucagon secretion and in addition may act in a paracrine manner to limit insulin secretion from beta
Levels of 11β-HSD-I in islets from ob/ob mice were shown to be positively regulated by glucocorticoids and were lowered by a selective 11β-HSD-I inhibitor and a glucocorticoid receptor antagonist. Increased levels of 11β-HSD-I were associated with impaired GSIS (Ortsater H et al (2005)). In Zucker diabetic rats, troglitazone treatment improved metabolic abnormalities with a 40% decline in expression of 11β-HSD-I in the islets (Duplomb L et al (2004)). Cortisol inhibition may lead to an increase in the insulin gene transcription and a normalization of first phase insulin secretion (Shinozuka Y et al (2001)).

In human skeletal muscle 11β-HSD-I expression is positively associated insulin resistance and increased expression of 11β-HSD-I was also reported in type 2 diabetic myotubes (Abdallah BM et al (2005)). Recently the contribution of Cortisol in muscle pathology is being considered for modulating its action. Very recently it has been demonstrated that targeted reduction or pharmacological inhibition of 11β-HSD-I in primary human skeletal muscle prevents the effect of cortisone on glucose metabolism and palmitate oxidation (Salehzadeh F et al (2009)). Over activity of Cortisol in muscle leads to muscle atrophy, fibre type switch and poor utilization of glucose due to insulin resistance. Cortisol might have a direct role in reducing muscle glucose uptake.

Obesity is an important factor in Metabolic syndrome as well as in the majority (>80%) of type 2 diabetics, and omental (visceral) fat appears to be of central importance. 11β-HSD-I activity is increased in the both visceral and subcutaneous adipose tissue of obese individual (Lindsay RS et al (2003)). Cortisol activity in adipose is known to increase the adipogenic program. Inhibition of 11β-HSD-I activity in pre-adipocytes has been shown to decrease the rate of differentiation into adipocytes (Bader T et al (2002)). This is predicted to result in diminished expansion (possibly reduction) of the omental fat depot, i.e., reduced central obesity (Bujalska IJ et al (1997) and (2006)). Intra-adipose Cortisol levels have been associated with adipose hypertrophy, independent of obesity (Michailidou Z et al (2006)).

Cortisol in coordination with adrenergic signalling is also known to increase lipolysis which leads to increase in plasma free fatty acid concentrations which, in turn, is the primary cause of many deleterious effects of obesity (Tomlinson JW et al (2007)).

Adrenalectomy attenuates the effect of fasting to increase both food intake and hypothalamic neuropeptide Y expression. This supports the role of glucocorticoids in promoting food intake and suggests that inhibition of 11β-HSD-I in the brain might increase satiety and therefore reduce food intake (Woods SC (1998)). Inhibition of 11β-HSD-I by a
small molecule inhibitor also decreased food intake and weight gain in diet induced obese mice (Wang SJY et al (2006)).

The effects discussed above therefore suggest that an effective I1 β-HSD-1 inhibitor would have activity as an anti-obesity agent.

Cortisol in excess can also trigger triglyceride formation and VLDL secretion in liver, which can contribute to hyperlipidemia and associated dyslipidemia. It has been shown that 11P-HSD-1/- transgenic mice have markedly lower plasma triglyceride levels and increased HDL cholesterol levels indicating a potential atheroprotective phenotype (Morton NM et al (2001)). In a diet-induced obese mouse model, a non-selective inhibitor of I1 β-HSD-1 reduced plasma free fatty acid as well as triacylglycerol (Wang SJ et al (2006)). Over-expression of I1 β-HSD-1 in liver increased liver triglyceride and serum free fatty acids with the up regulation of hepatic lipogenic genes (Paterson JM et al (2004). It has been illustrated that inhibition of 11β-HSD-1 improves triglyceridemia by reducing hepatic VLDL-TG secretion, with a shift in the pattern of TG-derived fatty acid uptake toward oxidative tissues, in which lipid accumulation is prevented by increased lipid oxidation (Berthiaume M et al (2007)).

Atherosclerotic mouse model (APOE -/-) which are susceptible to atheroma when fed high fat diet, are protected against development of atherosclerosis when treated with 11β-HSD-1 inhibitors (Hermanowski-Vostaka A et al, (2005)).

Inhibition of 11p-HSD-1 in mature adipocytes is expected to attenuate secretion of the plasminogen activator inhibitor 1 (PAI-1)– an independent cardiovascular risk factor (Halleux CM et al (1999)). Furthermore, there is a clear correlation between glucocorticoid activity and cardiovascular risk factor suggesting that a reduction of the glucocorticoid effects would be beneficial (Walker BR et al (1998), Fraser R et al (1999)).

The association between hypertension and insulin resistance might be explained by increased activity of Cortisol. Recent data show that the intensity of dermal vasoconstriction after topical application of glucocorticoids is increased in patients with essential hypertension (Walker BR et al (1998)). Glucocorticoid was shown to increase the expression of angiotensin receptor in vascular cell and thus potentiating the renin-angiotensin pathway (Ullian ME et al (1996)), (Sato A et al (1994)). Role of Cortisol in NO signalling and hence vasoconstriction has been proved recently (Liu Y et al (2009)). These findings render 11β-HSD-1 a potential target for controlling hypertension and improving blood-flow in target tissues.
In the past decade, concern on glucocorticoid-induced osteoporosis has increased with the widespread use of exogenous glucocorticoids (GC). GC-induced osteoporosis is the most common and serious side-effect for patients receiving GC. Loss of bone mineral density (BMD) is greatest in the first few months of GC use. Mature bone-forming cells (osteoblasts) are considered to be the principal site of action of GC in the skeleton. The whole differentiation of mesenchymal stem cell toward the osteoblast lineage has been proven to be sensitive to GC as well as collagen synthesis (Kim CH et al (1999)). The effects of GC on this process are different according to the stage of differentiation of bone cell precursors. The presence of intact GC signalling is crucial for normal bone development and physiology, as opposed to the detrimental effect of high dose exposure (Pierotti S et al (2008), Cooper MS et al (2000)). Other data suggest a role of 1\(^1\)\(\beta\)-HSD-I in providing sufficiently high levels of active glucocorticoid in osteoclasts, and thus in augmenting bone resorption (Cooper M S et al (2000)). The negative effect on bone nodule formation could be blocked by the non-specific inhibitor carbenoxolone suggesting an important role of 1\(\pi\)-HSD-1 in the glucocorticoid effect (Bellows C G et al (1998)).

Stress and glucocorticoids influence cognitive function (de Quervain DJ et al (1998)). The enzyme 1\(\Pi\)\(\beta\)-HSD-I controls the level of glucocorticoid action in the brain also known to contributes to neurotoxicity (Rajan V et al (1996)). It has been also suggested that inhibiting 1\(\Pi\)\(\beta\)-HSD-I in the brain may result in reduced anxiety (Tranche F et al (1999)). Thus, taken together, the hypothesis is that inhibition of 1\(\Pi\)\(\beta\)-HSD-I in the human brain would prevent reactivation of cortisone into Cortisol and protect against deleterious glucocorticoid-mediated effects on neuronal survival and other aspects of neuronal function, including cognitive impairment, depression, and increased appetite.

Recent data suggest that the levels of the glucocorticoid target receptors and the 11\(\beta\)-HSD-I enzymes determine the susceptibility to glaucoma (Stokes, J. et al. (2000)). Ingestion of carbenoxolone, a non-specific inhibitor of 11\(\beta\)-HSD-I, was shown to reduce the intraocular pressure by 20% in normal subjects. There are evidences that 11\(\beta\)-HSD-I isozyme may modulate steroid-regulated sodium transport across the NPE, thereby influencing intraocular pressure (IOP). 1\(\pi\)-HSD-1 is suggested to have a role in aqueous production, rather than drainage, but it is presently unknown if this is by interfering with activation of the glucocorticoid or the mineralocorticoid receptor, or both (Rauz S et al (2001; 2003)).

The multitude of glucocorticoid action is exemplified in patients with prolonged increase in plasma glucocorticoids, so called "Cushing's syndrome". These patients have
prolonged increase in plasma glucocorticoids and exhibit impaired glucose tolerance, type 2 diabetes, central obesity, and osteoporosis. These patients also have impaired wound healing and brittle skin. Administration of glucocorticoid receptor agonist (RU38486) in Cushing’s syndrome patients reverses the features of metabolic syndrome (Neiman LK et al (1985)).

Glucocorticoids have been shown to increase risk of infection and delay healing of open complications wounds. Patients treated with glucocorticoids have 2-5-fold increased risk of lesions when undergoing surgery. Glucocorticoids influence wound healing by interfering with production or action of cytokines and growth factors like IGF, TGF-beta, EGF, KGF and PDGF (Beer HD et al (2000)). TGF-beta reverses the glucocorticoid-induced wound-healing deficit in rats by PDGF regulation in macrophages (Pierce GF et al (1989)). It has also been shown that glucocorticoids decrease collagen synthesis in rat and mouse skin in vivo and in rat and human fibroblasts (Oishi Y et al, 2002).

Glucocorticoids have also been implicated in conditions as diverse as polycystic Ovaries Syndrome, infertility, memory dysfunction, sleep disorders, myopathy (Endocrinology. 2011 Jan; 152(1):93-102. Epub 2010 Nov 24.PMID: 21106871) and muscular dystrophy. As such the ability to target enzymes that have an impact on glucocorticoid levels is expected to provide promise for the treatment of these conditions:

Based on patent literature and company press releases, there are many compound tested for 11β-HSD-I inhibition in the different stages of drug discovery pipeline.

Incyte Corporation's INCB13739 has proceeded furthest to phase lib stage of clinical trial. The results of phase IIa trial for type 2 diabetes (28-days, placebo-controlled, two-step hyperinsulinemic clamp studies) showed that it was safe and well tolerated without any serious side effects and hypoglycemia.

Though this molecule significantly improved hepatic insulin sensitivity there was no appreciable improvement in plasma glucose levels. The molecule appeared to be having positive effects on risk factors for cardiovascular disease including reduction of LDL, total cholesterol and triglycerides as well as more modest increases in HDL. INCB13739 is currently being studied in a dose ranging phase II b trials in T2D patients whose glucose levels are not controlled by metformin monotherapy.
In the pre-clinical stage, Incyte's lead inhibitor 1NCB13739 was tested in rhesus monkey and was shown to inhibit adipose 11P-HSD-1 (INCB013739, a selective inhibitor of 11β-Hydroxysteroid Dehydrogenase Type 1 (11βHSD1) improves insulin sensitivity and lowers plasma cholesterol over 28 days in patients with type 2 diabetes mellitus.

The evidence therefore strongly suggests that compounds that are inhibitors of 11β-Hydroxysteroid Dehydrogenase would be useful in the treatment of a number of clinical conditions associated with the expression of this enzyme. In addition it would be desirable if the inhibitors were selective inhibitors so as not to interfere with the functioning of closely related enzymes such as 11β-HSD-2 which is known to provide a protective effect in the body.

DETAILED DESCRIPTION OF THE INVENTION

In this specification a number of terms are used which are well known to a skilled addressee. Nevertheless for the purposes of clarity a number of terms will be defined.

As used herein, the term "unsubstituted" means that there is no substituent or that the only substituents are hydrogen.

The term "optionally substituted" as used throughout the specification denotes that the group may or may not be further substituted or fused (so as to form a condensed polycyclic system), with one or more non-hydrogen substituent groups. together with the atoms to which they are attached form a heterocyclic ring system with 3 to 12 ring atoms.

In the definitions of a number of substituents below it is stated that "the group may be a terminal group or a bridging group". This is intended to signify that the use of the term is intended to encompass the situation where the group is a linker between two other portions of the molecule as well as where it is a terminal moiety. Using the term alkyl as an example, some publications would use the term "alylene" for a bridging group and hence in these other publications there is a distinction between the terms "alkyl" (terminal group) and "alylene" (bridging group). In the present application no such distinction is made and most groups may be either a bridging group or a terminal group.

It is understood that included in the family of compounds of Formula (I) are isomeric forms including diastereoisomers, enantiomers, tautomers, and geometrical isomers in "E" or "Z" configurational isomer or a mixture of E and Z isomers. It is also understood that some isomeric forms such as diastereomers, enantiomers, and geometrical isomers can be separated by physical and/or chemical methods and by those skilled in the art. For those compounds where there is the possibility of geometric isomerism the applicant has drawn the isomer that the compound is thought to be although it will be appreciated that the other isomer may be the correct structural assignment.
Some of the compounds of the disclosed embodiments may exist as single stereoisomers, racemates, and/or mixtures of enantiomers and/or diastereomers. All such single stereoisomers, racemates and mixtures thereof, are intended to be within the scope of the subject matter described and claimed.

Additionally, Formula (I) is intended to cover, where applicable, solvated as well as unsolvated forms of the compounds. Thus, each formula includes compounds having the indicated structure, including the hydrated as well as the non-hydrated forms.

The term "pharmaceutically acceptable salts" refers to salts that retain the desired biological activity of the above-identified compounds, and include pharmaceutically acceptable acid addition salts and base addition salts. Suitable pharmaceutically acceptable acid addition salts of compounds of Formula (I) may be prepared from an inorganic acid or from an organic acid. Examples of such inorganic acids are hydrochloric, sulfuric, and phosphoric acid. Appropriate organic acids may be selected from aliphatic, cycloaliphatic, aromatic, heterocyclic carboxylic and sulfonic classes of organic acids, examples of which are formic, acetic, propanoic, succinic, glycolic, gluconic, lactic, malic, tartaric, citric, fumaric, maleic, alkyl sulfonic, aroylsulfonic. Additional information on pharmaceutically acceptable salts can be found in Remington's Pharmaceutical Sciences, 19th Edition, Mack Publishing Co., Easton, PA 1995. In the case of agents that are solids, it is understood by those skilled in the art that the inventive compounds, agents and salts may exist in different crystalline or polymorphic forms, all of which are intended to be within the scope of the present invention and specified formulae.

"Prodrug" means a compound that undergoes conversion to a compound of formula (I) within a biological system, usually by metabolic means (e.g. by hydrolysis, reduction or oxidation). For example an ester prodrug of a compound of formula (I) containing a hydroxyl group may be convertible by hydrolysis in vivo to the parent molecule. Suitable esters of compounds of formula (I) containing a hydroxyl group, are for example acetates, citrates, lactates, tartrates, malonates, oxalates, salicylates, propionates, succinates, fumarates, maleates, methylene-bis^*-hydroxynaphthoates, gestisates, isethionates, di-p-toluoyltartrates, methanesulphonates, ethanesulphonates, benzenesulphonates, p-toluenesulphonates, cyclohexylsulphamates and quinates. As another example an ester prodrug of a compound of formula (I) containing a carboxy group may be convertible by hydrolysis in vivo to the parent molecule. (Examples of ester prodrugs are those described by F.J. Leinweber, Drug Metab. Res., 18:379, 1987). Similarly, an acyl prodrug of a compound of formula (I)
containing an amino group may be convertible by hydrolysis \textit{in vivo} to the parent molecule. (Many examples of prodrugs for these and other functional groups, including amines, are described in Prodrugs: Challenges and Rewards (Parts 1 and 2); Ed V. Stella, R. Borchardt, M. Hageman, R. Oliyai, H. Maag and J Tilley; Springer, 2007).

The term "therapeutically effective amount" or "effective amount" is an amount sufficient to effect beneficial or desired clinical results. An effective amount can be administered in one or more administrations. An effective amount is typically sufficient to palliate, ameliorate, stabilize, reverse, slow or delay the progression of the disease state.

Specific compounds of the invention include the following:
The compounds have the ability to inhibit 11β-HSD1. The ability to inhibit 11β-HSD1 may be a result of the compounds acting directly and solely on the 11β-HSD1 to modulate/potentiate biological activity. However, it is understood that the compounds may also act at least partially on other factors associated with 11β-HSD1 activity.

The inhibition of 11β-HSD1 may be carried out in any of a number of ways known in the art. For example if inhibition of 11β-HSD1 in vitro is desired an appropriate amount of the compound may be added to a solution containing the 11β-HSD1. In circumstances where it is desired to inhibit 11β-HSD1 in a mammal, the inhibition of the 11β-HSD1 typically involves administering the compound to a mammal containing the 11β-HSD1.

Accordingly the compounds may find a multiple number of applications in which their ability to inhibit 11β-HSD1 enzyme of the type mentioned above can be utilised.

Accordingly compounds of the invention would be expected to have useful therapeutic properties especially in relation to diabetes, hyperglycemia, low glucose tolerance, hyperinsulinemia, hyperlipidemia, hypertriglyceridemia, hypercholesterolemia, dyslipidemia, obesity, abdominal obesity, glaucoma, hypertension, atherosclerosis and its sequelae,
retinopathy and other ocular disorders, nephropathy, neuropathy, myopathy, osteoporosis, osteoarthritis, dementia, depression, neurodegenerative disease, psychiatric disorders, Polycystic ovaries syndrome, infertility, Cushing's Disease, Cushing's syndrome, virus diseases, and inflammatory diseases.

Administration of compounds within Formula (I) to humans can be by any of the accepted modes for enteral administration such as oral or rectal, or by parenteral administration such as subcutaneous, intramuscular, intravenous and intradermal routes. Injection can be bolus or via constant or intermittent infusion. The active compound is typically included in a pharmaceutically acceptable carrier or diluent and in an amount sufficient to deliver to the patient a therapeutically effective dose. In various embodiments the activator compound may be selectively toxic or more toxic to rapidly proliferating cells, e.g. cancerous tumours, than to normal cells.

In using the compounds of the invention they can be administered in any form or mode which makes the compound bioavailable. One skilled in the art of preparing formulations can readily select the proper form and mode of administration depending upon the particular characteristics of the compound selected, the condition to be treated, the stage of the condition to be treated and other relevant circumstances. We refer the reader to Remingtons Pharmaceutical Sciences, 19th edition, Mack Publishing Co. (1995) for further information.

The compounds of the present invention can be administered alone or in the form of a pharmaceutical composition in combination with a pharmaceutically acceptable carrier, diluent or excipient. The compounds of the invention, while effective themselves, are typically formulated and administered in the form of their pharmaceutically acceptable salts as these forms are typically more stable, more easily crystallised and have increased solubility.

The compounds are, however, typically used in the form of pharmaceutical compositions which are formulated depending on the desired mode of administration. As such in some embodiments the present invention provides a pharmaceutical composition including a compound of Formula (I) and a pharmaceutically acceptable carrier, diluent or excipient. The compositions are prepared in manners well known in the art.

The invention in other embodiments provides a pharmaceutical pack or kit comprising one or more containers filled with one or more of the ingredients of the pharmaceutical compositions of the invention. In such a pack or kit can be found a container having a unit
dosage of the agent(s). The kits can include a composition comprising an effective agent either as concentrates (including lyophilized compositions), which can be diluted further prior to use or they can be provided at the concentration of use, where the vials may include one or more dosages. Conveniently, in the kits, single dosages can be provided in sterile vials so that the physician can employ the vials directly, where the vials will have the desired amount and concentration of agent(s). Associated with such container(s) can be various written materials such as instructions for use, or a notice in the form prescribed by a governmental agency regulating the manufacture, use or sale of pharmaceuticals or biological products, which notice reflects approval by the agency of manufacture, use or sale for human administration.

The compounds of the invention may be used or administered in combination with one or more additional drug(s) for the treatment of the disorder/diseases mentioned. The components can be administered in the same formulation or in separate formulations. If administered in separate formulations the compounds of the invention may be administered sequentially or simultaneously with the other drug(s).

In addition to being able to be administered in combination with one or more additional drugs, the compounds of the invention may be used in a combination therapy. When this is done the compounds are typically administered in combination with each other. Thus one or more of the compounds of the invention may be administered either simultaneously (as a combined preparation) or sequentially in order to achieve a desired effect. This is especially desirable where the therapeutic profile of each compound is different such that the combined effect of the two drugs provides an improved therapeutic result.

Pharmaceutical compositions of this invention for parenteral injection comprise pharmaceutically acceptable sterile aqueous or nonaqueous solutions, dispersions, suspensions or emulsions as well as sterile powders for reconstitution into sterile injectable solutions or dispersions just prior to use. Examples of suitable aqueous and nonaqueous carriers, diluents, solvents or vehicles include water, ethanol, polyols (such as glycerol, propylene glycol, polyethylene glycol, and the like), and suitable mixtures thereof, vegetable oils (such as olive oil), and injectable organic esters such as ethyl oleate. Proper fluidity can be maintained, for example, by the use of coating materials such as lecithin, by the maintenance of the required particle size in the case of dispersions, and by the use of surfactants.
These compositions may also contain adjuvants such as preservative, wetting agents, emulsifying agents, and dispersing agents. Prevention of the action of micro-organisms may be ensured by the inclusion of various antibacterial and antifungal agents, for example, paraben, chlorobutanol, phenol sorbic acid, and the like. It may also be desirable to include isotonic agents such as sugars, sodium chloride, and the like. Prolonged absorption of the injectable pharmaceutical form may be brought about by the inclusion of agents that delay absorption such as aluminium monostearate and gelatin.

If desired, and for more effective distribution, the compounds can be incorporated into slow release or targeted delivery systems such as polymer matrices, liposomes, and microspheres.

The injectable formulations can be sterilized, for example, by filtration through a bacterial-retaining filter, or by incorporating sterilizing agents in the form of sterile solid compositions that can be dissolved or dispersed in sterile water or other sterile injectable medium just prior to use.

Solid dosage forms for oral administration include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound is mixed with at least one inert, pharmaceutically acceptable excipient or carrier such as sodium citrate or dicalcium phosphate and/or a) fillers or extenders such as starches, lactose, sucrose, glucose, mannitol, and silicic acid, b) binders such as, for example, carboxymethylcellulose, alginates, gelatin, polyvinylpyrrolidone, sucrose, and acacia, c) humectants such as glycerol, d) disintegrating agents such as agar-agar, calcium carbonate, potato or tapioca starch, alginic acid, certain silicates, and sodium carbonate, e) solution retarding agents such as paraffin, f) absorption accelerators such as quaternary ammonium compounds, g) wetting agents such as, for example, cetyl alcohol and glycerol monostearate, h) absorbents such as kaolin and bentonite clay, and i) lubricants such as talc, calcium stearate, magnesium stearate, solid polyethylene glycols, sodium lauryl sulfate, and mixtures thereof. In the case of capsules, tablets and pills, the dosage form may also comprise buffering agents.

Solid compositions of a similar type may also be employed as fillers in soft and hard-filled gelatin capsules using such excipients as lactose or milk sugar as well as high molecular weight polyethylene glycols and the like.

The solid dosage forms of tablets, dragees, capsules, pills, and granules can be prepared with coatings and shells such as enteric coatings and other coatings well known in
the pharmaceutical formulating art. They may optionally contain opacifying agents and can also be of a composition that they release the active ingredient(s) only, or preferentially, in a certain part of the intestinal tract, optionally, in a delayed manner. Examples of embedding compositions which can be used include polymeric substances and waxes.

5

The active compounds can also be in microencapsulated form, if appropriate, with one or more of the above-mentioned excipients.

Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, solutions, suspensions, syrups and elixirs. In addition to the active compounds, the liquid dosage forms may contain inert diluents commonly used in the art such as, for example, water or other solvents, solubilizing agents and emulsifiers such as ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propylene glycol, 1,3-butylene glycol, dimethyl formamide, oils (in particular, cottonseed, groundnut, corn, germ, olive, castor, and sesame oils), glycerol, tetrahydrofurfuryl alcohol, polyethylene glycols and fatty acid esters of sorbitan, and mixtures thereof.

Besides inert diluents, the oral compositions can also include adjuvants such as wetting agents, emulsifying and suspending agents, sweetening, flavoring, and perfuming agents.

Suspensions, in addition to the active compounds, may contain suspending agents as, for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol and sorbitan esters, microcrystalline cellulose, aluminium metahydroxide, bentonite, agar-agar, and tragacanth, and mixtures thereof.

Compositions for rectal or vaginal administration are preferably suppositories which can be prepared by mixing the compounds of this invention with suitable non-irritating excipients or carriers such as cocoa butter, polyethylene glycol or a suppository wax which are solid at room temperature but liquid at body temperature and therefore melt in the rectum or vaginal cavity and release the active compound.

Dosage forms for topical administration of a compound of this invention include powders, patches, sprays, ointments and inhalants. The active compound is mixed under sterile conditions with a pharmaceutically acceptable carrier and any needed preservatives, buffers, or propellants which may be required.
The amount of compound administered will preferably treat and reduce or alleviate the condition. A therapeutically effective amount can be readily determined by an attending diagnostician by the use of conventional techniques and by observing results obtained under analogous circumstances. In determining the therapeutically effective amount a number of factors are to be considered including but not limited to, the species of animal, its size, age and general health, the specific condition involved, the severity of the condition, the response of the patient to treatment, the particular compound administered, the mode of administration, the bioavailability of the preparation administered, the dose regime selected, the use of other medications and other relevant circumstances.

A preferred dosage will be a range from about 0.01 to 300 mg per kilogram of body weight per day. A more preferred dosage will be in the range from 0.1 to 100 mg per kilogram of body weight per day, more preferably from 0.2 to 80 mg per kilogram of body weight per day, even more preferably 0.2 to 50 mg per kilogram of body weight per day. A suitable dose can be administered in multiple sub-doses per day.

The compound of the invention may also be administered in combination with (or simultaneously or sequentially with) an adjuvant to increase compound performance. Suitable adjuvants may include (a) dipeptidyl peptidase-IV (DP-IV) inhibitors; (b) insulin sensitizing agents; (iv) biguanides; (c) insulin and insulin mimetics; (d) sulfonylureas and other insulin secretagogues; (e) alpha-glucosidase inhibitors; and (f) GLP-1, GLP-1 analogs, and GLP-1 receptor agonists. The adjuvants may be part of the same composition, or the adjuvants may be administered separately (either simultaneously or sequentially). The order of the administration of the composition and the adjuvant will generally be known to the medical practitioner involved and may be varied.

¹H NMR spectra were recorded on a Bruker AV 300. Chemical shifts are expressed in parts per million (ppm, δ units). Coupling constants are in units of hertz (Hz). Splitting patterns describe apparent multiplicities and are designated as s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), or br (broad).

Mass spectra were obtained on single quadruple 6120 LCMS from Agilent technologies, using either atmospheric chemical ionization (APCI) or Electrospray ionization (ESI) or in the combination of these two sources.

All samples were run on SHIMADZU system with an LC-20 AD pump, SPD-M20A diode array detector, SIL-20A auto sampler.
SYNTHETIC SCHEME 1

The resulting solution was stirred at room temperature overnight. After completion of the reaction (reaction monitored by TLC), the solvent was removed under reduced pressure, and the resulting crude compound was purified by column chromatography on silica gel (230-400 mesh) using Petroleum ether (60-80) and ethyl acetate as eluent. The product (intermediate 1) was obtained as a brown liquid (2.51 g). LC-MS (M-H)^+ = 286.

A 100 mL RB flask fitted with magnetic stirrer was charged with intermediate-1 (2.5g, 8.7 mmol) in 50mL of pyridine and 8 ml of ethanol. To this mixture copper powder (0.4g, 5 mol%) was added. Then the resulting reaction mass was refluxed at 110° for 3 hours. After completion of the reaction (reaction monitored by TLC), solvent was removed from the reaction mass and the reaction mass was diluted with 100mL of ethyl acetate, washed with 50mL 1.5N HCl (2X25mL) and brine solution. Then the organic layer was dried over anhydrous MgSO₄. The solvent was removed under reduced pressure, and the resulting crude compound was purified by column chromatography on silica gel (230-400 mesh) using.
Petroleum ether (60-80) and ethyl acetate as eluent. The product (intermediate 2) was obtained as a brown liquid. (0.380g). LC-MS (M+H)⁺ = 232.

Then the resulting reaction mass was refluxed at 70°C for 3 hours. After completion of the reaction (reaction monitored by TLC), solvent was removed from the reaction mass and the reaction mass was diluted with 20mL of water. The resulting aqueous layer was then washed with 20 mL of diethyl ether. The aqueous layer was acidified by 1NHCl to pH 5.5 and product was extracted with ethyl acetate and the solvent was removed under reduced pressure. The product (intermediate 3) was obtained as a brown liquid (0.115g). The product obtained above was directly taken for next step without any purification.

Intermediate-94 was synthesized by following the procedure used to make Intermediate-2 (Scheme-1).

Synthesis of ethyl 3-(4-cyclopropyl-1H-indol-3-yl)butanoate (intermediate-95):
A 250mL RB flask fitted with magnetic stirrer was charged with Intermediate-94 (15.95g, 51.47mmol), cyclopropylboronic acid (8.8g, 102.9 mmol), cesium carbonate (33.45g, 102.9mmol), in a mixture of dioxane and water (100 ml : 20 ML). Then purged with N₂ gas and added PdCl₂(dppf) (4.2g, 5.1 mmol). Resulting solution was stirred at 100 °C for 13 h. After completion of the reaction (reaction monitored by TLC), reaction solution was filtered through celite. Filtrate diluted with water and extracted with EtOAc and concentrated to give crude material, which is purified by silica gel column chromatography eluting with Petroleum ether (60-80) and ethyl acetate as eluent. The product (intermediate-95) was obtained as a brown liquid (12.5g).

Synthesis of Intermediate-110:

To a stirred solution of Starting Material-34 (1.0 g, 5.26 mmol) in water (5 mL) sodium bicarbonate (1.06 g, 12.6 mmol) was added at room temperature and stirred for 30 min. To this n-hexane (5 mL) followed by selectfluor (2.23 g, 6.31 mmol) was added at 10 °C and stirred for 2 hours at same temperature. After reaction hexane layer was separated and dried over anhydrous MgSO₄ to give crude intermediate-1 10 hexane solution, which was taken for next step without any purification.

Synthesis of Intermediate-11:

To a stirred solution of Intermediate-110 hexanes solution (0.863 g, 5.26 mmol) in ether (5 mL) was added 2.5 M n-BuLi (2.52 mL, 6.31 mmol) at -78°C and stirred for 20 minutes. To this tributyltin chloride (1.56 mL, 5.78 mmol) was added and stirred for 10 min at -78 °C, then
rt for 12 h. After reaction quenched with aqueous 1N NaOH solution and extracted with EtOAc and concentrated to give crude material Intermediate-1 11 (0.95 g) as brown liquid.

Synthetic Scheme-69
Synthesis of Intermediate 129: To a stirred solution of Starting Material-35 (40 g, 206 mmol) in ether (400 mL), oxalyl chloride (23.2 mL, 268 mmol) was added at 0 °C, and stirred at room temperature for 5 hours. The reaction mixture was then filtered and washed with ether to get solid material (42 g), which was treated with MeOH (28 mL) in ether (200 mL) at 0 °C to room temperature for 5 hours. After completion of the reaction, the reaction mixture was diluted with hexanes, resulted precipitate was filtered and dried to get Intermediate-1 29 (35 g) as yellow solid.

Synthesis of Intermediate-130: To a stirred solution of Intermediate-1 29 (35 g, 129 mmol) in MeOH (350 mL), tosyl hydrazine (23.1 g, 129 mmol) was added and refluxed for 4 hours. After completion of the reaction, the reaction mixture was concentrated to give crude mixture, which was diluted with H₂O, extracted with DCM and concentrated to give Intermediate-1 30 (35 g) as pale yellow solid.

Synthesis of Intermediate-131: To a stirred solution of Intermediate-1 31 (14 g, 31 mmol) in THF (140mL), NaBH₄ (1.8 g, 46 mmol) was added at 0 °C and continued to stir at room temperature for 6 hours. After completion of the reaction, the reaction mixture was quenched with H₂O, extracted with DCM and concentrated. The resulted crude product was purified by using silica gel column chromatography elutive with mixture of hexanes, EtOAc to give Intermediate-1 31 (3 g) as pale yellow liquid.

Biological activity
In vitro HSD11p1 inhibition assay:
CHO cells were maintained in Dulbecco's modified Eagle's medium/nutrient mixture F-12 containing 5% fetal bovine serum (v/v) and 2 mM glutamine. Cells were cultured at 37°C with 5% CO2. For transient expression of human full length HSD11β1 expression vector (OriGene Technologies), cells were seeded at a density of 2 x105 cells/well in a 6-well plate. Transfection was done using Turbofectin8 reagent (OriGene Technologies), according to the protocol provided with the reagent. After 24 hours post-transfection, cells were trypsinized and pooled together before they were re-seeding to 96-well plate at a density of 40000 cells/well. 24 hours after re-seeding, cells were incubated with 200 nM cortisone + 500uM NADPH (or along with small molecule inhibitors) overnight. The enzymatic activity or inhibition of enzyme activity was measured by estimating the conversion of cortisone to Cortisol by LC/MS-MS method. The IC50 in nM was calculated from an 8 point log scale of concentration versus inhibition.

The results of the biological testing are shown in table 1:
