Title: TEXT DISAMBIGUATION EMPLOYING ADVANCED TEXT CASE FEATURE

Abstract: A handheld electronic device includes a reduced QWERTY keyboard and is enabled with disambiguation software. The device provides an improved text case feature. The device provides output in the form of a default output and a number of variants. The output is based largely upon the frequency, i.e., the likelihood that a user intended a particular output, but various features of the device provide additional variants that are not based solely on frequency and rather are provided by various logic structures resident on the device. The device enables editing during text entry and also provides a learning function that allows the disambiguation function to adapt to provide a customized experience for the user. The disambiguation function can be selectively disabled and an alternate keystroke interpretation system provided. Additionally, the device can facilitate the selection of variants by displaying a graphic of a special <NEXT> key of the keypad that enables a user to progressively select variants generally without changing the position of the user's hands on the device. If a field into which text is being entered is determined to be a special input field, a disambiguated result can be sought first from a predetermined data source prior to seeking results from other data sources on the device.

HANDHELD ELECTRONIC DEVICE WITH TEXT DISAMBIGUATION
EMPLOYING ADVANCED TEXT CASE FEATURE

BACKGROUND OF THE INVENTION

Field of the Invention

The invention relates generally to handheld electronic devices and, more particularly, to a handheld electronic device having a reduced keyboard and an input disambiguation function, and also relates to an associated method.

Background Information

Numerous types of handheld electronic devices are known. Examples of such handheld electronic devices include, for instance, personal data assistants (PDAs), handheld computers, two-way pagers, cellular telephones, and the like. Many handheld electronic devices also feature wireless communication capability, although many such handheld electronic devices are stand-alone devices that are functional without communication with other devices.

Such handheld electronic devices are generally intended to be portable, and thus are of a relatively compact configuration in which keys and other input structures often perform multiple functions under certain circumstances or may otherwise have multiple aspects or features assigned thereto. With advances in technology, handheld electronic devices are built to have progressively smaller form factors yet have progressively greater numbers of applications and features resident thereon. As a practical matter, the keys of a keypad can only be reduced to a certain small size before the keys become relatively unusable. In order to enable text entry, however, a keypad must be capable of entering all twenty-six letters of the Latin alphabet, for instance, as well as appropriate punctuation and other symbols.

One way of providing numerous letters in a small space has been to provide a "reduced keyboard" in which multiple letters, symbols, and/or digits, and the like, are assigned to any given key. For example, a touch-tone telephone includes a reduced keypad by providing twelve keys, of which ten have digits thereon, and of these ten keys eight have Latin letters assigned thereto. For instance, one of the keys includes the digit "2" as well as the letters "A", "B", and "C". Other known reduced keyboards have included other arrangements of keys, letters, symbols, digits, and the like. Since a single
actuation of such a key potentially could be intended by the user to refer to any of the letters “A”, “B”, and “C”, and potentially could also be intended to refer to the digit “2”, the input generally is an ambiguous input and is in need of some type of disambiguation in order to be useful for text entry purposes.

In order to enable a user to make use of the multiple letters, digits, and the like on any given key, numerous keystroke interpretation systems have been provided. For instance, a “multi-tap” system allows a user to substantially unambiguously specify a particular linguistic element on a key by pressing the same key a number of times equivalent to the position of the desired linguistic element on the key. For example, on the aforementioned telephone key that includes the letters “ABC”, and the user desires to specify the letter “C”, the user will press the key three times. While such multi-tap systems have been generally effective for their intended purposes, they nevertheless can require a relatively large number of key inputs compared with the number of linguistic elements that ultimately are output.

Another exemplary keystroke interpretation system would include key chording, of which various types exist. For instance, a particular linguistic element can be entered by pressing two keys in succession or by pressing and holding first key while pressing a second key. Still another exemplary keystroke interpretation system would be a “press-and-hold / press-and-release” interpretation function in which a given key provides a first result if the key is pressed and immediately released, and provides a second result if the key is pressed and held for a short period of time. While they systems have likewise been generally effective for their intended purposes, such systems also have their own unique drawbacks.

Another keystroke interpretation system that has been employed is a software-based text disambiguation function. In such a system, a user typically presses keys to which one or more linguistic elements have been assigned, generally pressing each key one time for each desired letter, and the disambiguation software attempt to predict the intended input. Numerous such systems have been proposed, and while many have been generally effective for their intended purposes, shortcomings still exist.

It would be desirable to provide an improved handheld electronic device with a reduced keyboard that seeks to mimic a QWERTY keyboard experience or other particular keyboard experience. Such an improved handheld electronic device might also
desirably be configured with enough features to enable text entry and other tasks with relative ease.

**SUMMARY OF THE INVENTION**

In view of the foregoing, an improved handheld electronic device includes a keypad in the form of a reduced QWERTY keyboard and is enabled with disambiguation software. The device provides an improved text case feature. As a user enters keystrokes, the device provides output in the form of a default output and a number of variants from which a user can choose. The output is based largely upon the frequency, *i.e.*, the likelihood that a user intended a particular output, but various features of the device provide additional variants that are not based solely on frequency and rather are provided by various logic structures resident on the device. The device enables editing during text entry and also provides a learning function that allows the disambiguation function to adapt to provide a customized experience for the user. In certain predefined circumstances, the disambiguation function can be selectively disabled and an alternate keystroke interpretation system provided. Additionally, the device can facilitate the selection of variants by displaying a graphic of a special <NEXT> key of the keypad that enables a user to progressively select variants generally without changing the position of the user’s hands on the device. If a field into which text is being entered is determined to be a special input field, a disambiguated result can be sought first from a predetermined data source prior to seeking results from other data sources on the device.

Accordingly, an aspect of the invention is to provide an improved handheld electronic device and an associated method, with the handheld electronic device including a reduced keyboard that seeks to simulate a QWERTY keyboard experience or another particular keyboard experience.

Another aspect of the invention is to provide an improved handheld electronic devices and an associated method that provide a text input disambiguation function.

Another aspect of the invention is to provide an improved handheld electronic device and an associated method that employ a disambiguation function that, responsive to an ambiguous input, provides a number of proposed outputs according to relative frequency.

Another aspect of the invention is to provide an improved handheld electronic device and an associated method that provide a number of proposed outputs that can be
based upon relative frequency and/or can result from various logic structures resident on the device.

Another aspect of the invention is to provide an improved handheld electronic device and an associated method that enable a custom experience by a user based upon various learning features and other features.

Another aspect of the invention is to provide an improved handheld electronic device and an associated method that employ a disambiguation function that can be selectively disabled in certain predefined circumstances.

Another aspect of the invention is to provide an improved handheld electronic device and an associated method, wherein the handheld electronic device includes an input apparatus which facilitates the selection of variants with relative ease.

Another aspect of the invention is to provide an improved handheld electronic device and an associated method that employ a disambiguation function to disambiguate text input from a reduced QWERTY keyboard or other keyboard and that allow editing of the text input.

Another aspect of the invention is to provide an improved handheld electronic device and an associated method that employ a disambiguation function to disambiguate text input in a fashion that can search predetermined data sources for disambiguation data prior to searching other data sources if the input field is determined to be a special input field.

Accordingly, an aspect of the invention is to provide an improved method of disambiguating an input into a handheld electronic device. The handheld electronic device includes an input apparatus, an output apparatus, and a processor apparatus including a memory having a plurality of objects stored therein. The plurality of objects include a plurality of language objects, with each language object of at least a portion of the plurality of language objects comprising at least a first linguistic element. The input apparatus includes a plurality of input members, with each of at least a portion of the input members of the plurality of input members having a plurality of linguistic elements assigned thereto. The general nature of the method can be stated as including detecting an ambiguous input including a number of input member actuations of a number of the input members of the plurality of input members, with each of at least a portion of the input members of the number of input members including a number of linguistic elements assigned thereto, and with at least one of the input members of the number of
input members having a plurality of linguistic elements assigned thereto. The method
further includes generating a number of prefix objects corresponding with the ambiguous
input, with each prefix object of the number of prefix objects including a number of the
linguistic elements of the number of the input members of the ambiguous input. The
method also includes, for at least a first prefix object of the number of prefix objects,
identifying at least a pair of language objects of the plurality of language objects
corresponding with the at least a first prefix object, with at least a portion of a first
language object of the at least a pair of language objects having a first case makeup
comprising a number of case elements, with at least a portion of a second language object
of the at least a pair of language objects having a second case makeup comprising a
number of case elements, and with the first case makeup and the second case makeup
being different than one another. The method also includes outputting the at least a first
prefix object in accordance with the first case makeup and outputting the at least a first
prefix object in accordance with the second case makeup.

Another aspect of the invention is to provide an improved method of
disambiguating an input into a handheld electronic device. The handheld electronic
device includes an input apparatus, an output apparatus, and a processor apparatus
including a memory having a plurality of objects stored therein. The plurality of objects
include a plurality of language objects. Each language object of at least a portion of the
plurality of language objects comprises at least a first linguistic element. The input
apparatus includes a plurality of input members, with each of at least a portion of the
input members of the plurality of input members having a plurality of linguistic elements
assigned thereto. The general nature of the method can be stated as including detecting
an ambiguous input including a number of input member actuations of a number of the
input members of the plurality of input members, with each of at least a portion of the
input members of the number of input members including a number of linguistic
elements assigned thereto, with at least one of the input members of the number of input
members having a plurality of linguistic elements assigned thereto, and with the
ambiguous input having an input case makeup comprising a number of case elements.
The method also includes generating a number of prefix objects corresponding with the
ambiguous input, with each prefix object of the number of prefix objects including a
number of the linguistic elements of the number of the input members of the ambiguous
input. The method also includes, for at least a first prefix object of the number of prefix

objects, identifying at least a pair of language objects of the plurality of language objects corresponding with the at least a first prefix object, with at least a portion of a first language object of the at least a pair of language objects having a first case makeup comprising a number of case elements, with at least a portion of a second language object of the at least a pair of language objects having a second case makeup comprising a number of case elements, and with the first case makeup and the second case makeup being different than one another. The method further includes determining that at least a portion of the input case makeup including a case element that is upper case corresponds with at least a portion of one of the first case makeup and the second case makeup, and outputting the at least a first prefix object in accordance with the one of the first case makeup and the second case makeup.

Another aspect of the invention is to provide an improved method of disambiguating an input into a handheld electronic device. The handheld electronic device includes an input apparatus, an output apparatus, and a processor apparatus including a memory having a plurality of objects stored therein, with the plurality of objects including a plurality of language objects. Each language object of at least a portion of the plurality of language objects comprises at least a first linguistic element. The input apparatus includes a plurality of input members, with each of at least a portion of the input members of the plurality of input members having a plurality of linguistic elements assigned thereto. The general nature of the method can be stated as including detecting an ambiguous input including a number of input member actuations of a number of the input members of the plurality of input members, with each of at least a portion of the input members of the number of input members including a number of linguistic elements assigned thereto, and with at least one of the input members of the number of input members having a plurality of linguistic elements assigned thereto. The method further includes generating a number of prefix objects corresponding with the ambiguous input, with each prefix object of the number of prefix objects including a number of the linguistic elements of the number of the input members of the ambiguous input, and with the ambiguous input having an input case makeup comprising a number of case elements. The method further includes, for a prefix object of the number of prefix objects, identifying a language object of the plurality of language objects that corresponds therewith, with at least a portion of the identified language object having a stored case makeup comprising a number of case elements, and with at least a portion of
the input case makeup and at least a portion of the stored case makeup being different
than one another. The method further includes outputting as a variant the prefix object in
accordance with the stored case makeup.

DESCRIPTION OF THE PREFERRED EMBODIMENT

An improved handheld electronic device 4 is indicated generally in Fig. 1 and is depicted schematically in Fig. 2. The exemplary handheld electronic device 4 includes a housing 6 upon which are disposed a processor unit that includes an input apparatus 8, an output apparatus 12, a processor 16, a memory 20, and at least a first routine. The processor 16 may be, for instance, and without limitation, a microprocessor (μP) and is responsive to inputs from the input apparatus 8 and provides output signals to the output apparatus 12. The processor 16 also interfaces with the memory 20. Examples of handheld electronic devices are included in U.S. Patent Nos. 6,452,588 and 6,489,950.
As can be understood from Fig. 1, the input apparatus 8 includes a keypad 24 and a thumbwheel 32. As will be described in greater detail below, the keypad 24 is in the exemplary form of a reduced QWERTY keyboard including a plurality of keys 28 that serve as input members. It is noted, however, that the keypad 24 may be of other configurations, such as an AZERTY keyboard, a QWERTZ keyboard, or other keyboard arrangement, whether presently known or unknown, and either reduced or not reduced. As employed herein, the expression "reduced" and variations thereof in the context of a keyboard, a keypad, or other arrangement of input members, shall refer broadly to an arrangement in which at least one of the input members has assigned thereto a plurality of linguistic elements such as, for example, linguistic elements in the set of Latin letters, whereby an actuation of the at least one of the input members, without another input in combination therewith, is an ambiguous input since it could refer to more than one of the plurality of linguistic elements assigned thereto. As employed herein, the expression "linguistic element" and variations thereof shall refer broadly to any element that itself can be a language object or from which a language object can be constructed, identified, or otherwise obtained, and thus would include, for example and without limitation, linguistic elements, letters, strokes, ideograms, phonemes, morphemes, digits, and the like. As employed herein, the expression "language object" and variations thereof shall refer broadly to any type of object that may be constructed, identified, or otherwise obtained from one or more linguistic elements, that can be used alone or in combination to generate text, and that would include, for example and without limitation, words, shortcuts, symbols, ideograms, and the like.

The system architecture of the handheld electronic device 4 advantageously is organized to be operable independent of the specific layout of the keypad 24. Accordingly, the system architecture of the handheld electronic device 4 can be employed in conjunction with virtually any keypad layout substantially without requiring any meaningful change in the system architecture. It is further noted that certain of the features set forth herein are usable on either or both of a reduced keyboard and a non-reduced keyboard.

The keys 28 are disposed on a front face of the housing 6, and the thumbwheel 32 is disposed at a side of the housing 6. The thumbwheel 32 can serve as another input member and is both rotatable, as is indicated by the arrow 34, to provide selection inputs.
to the processor 16, and also can be pressed in a direction generally toward the housing 6, as is indicated by the arrow 38, to provide another selection input to the processor 16.

Among the keys 28 of the keypad 24 are a <NEXT> key 40 and an <ENTER> key 44. The <NEXT> key 40 can be pressed to provide a selection input to the processor 16 and provides substantially the same selection input as is provided by a rotational input of the thumbwheel 32. Since the <NEXT> key 40 is provided adjacent a number of the other keys 28 of the keypad 24, the user can provide a selection input to the processor 16 substantially without moving the user's hands away from the keypad 24 during a text entry operation. As will be described in greater detail below, the <NEXT> key 40 additionally and advantageously includes a graphic 42 disposed thereon, and in certain circumstances the output apparatus 12 also displays a displayed graphic 46 thereon to identify the <NEXT> key 40 as being able to provide a selection input to the processor 16. In this regard, the displayed graphic 46 of the output apparatus 12 is substantially similar to the graphic 42 on the <NEXT> key and thus identifies the <NEXT> key 40 as being capable of providing a desirable selection input to the processor 16.

As can further be seen in Fig. 1, many of the keys 28 include a number of linguistic elements 48 disposed thereon. As employed herein, the expression "a number of" and variations thereof shall refer broadly to any quantity, including a quantity of one, and in certain circumstances herein can also refer to a quantity of zero. In the exemplary depiction of the keypad 24, many of the keys 28 include two linguistic elements, such as including a first linguistic element 52 and a second linguistic element 56 assigned thereto.

One of the keys 28 of the keypad 24 includes as the linguistic elements 48 thereof the letters "Q" and "W", and an adjacent key 28 includes as the linguistic elements 48 thereof the letters "E" and "R". It can be seen that the arrangement of the linguistic elements 48 on the keys 28 of the keypad 24 is generally of a QWERTY arrangement, albeit with many of the keys 28 including two of the linguistic elements 28.

The output apparatus 12 includes a display 60 upon which can be provided an output 64. An exemplary output 64 is depicted on the display 60 in Fig. 1. The output 64 includes a text component 68 and a variant component 72. The variant component 72 includes a default portion 76 and a variant portion 80. The display also includes a caret 84 that depicts generally where the next input from the input apparatus 8 will be received.
The text component 68 of the output 64 provides a depiction of the default portion 76 of the output 64 at a location on the display 60 where the text is being input. The variant component 72 is disposed generally in the vicinity of the text component 68 and provides, in addition to the default proposed output 76, a depiction of the various alternate text choices, i.e., alternates to the default proposed output 76, that are proposed by an input disambiguation function in response to an input sequence of key actuations of the keys 28.

As will be described in greater detail below, the default portion 76 is proposed by the disambiguation function as being the most likely disambiguated interpretation of the ambiguous input provided by the user. The variant portion 80 includes a predetermined quantity of alternate proposed interpretations of the same ambiguous input from which the user can select, if desired. The displayed graphic 46 typically is provided in the variant component 72 in the vicinity of the variant portion 80, although it is understood that the displayed graphic 46 could be provided in other locations and in other fashions without departing from the concept of the invention. It is also noted that the exemplary variant portion 80 is depicted herein as extending vertically below the default portion 76, but it is understood that numerous other arrangements could be provided without departing from the concept of the invention.

Among the keys 28 of the keypad 24 additionally is a <DELETE> key 86 that can be provided to delete a text entry. As will be described in greater detail below, the <DELETE> key 86 can also be employed in providing an alternation input to the processor 16 for use by the disambiguation function.

The memory 20 is depicted schematically in Fig. 2A. The memory 20 can be any of a variety of types of internal and/or external storage media such as, without limitation, RAM, ROM, EPROM(s), EEPROM(s), and the like that provide a storage register for data storage such as in the fashion of an internal storage area of a computer, and can be volatile memory or nonvolatile memory. The memory 20 additionally includes a number of routines depicted generally with the numeral 22 for the processing of data. The routines 22 can be in any of a variety of forms such as, without limitation, software, firmware, and the like. As will be explained in greater detail below, the routines 22 include the aforementioned disambiguation function as an application, as well as other routines.
As can be understood from Fig. 2A, the memory 20 additionally includes data stored and/or organized in a number of tables, sets, lists, and/or otherwise. Specifically, the memory 20 includes a generic word list 88, a new words database 92, and a frequency learning database 96. Stored within the various areas of the memory 20 are a number of language objects 100 and frequency objects 104. The language objects 100 generally are each associated with an associated frequency object 104. The language objects 100 include, in the present exemplary embodiment, a plurality of word objects 108 and a plurality of N-gram objects 112. The word objects 108 are generally representative of complete words within the language or custom words stored in the memory 20. For instance, if the language stored in the memory is, for example, English, generally each word object 108 would represent a word in the English language or would represent a custom word.

Associated with substantially each word object 108 is a frequency object 104 having frequency value that is indicative of the relative frequency within the relevant language of the given word represented by the word object 108. In this regard, the generic word list 88 includes a corpus of word objects 108 and associated frequency objects 104 that together are representative of a wide variety of words and their relative frequency within a given vernacular of, for instance, a given language. The generic word list 88 can be derived in any of a wide variety of fashions, such as by analyzing numerous texts and other language sources to determine the various words within the language sources as well as their relative probabilities, i.e., relative frequencies, of occurrences of the various words within the language sources.

The N-gram objects 112 stored within the generic word list 88 are short strings of linguistic elements within the relevant language typically, for example, one to three linguistic elements in length, and typically represent word fragments within the relevant language, although certain of the N-gram objects 112 additionally can themselves be words. However, to the extent that an N-gram object 112 also is a word within the relevant language, the same word likely would be separately stored as a word object 108 within the generic word list 88. As employed herein, the expression “string” and variations thereof shall refer broadly to an object having one or more linguistic elements or components, and can refer to any of a complete word, a fragment of a word, a custom word or expression, and the like.
In the present exemplary embodiment of the handheld electronic device 4, the N-gram objects 112 include 1-gram objects, i.e., string objects that are one linguistic element in length, 2-gram objects, i.e., string objects that are two linguistic elements in length, and 3-gram objects, i.e., string objects that are three linguistic elements in length, all of which are collectively referred to as N-grams 112. Substantially each N-gram object 112 in the generic word list 88 is similarly associated with an associated frequency object 104 stored within the generic word list 88, but the frequency object 104 associated with a given N-gram object 112 has a frequency value that indicates the relative probability that the linguistic element string represented by the particular N-gram object 112 exists at any location within any word of the relevant language. The N-gram objects 112 and the associated frequency objects 104 are a part of the corpus of the generic word list 88 and are obtained in a fashion similar to the way in which the word object 108 and the associated frequency objects 104 are obtained, although the analysis performed in obtaining the N-gram objects 112 will be slightly different because it will involve analysis of the various linguistic element strings within the various words instead of relying primarily on the relative occurrence of a given word.

The present exemplary embodiment of the handheld electronic device 4, with its exemplary language being the English language, includes twenty-six 1-gram N-gram objects 112, i.e., one 1-gram object for each of the twenty-six letters in the Latin alphabet upon which the English language is based, and further includes 676 2-gram N-gram objects 112, i.e., twenty-six squared, representing each two-letter permutation of the twenty-six letters within the Latin alphabet.

The N-gram objects 112 also include a certain quantity of 3-gram N-gram objects 112, primarily those that have a relatively high frequency within the relevant language. The exemplary embodiment of the handheld electronic device 4 includes fewer than all of the three-letter permutations of the twenty-six letters of the Latin alphabet due to considerations of data storage size, and also because the 2-gram N-gram objects 112 can already provide a meaningful amount of information regarding the relevant language. As will be set forth in greater detail below, the N-gram objects 112 and their associated frequency objects 104 provide frequency data that can be attributed to linguistic element strings for which a corresponding word object 108 cannot be identified or has not been identified, and typically is employed as a fallback data source, although this need not be exclusively the case.
In the present exemplary embodiment, the language objects 100 and the frequency objects 104 are maintained substantially inviolate in the generic word list 88, meaning that the basic language corpus remains substantially unaltered within the generic word list 88, and the learning functions that are provided by the handheld electronic device 4 and that are described below operate in conjunction with other object that are generally stored elsewhere in memory 20, such as, for example, in the new words database 92 and the frequency learning database 96.

The new words database 92 and the frequency learning database 96 store additional word objects 108 and associated frequency objects 104 in order to provide to a user a customized experience in which words and the like that are used relatively more frequently by a user will be associated with relatively higher frequency values than might otherwise be reflected in the generic word list 88. More particularly, the new words database 92 includes word objects 108 that are user-defined and that generally are not found among the word objects 108 of the generic word list 88. Each word object 108 in the new words database 92 has associated therewith an associated frequency object 104 that is also stored in the new words database 92. The frequency learning database 96 stores word objects 108 and associated frequency objects 104 that are indicative of relatively more frequent usage of such words by a user than would be reflected in the generic word list 88. As such, the new words database 92 and the frequency learning database 96 provide two learning functions, that is, they together provide the ability to learn new words as well the ability to learn altered frequency values for known words.

Figs. 3a and 3b depicts in an exemplary fashion the general operation of certain aspects of the disambiguation function of the handheld electronic device 4. Additional features, functions, and the like are depicted and described elsewhere.

An input is detected, as at 204, and the input can be any type of actuation or other operation as to any portion of the input apparatus 8. A typical input would include, for instance, an actuation of a key 28 having a number of linguistic elements 48 thereon, or any other type of actuation or manipulation of the input apparatus 8.

Upon detection at 204 of an input, a timer is reset at 208. The use of the timer will be described in greater detail below.

The disambiguation function then determines, as at 212, whether the current input is an operational input, such as a selection input, a delimiter input, a movement input, an alternation input, or, for instance, any other input that does not constitute an actuation of
a key 28 having a number of linguistic elements 48 thereon. If the input is determined at
212 to not be an operational input, processing continues at 216 by adding the input to the
current input sequence which may or may not already include an input.

Many of the inputs detected at 204 are employed in generating input sequences as
to which the disambiguation function will be executed. An input sequence is build up in
each “session” with each actuation of a key 28 having a number of linguistic elements 48
thereon. Since an input sequence typically will be made up of at least one actuation of a
key 28 having a plurality of linguistic elements 48 thereon, the input sequence will be
ambiguous. When a word, for example, is completed the current session is ended and a
new session is initiated.

An input sequence is gradually built up on the handheld electronic device 4 with
each successive actuation of a key 28 during any given session. Specifically, once a
delimiter input is detected during any given session, the session is terminated and a new
session is initiated. Each input resulting from an actuation of one of the keys 28 having a
number of the linguistic elements 48 associated therewith is sequentially added to the
current input sequence. As the input sequence grows during a given session, the
disambiguation function generally is executed with each actuation of a key 28, i.e., and
input, and as to the entire input sequence. Stated otherwise, within a given session, the
growing input sequence is attempted to be disambiguated as a unit by the disambiguation
function with each successive actuation of the various keys 28.

Once a current input representing a most recent actuation of the one of the keys
28 having a number of the linguistic elements 48 assigned thereto has been added to the
current input sequence within the current session, as at 216 in Fig. 3a, the disambiguation
function generates, as at 220, substantially all of the permutations of the linguistic
elements 48 assigned to the various keys 28 that were actuated in generating the input
sequence. In this regard, the “permutations” refer to the various strings that can result
from the linguistic elements 48 of each actuated key 28 limited by the order in which the
keys 28 were actuated. The various permutations of the linguistic elements in the input
sequence are employed as prefix objects.

For instance, if the current input sequence within the current session is the
ambiguous input of the keys “AS” and “OP”, the various permutations of the first
linguistic element 52 and the second linguistic element 56 of each of the two keys 28,
when considered in the sequence in which the keys 28 were actuated, would be “SO”,

15
“SP”, “AP”, and “AO”, and each of these is a prefix object that is generated, as at 220, with respect to the current input sequence. As will be explained in greater detail below, the disambiguation function seeks to identify for each prefix object one of the word objects 108 for which the prefix object would be a prefix.

The method of the invention also determines, as at 222, whether or not the input field into which language is being entered is a “special” input field. In this regard, a special input field is one to which particular stored data can be of particular relevance, and such particular stored data and is therefore sought to be obtained first before obtaining other data. In effect, therefore, the method can, for instance, provide proposed output results that are particularly suited to the input field. As such, the output results are more likely to be the results desired by the user than otherwise might be the case if all of the data sources were searched in the usual fashion to provide proposed disambiguation results. If the input field is determined by the method to be special, a special flag is set and processing is transferred, as at 226, for further processing, as at 604 in Fig. 6A, as will be discussed in greater detail below.

If, however, the input field is determined as at 222 to not be special, processing continues at 224. For each generated prefix object, the memory 20 is consulted, as at 224, to identify, if possible, for each prefix object one of the word objects 108 in the memory 20 that corresponds with the prefix object, meaning that the sequence of letters represented by the prefix object would be either a prefix of the identified word object 108 or would be substantially identical to the entirety of the word object 108. Further in this regard, the word object 108 that is sought to be identified is the highest frequency word object 108. That is, the disambiguation function seeks to identify the word object 108 that corresponds with the prefix object and that also is associated with a frequency object 104 having a relatively higher frequency value than any of the other frequency objects 104 associated with the other word objects 108 that correspond with the prefix object.

It is noted in this regard that the word objects 108 in the generic word list 88 are generally organized in data tables that correspond with the first two letters of various words. For instance, the data table associated with the prefix “CO” would include all of the words such as “CODE”, “COIN”, “COMMUNICATION”, and the like. Depending upon the quantity of word objects 108 within any given data table, the data table may additionally include sub-data tables within which word objects 108 are organized by prefixes that are three linguistic elements or more in length. Continuing onward with the
foresgoing example, if the “CO” data table included, for instance, more than 256 word objects 108, the “CO” data table would additionally include one or more sub-data tables of word objects 108 corresponding with the most frequently appearing three-letter prefixes. By way of example, therefore, the “CO” data table may also include a “COM” sub-data table and a “CON” sub-data table. If a sub-data table includes more than the predetermined number of word objects 108, for example a quantity of 256, the sub-data table may include further sub-data tables, such as might be organized according to a four letter prefixes. It is noted that the aforementioned quantity of 256 of the word objects 108 corresponds with the greatest numerical value that can be stored within one byte of the memory 20.

Accordingly, when, at 224, each prefix object is sought to be used to identify a corresponding word object 108, and for instance the instant prefix object is “AP”, the “AP” data table will be consulted. Since all of the word objects 108 in the “AP” data table will correspond with the prefix object “AP”, the word object 108 in the “AP” data table with which is associated a frequency object 104 having a frequency value relatively higher than any of the other frequency objects 104 in the “AP” data table is identified. The identified word object 108 and the associated frequency object 104 are then stored in a result register that serves as a result of the various comparisons of the generated prefix objects with the contents of the memory 20.

It is noted that one or more, or possibly all, of the prefix objects will be prefix objects for which a corresponding word object 108 is not identified in the memory 20. Such prefix objects are considered to be orphan prefix objects and are separately stored or are otherwise retained for possible future use. In this regard, it is noted that many or all of the prefix objects can become orphan object if, for instance, the user is trying to enter a new word or, for example, if the user has mis-keyed and no word corresponds with the mis-keyed input.

Once the result has been obtained at 224, the disambiguation function determines, as at 228, whether artificial variants should be generated. In order to determine the need for artificial variants, the process at 228 branches, as at 230, to the artificial variant process depicted generally in Fig. 4 and beginning with the numeral 304. The disambiguation function then determines, as at 308, whether any of the prefix objects in the result correspond with what had been the default output 76 prior to detection of the current key input. If a prefix object in the result corresponds with the previous default
output, this means that the current input sequence corresponds with a word object 108 and, necessarily, the previous default output also corresponded with a word object 108 during the previous disambiguation cycle within the current session.

The next point of analysis is to determine, as at 310, whether the previous default output was made the default output because of a selection input, such as would have causes the setting of a flag, such as at 254 of Fig. 3b, discussed in greater detail below. In the event that the previous default output was not the result of a selection input, no artificial variants are needed, and the process returns, as at 312, to the main process at 232. However, if it is determined at 310 that the previous default output was the result of a selection input, then artificial variants are generated, as at 316.

More specifically, each of the artificial variants generated at 316 include the previous default output plus one of the linguistic elements 48 assigned to the key 28 of the current input. As such, if the key 28 of the current input has two linguistic elements, i.e., a first linguistic element 52 and a second linguistic element 56, two artificial variants will be generated at 316. One of the artificial variants will include the previous default output plus the first linguistic element 52. The other artificial variant will include the previous default output plus the second linguistic element 56.

However, if it is determined at 308 that none of the prefix objects in the result correspond with the previous default output, it is next necessary to determine, as at 314, whether the previous default output had corresponded with a word object 108 during the previous disambiguation cycle within the current session. If the answer to the inquiry at 314 is no, it is still necessary to determine, as at 318, whether the previous default output was made the default output because of a selection input, such as would have causes the setting of the flag. In the event that the previous default output was not the result of a selection input, no artificial variants are needed, and the process returns, as at 312, to the main process at 232. However, if it is determined at 318 that the previous default output was the result of a selection input, then artificial variants are generated, as at 316.

On the other hand, if it is determined that the answer to the inquiry at 314 is yes, meaning that the previous default output had corresponded with a word object, but with the current input the previous default output combined with the current input has ceased to correspond with any word object 108, then artificial variants are generated, again as at 316.
After the artificial variants are generated at 316, the method then determines, as at 320, whether the result includes any prefix objects at all. If not, processing returns, as at 312, to the main process at 232. However, if it is determined at 320 that the result includes at least a first prefix object, meaning that the current input sequence corresponds with a word object 108, processing is transferred to 324 where an additional artificial variant is created. Specifically, the prefix object of the result with which is associated the frequency object 104 having the relatively highest frequency value among the other frequency objects 104 in the result is identified, and the artificial variant is created by deleting the final linguistic element from the identified prefix object and replacing it with an opposite linguistic element 48 on the same key 28 of the current input that generated the final linguistic element 48 of the identified prefix object. In the event that the specific key 28 has more than two linguistic elements 48 assigned thereto, the specific key 28 will be considered to have a plurality of opposite linguistic elements 48. Moreover, each such opposite linguistic element 48 will be used to generate an additional artificial variant.

Once the need for artificial variants has been identified, as at 228, and such artificial variants have been generated, as in Fig. 4 and as described above, processing continues, as at 232, where duplicate word objects 108 associated with relatively lower frequency values are deleted from the result. Such a duplicate word object 108 could be generated, for instance, by the frequency learning database 96, as will be set forth in greater detail below. If a word object 108 in the result matches one of the artificial variants, the word object 108 and its associated frequency object 104 generally will be removed from the result because the artificial variant will be assigned a preferred status in the output 64, likely in a position preferred to any word object 108 that might have been identified.

Once the duplicate word objects 108 and the associated frequency objects 104 have been removed at 232, the remaining prefix objects are arranged, as at 236, in an output set in decreasing order of frequency value. The orphan prefix objects mentioned above may also be added to the output set, albeit at positions of relatively lower frequency value than any prefix object for which a corresponding word object 108 was found. It is also necessary to ensure that the artificial variants, if they have been created, are placed at a preferred position in the output set. It is understood that artificial variants
may, but need not necessarily be, given a position of preference, i.e., assigned a relatively higher priority or frequency, than prefix objects of the result.

If it is determined, as at 240, that the flag has been set, meaning that a user has made a selection input, either through an express selection input or through an alternation input of a movement input, then the default output 76 is considered to be “locked,” meaning that the selected variant will be the default prefix until the end of the session. If it is determined at 240 that the flag has been set, the processing will proceed to 244 where the contents of the output set will be altered, if needed, to provide as the default output 76 an output that includes the selected prefix object, whether it corresponds with a word object 108 or is an artificial variant. In this regard, it is understood that the flag can be set additional times during a session, in which case the selected prefix associated with resetting of the flag thereafter becomes the “locked” default output 76 until the end of the session or until another selection input is detected.

Processing then continues, as at 248, to an output step after which an output 64 is generated as described above. More specifically, processing proceeds, as at 250, to the subsystem depicted generally in Fig. 6 and described below. Processing thereafter continues at 204 where additional input is detected. On the other hand, if it is determined at 240 that the flag had not been set, then processing goes directly to 248 without the alteration of the contents of the output set at 244.

The handheld electronic device 4 may be configured such that any orphan prefix object that is included in an output 64 but that is not selected with the next input is suspended. This may be limited to orphan prefix objects appearing in the variant portion 80 or may apply to orphan prefix objects anywhere in the output 64. The handheld electronic device 4 may also be configured to similarly suspend artificial variants in similar circumstances. A reason for such suspension is that each such orphan prefix object and/or artificial variant, as appropriate, may spawn a quantity of offspring orphan prefix objects equal to the quantity of linguistic elements 48 on a key 28 of the next input. That is, each offspring will include the parent orphan prefix object or artificial variant plus one of the linguistic elements 48 of the key 28 of the next input. Since orphan prefix objects and artificial variants substantially do not have correspondence with a word object 108, spawned offspring objects from parent orphan prefix objects and artificial variants likewise will not have correspondence with a word object 108. Such suspended orphan prefix objects and/or artificial variants may be considered to be
suspended, as compared with being wholly eliminated, since such suspended orphan prefix objects and/or artificial variants may reappear later as parents of a spawned orphan prefix objects and/or artificial variants, as will be explained below.

If the detected input is determined, as at 212, to be an operational input, processing then continues to determine the specific nature of the operational input. For instance, if it is determined, as at 252, that the current input is a selection input, processing continues at 254. At 254, the word object 108 and the associated frequency object 104 of the default portion 76 of the output 64, as well as the word object 108 and the associated frequency object 104 of the portion of the variant output 80 that was selected by the selection input, are stored in a temporary learning data register. Additionally, the flag is set. Processing then returns to detection of additional inputs as at 204.

If it is determined, as at 260, that the input is a delimiter input, processing continues at 264 where the current session is terminated and processing is transferred, as at 266, to the learning function subsystem, as at 404 of Fig. 5a. A delimiter input would include, for example, the actuation of a <SPACE> key 116, which would both enter a delimiter symbol and would add a space at the end of the word, actuation of the <ENTER> key 44, which might similarly enter a delimiter input and enter a space, and by a translation of the thumbwheel 32, such as is indicated by the arrow 38, which might enter a delimiter input without additionally entering a space.

It is first determined, as at 408, whether the default output at the time of the detection of the delimiter input at 260 matches a word object 108 in the memory 20. If it does not, this means that the default output is a user-created output that should be added to the new words database 92 for future use. In such a circumstance processing then proceeds to 412 where the default output is stored in the new words database 92 as a new word object 108. Additionally, a frequency object 104 is stored in the new words database 92 and is associated with the aforementioned new word object 108. The new frequency object 104 is given a relatively high frequency value, typically within the upper one-fourth or one-third of a predetermined range of possible frequency values.

In this regard, frequency objects 104 are given an absolute frequency value generally in the range of zero to 65,535. The maximum value represents the largest number that can be stored within two bytes of the memory 20. The new frequency object 104 that is stored in the new words database 92 is assigned an absolute frequency value
within the upper one-fourth or one-third of this range, particularly since the new word was used by a user and is likely to be used again.

With further regard to frequency object 104, it is noted that within a given data table, such as the "CO" data table mentioned above, the absolute frequency value is stored only for the frequency object 104 having the highest frequency value within the data table. All of the other frequency objects 104 in the same data table have frequency values stored as percentage values normalized to the aforementioned maximum absolute frequency value. That is, after identification of the frequency object 104 having the highest frequency value within a given data table, all of the other frequency objects 104 in the same data table are assigned a percentage of the absolute maximum value, which represents the ratio of the relatively smaller absolute frequency value of a particular frequency object 104 to the absolute frequency value of the aforementioned highest value frequency object 104. Advantageously, such percentage values can be stored within a single byte of memory, thus saving storage space within the handheld electronic device 4.

Upon creation of the new word object 108 and the new frequency object 104, and storage thereof within the new words database 92, processing is transferred to 420 where the learning process is terminated. Processing is then returned to the main process, as at 204.

If at 408 it is determined that the word object 108 in the default output 76 matches a word object 108 within the memory 20, processing then continues at 416 where it is determined whether the aforementioned flag has been set, such as occurs upon the detection of a selection input, and alternation input, or a movement input, by way of example. If it turns out that the flag has not been set, this means that the user has not expressed a preference for a variant prefix object over a default prefix object, and no need for frequency learning has arisen. In such a circumstance, processing continues at 420 where the learning process is terminated. Processing then returns to the main process at 204.

However, if it is determined at 416 that the flag has been set, the processor 16 retrieves from the temporary learning data register the most recently saved default and variant word objects 108, along with their associated frequency objects 104. It is then determined, as at 428, whether the default and variant word objects 108 had previously been subject of a frequency learning operation. This might be determined, for instance, by determining whether the variant word object 108 and the associated frequency object
104 were obtained from the frequency learning database 96. If the default and variant word objects 108 had not previously been the subject of a frequency learning operation, processing continues, as at 432, where the variant word object 108 is stored in the frequency learning database 96, and a revised frequency object 104 is generated having a frequency value greater than that of the frequency object 104 that previously had been associated with the variant word object 108. In the present exemplary circumstance, i.e., where the default word object 108 and the variant word object 108 are experiencing their first frequency learning operation, the revised frequency object 104 may, for instance, be given a frequency value equal to the sum of the frequency value of the frequency object 104 previously associated with the variant word object 108 plus one-half the difference between the frequency value of the frequency object 104 associated with the default word object 108 and the frequency value of the frequency object 104 previously associated with the variant word object 108. Upon storing the variant word object 108 and the revised frequency object 104 in the frequency learning database 96, processing continues at 420 where the learning process is terminated and processing returns to the main process, as at 204.

If it is determined at 428 that that default word object 108 and the variant word object 108 had previously been the subject of a frequency learning operation, processing continues to 436 where the revised frequency value 104 is instead given a frequency value higher than the frequency value of the frequency object 104 associated with the default word object 108. After storage of the variant word object 108 and the revised frequency object 104 in the frequency learning database 96, processing continues to 420 where the learning process is terminated, and processing then returns to the main process, as at 204.

With further regard to the learning function, it is noted that the learning function additionally detects whether both the default word object 108 and the variant word object 104 were obtained from the frequency learning database 96. In this regard, when word objects 108 are identified, as at 224, for correspondence with generated prefix objects, all of the data sources in the memory are polled for such corresponding word objects 108 and corresponding frequency objects 104. Since the frequency learning database 96 stores word objects 108 that also are stored either in the generic word list 88 or the new words database 92, the word object 108 and the associated frequency object 104 that are obtained from the frequency learning database 96 typically are duplicates of word objects.
108 that have already been obtained from the generic word list 88 or the new words
database 92. However, the associated frequency object 104 obtained from the frequency
learning database 96 typically has a frequency value that is of a greater magnitude than
that of the associated frequency object 104 that had been obtained from the generic word
list 88. This reflects the nature of the frequency learning database 96 as imparting to a
frequently used word object 108 a relatively greater frequency value than it otherwise
would have in the generic word list 88.

It thus can be seen that the learning function indicated in Figs. 5a and 5b and
described above is generally not initiated until a delimiter input is detected, meaning that
learning occurs only once for each session. Additionally, if the final default output is not
a user-defined new word, the word objects 108 that are the subject of the frequency
learning function are the word objects 108 which were associated with the default output
76 and the selected variant output 80 at the time when the selection occurred, rather than
necessarily being related to the object that ultimately resulted as the default output at the
end of the session. Also, if numerous learnable events occurred during a single session,
the frequency learning function operates only on the word objects 108 that were
associated with the final learnable event, i.e., a selection event, an alternation event, or a
movement event, prior to termination of the current session.

With further regard to the identification of various word objects 108 for
correspondence with generated prefix objects, it is noted that the memory 20 can include
a number of additional data sources 99 in addition to the generic word list 88, the new
words database 92, and the frequency learning database 96, all of which can be
considered linguistic sources. An exemplary two other data sources 99 are depicted in
Fig. 2a, it being understood that the memory 20 might include any number of other data
sources 99. The other data sources 99 might include, for example, an address database, a
speed-text database, or any other data source without limitation. An exemplary speed-
text database might include, for example, sets of words or expressions or other data that
are each associated with, for example, a linguistic element string that may be
abbreviated. For example, a speed-text database might associate the string “br” with the
set of words “Best Regards”, with the intention that a user can type the string “br” and
receive the output “Best Regards”.

In seeking to identify word objects 108 that correspond with a given prefix object,
the handheld electronic device 4 may poll all of the data sources in the memory 20. For
instance the handheld electronic device 4 may poll the generic word list 88, the new words database 92, the frequency learning database 96, and the other data sources 99 to identify word objects 108 that correspond with the prefix object. The contents of the other data sources 99 may be treated as word objects 108, and the processor 16 may generate frequency objects 104 that will be associated such word objects 108 and to which may be assigned a frequency value in, for example, the upper one-third or one-fourth of the aforementioned frequency range. Assuming that the assigned frequency value is sufficiently high, the string “br”, for example, would typically be output to the display 60. If a delimiter input is detected with respect to the portion of the output having the association with the word object 108 in the speed-text database, for instance “br”, the user would receive the output “Best Regards”, it being understood that the user might also have entered a selection input as to the exemplary string “br”.

The contents of any of the other data sources 99 may be treated as word objects 108 and may be associated with generated frequency objects 104 having the assigned frequency value in the aforementioned upper portion of the frequency range. After such word objects 108 are identified, the new word learning function can, if appropriate, act upon such word objects 108 in the fashion set forth above.

Again regarding Fig. 3a, when processing proceeds to the filtration step, as at 232, and the duplicate word objects 108 and the associated frequency objects 104 having relatively lower frequency values are filtered, the remaining results may include a variant word object 108 and a default word object 108, both of which were obtained from the frequency learning database 96. In such a situation, it can be envisioned that if a user repetitively and alternately uses one word then the other word, over time the frequency objects 104 associated with such words will increase well beyond the aforementioned maximum absolute frequency value for a frequency object 104. Accordingly, if it is determined that both the default word object 108 and the variant word object 108 in the learning function were obtained from the frequency learning database 96, instead of storing the variant word object 108 in the frequency learning database 96 and associating it with a frequency object 104 having a relatively increased frequency value, instead the learning function stores the default word object 108 and associates it with a revised frequency object 104 having a frequency value that is relatively lower than that of the frequency object 104 that is associated with the variant word object 108. Such a scheme advantageously avoids excessive and unnecessary increases in frequency value.
If it is determined, such as at 268, that the current input is a movement input, such as would be employed when a user is seeking to edit an object, either a completed word or a prefix object within the current session, the caret 84 is moved, as at 272, to the desired location, and the flag is set, as at 276. Processing then returns to where additional inputs can be detected, as at 204.

In this regard, it is understood that various types of movement inputs can be detected from the input device 8. For instance, a rotation of the thumbwheel 32, such as is indicated by the arrow 34 of Fig. 1, could provide a movement input, as could the actuation of the <NEXT> key 40, or other such input, potentially in combination with other devices in the input apparatus 8. In the instance where such a movement input is detected, such as in the circumstance of an editing input, the movement input is additionally detected as a selection input. Accordingly, and as is the case with a selection input such as is detected at 252, the selected variant is effectively locked with respect to the default portion 76 of the output 64. Any default output 76 during the same session will necessarily include the previously selected variant.

In the context of editing, however, the particular displayed object that is being edited is effectively locked except as to the linguistic element that is being edited. In this regard, therefore, the other linguistic elements of the object being edited, i.e., the linguistic elements that are not being edited, are maintained and are employed as a context for identifying additional word objects 108 and the like that correspond with the object being edited. Were this not the case, a user seeking to edit a letter in the middle of a word otherwise likely would see as a new output 64 numerous objects that bear little or no resemblance to the linguistic elements of the object being edited since, in the absence of maintaining such context, an entirely new set of prefix objects including all of the permutations of the linguistic elements of the various keystrokes of the object being edited would have been generated. New word objects 108 would have been identified as corresponding with the new prefix objects, all of which could significantly change the output 64 merely upon the editing of a single linguistic element. By maintaining the other linguistic elements currently in the object being edited, and employing such other linguistic elements as context information, the user can much more easily edit a word that is depicted on the display 60. As will be described below, however, other types of editing can be employed by the user, and different rules regarding locking of portions of prefix objects can be applied in such situations.
In the present exemplary embodiment of the handheld electronic device 4, if it is determined, as at 252, that the input is not a selection input, and it is determined, as at 260, that the input is not a delimiter input, and it is further determined, as at 268, that the input is not a movement input, in the current exemplary embodiment of the handheld electronic device 4 the only remaining operational input generally is a detection of the <DELETE> key 86 of the keys 28 of the keypad 24. Upon detection of the <DELETE> key 86, the final linguistic element of the default output is deleted, as at 280. At this point, the processing generally waits until another input is detected, as at 284. It is then determined, as at 288, whether the new input detected at 284 is the same as the most recent input that was related to the final linguistic element that had just been deleted at 280. If so, the default output 76 is the same as the previous default output, except that the last linguistic element is the opposite linguistic element of the key actuation that generated the last linguistic element. Processing then continues to 292 where learning data, i.e., the word object 108 and the associate frequency object 104 associated with the previous default output 76, as well as the word object 108 and the associate frequency object 104 associated with the new default output 76, are stored in the temporary learning data register and the flag is set. Such a key sequence, i.e., an input, the <DELETE> key 86, and the same input as before, is an alternation input. Such an alternation input replaces the default final linguistic element with an opposite final linguistic element of the key 28 which generated the final linguistic element 48 of the default output 76. The alternation input is treated as a selection input for purposes of locking the default output 76 for the current session, and also triggers the flag which will initiate the learning function upon detection of a delimiter input at 260.

If it turns out, however, that the system detects at 288 that the new input detected at 284 is different than the input immediately prior to detection of the <DELETE> key 86, processing continues at 212 where the input is determined to be either an operational input or an input of a key having one or more linguistic elements 48, and processing continues thereafter.

It is also noted that when the main process reaches the output stage at 248, an additional process is initiated which determines whether the variant component 72 of the output 64 should be initiated. Processing of the additional function is initiated from 248 at element 504 of Fig. 6. Initially, the method at 508 outputs the text component 68 of
the output 64 to the display 60. Further processing determines whether or not the variant component 72 should be displayed.

Specifically, it is determined, as at 512, whether the variant component 72 has already been displayed during the current session. If the variant component 72 has already been displayed, processing continues at 516 where the new variant component 72 resulting from the current disambiguation cycle within the current session is displayed. Processing then returns to a termination point at 520, after which processing returns to the main process at 204. If, however, it is determined at 512 that the variant component 72 has not yet been displayed during the current session, processing continues, as at 524, to determine whether the elapsed time between the current input and the immediately previous input is longer than a predetermined duration. If it is longer, then processing continues at 516 where the variant component 72 is displayed and processing returns, through 520, to the main process, as at 204. However, if it is determined at 524 that the elapsed time between the current input and the immediately previous input is less than the predetermined duration, the variant component 72 is not displayed, and processing returns to the termination point at 520, after which processing returns to the main process, as at 204.

Advantageously, therefore, if a user is entering keystrokes relatively quickly, the variant component 72 will not be output to the display 60, where it otherwise would likely create a visual distraction to a user seeking to enter keystrokes quickly. If at any time during a given session the variant component 72 is output to the display 60, such as if the time between successive inputs exceeds the predetermined duration, the variant component 72 will continue to be displayed throughout that session. However, upon the initiation of a new session, the variant component 72 will be withheld from the display if the user consistently is entering keystrokes relatively quickly.

As mentioned above, in certain circumstances certain data sources can be searched prior to other data sources if the input field is determined, as at 222, to be special. For instance, if the input field is to have a particular type of data input therein, and this particular type of data can be identified and obtained, the disambiguated results will be of a greater degree of relevance to the field and have a higher degree of correspondence with the intent of the user. For instance, a physician’s prescription pad typically includes blank spaces into which are inserted, for instance, a patient’s name, a drug name, and instructions for administering the drug. The physician’s prescription pad
potentially could be automated as an application on the device 4. During entry of the patient’s name, the data source 99 that would most desirably be searched first would be, for instance, a data source 99 listing the names and, for instance, the contact information for the doctor’s patients. Similarly, during entry of the drug name, the data source 99 that would most desirably be searched first would be the data source 99 listing, for instance, names of drugs. By searching these special data sources first, the relevance of the proposed disambiguated results is higher since the results are more likely to be what is intended by the user. If the method obtains an insufficient quantity of results in such a fashion, however, additional results can be obtained in the usual fashion from the other data sources.

As can be seen in Fig. 6A, after processing is transferred to 604 from the main process, the method searches, as at 608, for word objects 108 and frequency objects 104 in whatever data source 99 is determined to correspond with or have some relevance to the special input field. The input field typically will inform the operating system of the device 4 that it typically receives a particular type of input, and the operating system will determine which data source 99 will be searched first in seeking disambiguation results.

The disambiguation results obtained from the special, i.e., predetermined, data source 99 are then filtered, as at 612, to eliminate duplicate results, and the quantity of remaining results are then counted, as at 616, to determine whether the quantity is less than a predetermined number. If the answer to this inquiry is “no”, meaning that a sufficient quantity of results were obtained from the particular data source 99, processing is transferred, as at 620, to the main process at 236.

On the other hand, if it is determined at 616 that insufficient disambiguation results were obtained from the predetermined data source 99, addition results typically will desirably be obtained. For instance, in such a circumstance processing continues, as at 624, to processing at which the prefix results are arranged in order of decreasing frequency value into a special output set. A special flag is set, as at 628, that indicates to the method that the additional disambiguation results that are about to be obtained from the other data sources of the device 4 are to appended to the end of the special output set. Processing is transferred, as at 630, back to the main process at 224, after which additional disambiguation results will be sought from the other data sources on the device 4. With the special flag being set, as at 628, the results that were obtained from the predetermined data source are to be listed ahead of the additional results obtained from
the remaining data sources, even if the additional results are associated with relatively higher frequency values than some of the results from the predetermined data source. The method could, however, be applied in different fashions without departing from the concept of the invention.

An exemplary input sequence is depicted in Figs. 1 and 7-11. In this example, the user is attempting to enter the word “APPLOADER”, and this word presently is not stored in the memory 20. In Fig. 1 the user has already typed the “AS” key 28. Since the data tables in the memory 20 are organized according to two-letter prefixes, the contents of the output 64 upon the first keystroke are obtained from the N-gram objects 112 within the memory. The first keystroke “AS” corresponds with a first N-gram object 112 “S” and an associated frequency object 104, as well as another N-gram object 112 “A” and an associated frequency object 104. While the frequency object 104 associated with “S” has a frequency value greater than that of the frequency object 104 associated with “A”, it is noted that “A” is itself a complete word. A complete word is always provided as the default output 76 in favor of other prefix objects that do not match complete words, regardless of associated frequency value. As such, in Fig. 1, the default portion 76 of the output 64 is “A”.

In Fig. 7, the user has additionally entered the “OP” key 28. The variants are depicted in Fig. 7. Since the prefix object “SO” is also a word, it is provided as the default output 76. In Fig. 8, the user has again entered the “OP” key 28 and has also entered the “L” key 28. It is noted that the exemplary “L” key 28 depicted herein includes only the single linguistic element 48 “L”.

It is assumed in the instant example that no operational inputs have thus far been detected. The default output 76 is “APPL”, such as would correspond with the word “APPLE”. The prefix “APPL” is depicted both in the text component 68, as well as in the default portion 76 of the variant component 72. Variant prefix objects in the variant portion 80 include “APOL”, such as would correspond with the word “APOLOGIZE”, and the prefix “SPOL”, such as would correspond with the word “SPOLIATION”.

It is particularly noted that the additional variants “AOOL”, “AOPL”, “SOPL”, and “SOOL” are also depicted as variants 80 in the variant component 72. Since no word object 108 corresponds with these prefix objects, the prefix objects are considered to be orphan prefix objects for which a corresponding word object 108 was not identified. In this regard, it may be desirable for the variant component 72 to include a specific
quantity of entries, and in the case of the instant exemplary embodiment the quantity is seven entries. Upon obtaining the result at 224, if the quantity of prefix objects in the result is fewer than the predetermined quantity, the disambiguation function will seek to provide additional outputs until the predetermined number of outputs are provided. In the absence of artificial variants having been created, the additional variant entries are provided by orphan prefix objects. It is noted, however, that if artificial variants had been generated, they likely would have occupied a place of preference in favor of such orphan prefix objects, and possibly also in favor of the prefix objects of the result.

It is further noted that such orphan prefix objects may actually be offspring orphan prefix objects from suspended parent orphan prefix objects and/or artificial variants. Such offspring orphan prefix objects can be again output depending upon frequency ranking as explained below, or as otherwise ranked.

The orphan prefix objects are ranked in order of descending frequency with the use of the N-gram objects 112 and the associated frequency objects 104. Since the orphan prefix objects do not have a corresponding word object 108 with an associated frequency object 104, the frequency objects 104 associated with the various N-gram objects 112 must be employed as a fallback.

Using the N-gram objects 112, the disambiguation function first seeks to determine if any N-gram object 112 having, for instance, three linguistic elements is a match for, for instance, a final three linguistic elements of any orphan prefix object. The example of three linguistic elements is given since the exemplary embodiment of the handheld electronic device 4 includes N-gram objects 112 that are an exemplary maximum of the three linguistic elements in length, but it is understood that if the memory 20 included N-gram objects four linguistic elements in length or longer, the disambiguation function typically would first seek to determine whether an N-gram object having the greatest length in the memory 20 matches the same quantity of linguistic elements at the end of an orphan prefix object.

If only one prefix object corresponds in such a fashion to a three linguistic element N-gram object 112, such orphan prefix object is listed first among the various orphan prefix objects in the variant output 80. If additional orphan prefix objects are matched to N-gram objects 112 having three linguistic elements, then the frequency objects 104 associated with such identified N-gram objects 112 are analyzed, and the
matched orphan prefix objects are ranked amongst themselves in order of decreasing frequency.

If it is determined that a match cannot be obtained with an N-gram object 112 having three linguistic elements, then two-linguistic element N-gram objects 112 are employed. Since the memory 20 includes all permutations of two-linguistic element N-gram objects 112, a last two linguistic elements of each orphan prefix object can be matched to a corresponding two-linguistic element N-gram object 112. After such matches are achieved, the frequency objects 104 associated with such identified N-gram objects 112 are analyzed, and the orphan prefix objects are ranked amongst themselves in descending order of frequency value of the frequency objects 104 that were associated with the identified N-gram objects 112. It is further noted that artificial variants can similarly be rank ordered amongst themselves using the N-gram objects 112 and the associated frequency objects 104.

In Fig. 9 the user has additionally entered the “OP” key 28. In this circumstance, and as can be seen in Fig. 9, the default portion 76 of the output 64 has become the prefix object “APOLO” such as would correspond with the word “APOLOGIZE”, whereas immediately prior to the current input the default portion 76 of the output 64 of Fig. 8 was “APPL” such as would correspond with the word “APPLE.” Again, assuming that no operational inputs had been detected, the default prefix object in Fig. 9 does not correspond with the previous default prefix object of Fig. 8. As such, the first artificial variant “APOLP” is generated and in the current example is given a preferred position. The aforementioned artificial variant “APOLP” is generated by deleting the final linguistic element of the default prefix object “APOLO” and by supplying in its place an opposite linguistic element 48 of the key 28 which generated the final linguistic element of the default portion 76 of the output 64, which in the current example of Fig. 9 is “P”, so that the aforementioned artificial variants is “APOLP”.

Furthermore, since the previous default output “APPL” corresponded with a word object 108, such as the word object 108 corresponding with the word “APPLE”, and since with the addition of the current input the previous default output “APPL” no longer corresponds with a word object 108, two additional artificial variants are generated. One artificial variant is “APPLP” and the other artificial variant is “APPLO”, and these correspond with the previous default output “APPL” plus the linguistic elements 48 of
the key 28 that was actuated to generate the current input. These artificial variants are similarly output as part of the variant portion 80 of the output 64.

As can be seen in Fig. 9, the default portion 76 of the output 64 “APOLO” no longer seems to match what would be needed as a prefix for “APPLOADER”, and the user likely anticipates that the desired word “APPLOADER” is not already stored in the memory 20. As such, the user provides a selection input, such as by scrolling with the thumbwheel 32, or by actuating the <NEXT> key 40, until the variant string “APPLO” is highlighted. The user then continues typing and enters the “AS” key.

The output 64 of such action is depicted in Fig. 10. Here, the string “APPLOA” is the default portion 76 of the output 64. Since the variant string “APPLO” became the default portion 76 of the output 64 (not expressly depicted herein) as a result of the selection input as to the variant string “APPLO”, and since the variant string “APPLO” does not correspond with a word object 108, the linguistic element strings “APPLOA” and “APPLOS” were created as an artificial variants. Additionally, since the previous default of Fig. 9, “APOLO” previously had corresponded with a word object 108, but now is no longer in correspondence with the default portion 76 of the output 64 of Fig. 10, the additional artificial variants of “APOLOA” and “APOLOS” were also generated. Such artificial variants are given a preferred position in favor of the three displayed orphan prefix objects.

Since the current input sequence in the example no longer corresponds with any word object 108, the portions of the method related to attempting to find corresponding word objects 108 are not executed with further inputs for the current session. That is, since no word object 108 corresponds with the current input sequence, further inputs will likewise not correspond with any word object 108. Avoiding the search of the memory 20 for such nonexistent word objects 108 saves time and avoids wasted processing effort.

As the user continues to type, the user ultimately will successfully enter the word “APPLOADER” and will enter a delimiter input. Upon detection of the delimiter input after the entry of “APPLOADER”, the learning function is initiated. Since the word “APPLOADER” does not correspond with a word object 108 in the memory 20, a new word object 108 corresponding with “APPLOADER” is generated and is stored in the new words database 92, along with a corresponding new frequency object 104 which is given an absolute frequency in the upper, say, one-third or one-fourth of the possible frequency range. In this regard, it is noted that the new words database 92 and the
frequency learning database 96 are generally organized in two-linguistic element prefix
data tables similar to those found in the generic word list 88. As such, the new frequency
object 104 is initially assigned an absolute frequency value, but upon storage the absolute
frequency value, if it is not the maximum value within that data table, will be changed to
include a normalized frequency value percentage normalized to whatever is the
maximum frequency value within that data table.

As a subsequent example, in Fig. 11 the user is trying to enter the word
"APOLOGIZE". The user has entered the key sequence "AS" "OP" "OP" "L" "OP".
Since "APPLOADER" has now been added as a word object 108 to the new words
database 92 and has been associated with frequency object 104 having a relatively high
frequency value, the prefix object "APPLO" which corresponds with "APPLOADER"
has been displayed as the default portion 76 of the output 64 in favor of the variant prefix
object "APLO", which corresponds with the desired word "APOLOGIZE." Since the
word "APOLOGIZE" corresponds with a word object 108 that is stored at least in the
generic word list 88, the user can simply continue to enter keystrokes corresponding with
the additional letters "GIZE", which would be the letters in the word "APOLOGIZE"
following the prefix object "APLO", in order to obtain the word "APOLOGIZE".
Alternatively, the user may, upon seeing the output 64 depicted in Fig. 11, enter a
selection input to affirmatively select the variant prefix object "APLO". In such a
circumstance, the learning function will be triggered upon detection of a delimiter
symbol, and the word object 108 that had corresponded with the linguistic element string
"APLO" at the time the selection input was made will be stored in the frequency
learning database 92 and will be associated with a revised frequency object 104 having a
relatively higher frequency value that is similarly stored in the frequency learning
database 92.

An additional feature of the handheld electronic device 4 is depicted generally in
Fig. 12. In some circumstances, it is desirable that the disambiguation function be
disabled. For instance, when it is desired to enter a password, disambiguation typically is
relatively more cumbersome than during ordinary text entry. As such, when the system
focus is on the component corresponding with the password field, the component
indicates to the API that special processing is requested, and the API disables the
disambiguation function and instead enables, for instance, a multi-tap input interpretation
system. Alternatively, other input interpretation systems could include a chording system
or a press-and-hold / press-and-release interpretation system. As such, while an input entered with the disambiguation function active is an ambiguous input, by enabling the alternative interpretation system, such as the exemplary multi-tap system, each input can be largely unambiguous.

As can be understood from Fig. 12, each unambiguous input is displayed for a very short period of time within the password field 120, and is then replaced with another output, such as the asterisk. The linguistic element "R" is shown displayed, it being understood that such display is only for a very short period of time.

As can be seen in Figs. 1 and 7-11, the output 64 includes the displayed graphic 46 near the lower end of the variant component 72, and that the displayed graphic 46 is highly similar to the graphic 42 of the <NEXT> key 40. Such a depiction provides an indication to the user which of the keys 28 of the keypad 24 can be actuated to select a variant output. The depiction of the displayed graphic 46 provides an association between the output 64 and the <NEXT> key 40 in the user's mind. Additionally, if the user employs the <NEXT> key 40 to provide a selection input, the user will be able to actuate the <NEXT> key 40 without moving the user's hands away from the position the hands were in with respect to the housing 6 during text entry, which reduces unnecessary hand motions, such as would be required if a user needed to move a hand to actuate the thumbwheel 32. This saves time and effort.

It is also noted that the system can detect the existence of certain predefined symbols as being delimiter signals if no word object 108 corresponds with the text entry that includes the symbol. For instance, if the user desired to enter the input "one-off", the user might begin by entering the key sequence "OP" "BN" "ER" "ZX" "OP", with the "ZX" actuation being intended to refer to the hyphen symbol disposed thereon. Alternatively, instead of typing the "ZX" key the user might actuate an <ALT> entry to unambiguously indicate the hyphen.

Assuming that the memory 20 does not already include a word object 108 of "one-off", the disambiguation function will detect the hyphen as being a delimiter input. As such, the key entries preceding the delimiter input will be delimited from the key entries subsequent to the delimiter input. As such, the desired input will be searched as two separate words, i.e., "ONE" and "OFF", with the hyphen therebetween. This facilitates processing by more narrowly identifying what is desired to be searched.
Another type of editing feature is depicted generally in Figs. 13-17. During text entry, if a user determines that the wrong word is being entered or output, the user may decide to delete certain of the terminal letters and to reenter the text. For instance, and as is depicted generally in Fig. 13, the user has entered the keystrokes “BN” “ER” “UI” “BN” “GH”. For example, the user has sought to enter the word “BRING”. The device 4 has, however, provided as a default component 768A the word “BEING”. It is clear to the user that the second keystroke, i.e., the “ER” keystroke, was not an incorrect keystroke, but rather the device simply provided an output other than what was desired by the user. In such a circumstance, the user may enter a deletion input, i.e., a number of actuations of the <DEL> key with respect to the terminal portion of the default component 768A, i.e., the terminal letters G, N, I, and E. The initial portion of what had been the default component 768A, i.e., the letter B depicted with the numeral 768B in Fig. 14, has not been deleted because it is what the user desired. It is noted that while a variant component 772A, 772B, and 772C have been depicted schematically in Figs. 13-15, the specific contents of such variant components 772A, 772B, and 772C has been left out of Figs. 13-15 for purposes of simplicity.

If the user at this point reenters the “ER” key, as is depicted generally in Fig. 15, the initial portion of what had been the default output 768A, i.e., the letter B, becomes “locked”. Moreover, the portion of the default component 768C that results from the actuation of the “ER” key is an opposite character of what had previously been output in the default component 768A. The letter E had been the output adjacent the initial portion of the default component 768A, but a reactivation of the “ER” key results in the default output now being the letter R.

If the user continues reactivating the same keys sequentially adjacent the letter that had been the subject of the character flip mentioned in the previous paragraph, that is, the E being flipped in favor of the R, the flipped character, i.e., R, also becomes locked. However, the portion of the default component 768D that resulted from reactivation of the “UI” key is not locked at this point, as can be seen in Fig. 16. Rather, the device provides a variant output 772D that includes the variants that correspond with the locked letters B and R, plus the various letters assigned to the “UI” key. In the example shown, the device has provided as a default portion 776D the character string BRI, and has provided as a variant portion 780D the character string BRU.
If at this point the "BN" key is reactuated, as is depicted generally in Fig. 17, the locked letters B and R remain locked, and the device 4 provides a variant component 772E that includes the locked letters B and R plus the various letters assigned to the "Ul" key and to the "BN" key. In the depicted exemplary circumstance, the default portion 776E, and thus the default component 768E, is the letter string BRIN. Three variants are provided as the variant portion 780E.

It is noted that if any of the keys actuated after deletion of the terminal portion of the default component 768A is a key other than what had originally been entered to provide the terminal portion, all letters in the word being typed become unlocked. It thus can be seen that if the user notices a word is being output incorrectly, the device 4 provides a way in which the error can be corrected. For example, if the user deletes terminal characters to the point that the erroneous output began to occur, i.e., the output of the letter E instead of the desired letter I, the letter can be flipped if the same key is reactuated. If subsequent keys are similarly reactuated, the flipped letter becomes locked, and variants are provided for the subsequent keys since the device 4 cannot be certain that the other letters in the terminal portion of the default component 768A were what the user desired. The user thus is given the opportunity to choose a variant after the character flip. On the other hand, if the user simply entered an incorrect key, upon actuation of the new key all letters are unlocked and the disambiguation routine operates on the input as if it is a new input without any locked letters.

An enhanced letter case entry feature is depicted in an exemplary fashion in Figs. 18-21. The memory 20 is capable of storing word objects with specific upper case and lower case letter makeups. For instance, the device 4 may have stored therein the words "blackberry", which refers to a fruit, and the word "BlackBerry", which is a proper noun having two capital letters. The case makeup, i.e., the makeup of upper and lower case elements, of these two words can be said to be different. However, the device advantageously provides capitalization in some circumstances to obviate the need for the user to always enter, for example, a shift key to obtain each capital letter desired in the output.

In an exemplary circumstance where the words "blackberry" and "BlackBerry", for instance, are both stored on the device 4, the user can obtain desired results with relatively reduced effort. For instance, and as is depicted generally in Fig. 18, the user has entered the keys "BN" "L" "AS" "CV" "JK" and "BN", and only one of the "BN"
entries was entered as upper case. In the present example, it was the second “BN” entry that was upper case. The device 4 compares the case makeup of the input with the case makeup of the identified word objects in the memory 20. Since the case makeup of what the user has enters includes at least one upper case “BN”, and since the case makeup of at least a portion of the word “BlackBerry” matches at least a portion of the case makeup of the input, i.e., an upper case “B”, the entire default component 868A and default portion 876A match the case makeup of the word “BlackBerry”. That is, even though the user entered only one upper case “BN”, the device 4 has proposed as a preferred variant the letter string BlackB with two capital letters since it is automatically providing capitalization in accordance with what the device 4 believes to be the wishes of the user. In the example presented in Fig. 18, the lower case character string “blackb” is output as a variant portion 880A of the variant component 872A, although this extra output can be eliminated without departing from the concept of the invention.

In the example depicted generally in Fig. 19, the user has entered the same character string, but all lower case. Since no upper case entry was made by the user, and thus the device 4 has not been apprised of any interest the user may have in obtaining a capitalized output, the default portion 876B of the variant component 872B, and thus also the default component 868B, is the lower case character string “blackb” as a preferred variant. However, the upper case letter string BlackB is also provided as a variant portion 880B to enable to user to obtain capitalization of, say, two letters, with only a single selection input with respect to the variant portion 880B, if desired by the user.

Another example is presented in Figs. 20 and 21. If a word object is stored in the memory 20 with a case makeup having one or more case elements that are upper case, and no corresponding lower case word object is stored in the memory 20, an input of all lower case actuations that corresponds with the upper case word will result in an output of the upper case word in accordance with the case makeup thereof. For instance, the user may have decided to input the male name “Todd”. In Fig. 20, the user has already actuated the keys “TY” “OP” and “DF” in lower case. Since the user has not provided any upper case input, the default portion 867C and the default component 868C are in lower case in the present example, such as the character string “tod”, which might correspond with the word “today” which is stored in the memory in a fashion having a case makeup consisting of lower case letters. The character string “Tod” having a case
makeup that includes a case element that is upper case is provided as part of a variant portion 880C of a variant component 872C.

However, if the user provides another lower case input of the “DF” key, the only word object in the memory 20 which corresponds with the input is the word “Todd”, which has a case makeup that includes a case element that is upper case. Since the word “Todd” was, in the present example, the only word element that corresponded with the input, the default portion 876D of the variant component 872D, as well as the default component 868D, is provided in accordance with the case makeup of the word object “Todd” despite the entry of all lower case input. The device 4 thus advantageously provides automated capitalization in certain circumstances.

An enhanced word frequency learning feature is depicted generally in Figs. 22-23. In the circumstance where a user is entering a given input sequence that corresponds with more than one word, such as in the way the input sequence “AS” “ER” “ER” can correspond with the words “are” and “see”, a user entering this sequence followed by a delimiter input will receive as output whichever of the two words “are” and “see” is associated with the word object having the highest frequency value despite the intentions of the user. In the example depicted in Fig. 22, the user has entered this input sequence, and the default component 968A, as well as the default portion 976A of the variant component 972A, is the word “are”. If the user “forces” the word “see” by entering a selection input as to the variant portion 980A “see”, as is depicted generally in Fig. 23 with respect to the variant component 972B thereof, the default portion 968B becomes “see”. In such a circumstance, if the user enters a delimiter input, the device 4 outputs the word “see”.

At this point, however, no frequency values have been adjusted on the device 4. If the user “forces” a lower frequency word twice in a row, however, the frequency values will be altered on the device 4 to reflect the user’s needs. That is, if the user a second time enters the input sequence “AS” “ER” “ER” and selects the word “see” in favor of the default word “are”, without in the meantime having entered the same sequence and accepted the default “are”, the word object “see” will be associated with a new frequency object having a relatively higher frequency value than the frequency value of the frequency object with which the word object “are” is associated.

Thereafter, if the user enters the input sequence “AS” “ER” “ER”, the default component will be “see” due to the altered frequency value. If, however, the user twice
in a row forces the word “are” upon entering this key sequence, without an intervening event of accepting the default “see”, the word object “are” will have its frequency value adjusted so that it will return to being the default word object.

While specific embodiments of the invention have been described in detail, it will be appreciated by those skilled in the art that various modifications and alternatives to those details could be developed in light of the overall teachings of the disclosure. Accordingly, the particular arrangements disclosed are meant to be illustrative only and not limiting as to the scope of the invention which is to be given the full breadth of the claims appended and any and all equivalents thereof.
CLAIMS:

1. A method of disambiguating an input into a handheld electronic device, the handheld electronic device including an input apparatus, an output apparatus, and a processor apparatus including a memory having a plurality of objects stored therein, the plurality of objects including a plurality of language objects, each language object of at least a portion of the plurality of language objects comprising at least a first linguistic element, the input apparatus including a plurality of input members, each of at least a portion of the input members of the plurality of input members having a plurality of linguistic elements assigned thereto, the method comprising:

   detecting an ambiguous input including a number of input member actuations of a number of the input members of the plurality of input members, each of at least a portion of the input members of the number of input members including a number of linguistic elements assigned thereto, at least one of the input members of the number of input members having a plurality of linguistic elements assigned thereto;

   generating a number of prefix objects corresponding with the ambiguous input, each prefix object of the number of prefix objects including a number of the linguistic elements of the number of the input members of the ambiguous input;

   for at least a first prefix object of the number of prefix objects, identifying at least a pair of language objects of the plurality of language objects corresponding with the at least a first prefix object, at least a portion of a first language object of the at least a pair of language objects having a first case makeup comprising a number of case elements, at least a portion of a second language object of the at least a pair of language objects having a second case makeup comprising a number of case elements, the first case makeup and the second case makeup being different than one another;

   outputting the at least a first prefix object in accordance with the first case makeup; and

   outputting the at least a first prefix object in accordance with the second case makeup.

2. The method of Claim 1, further comprising outputting as a variant the at least a first prefix object in accordance with the first case makeup, and outputting as another variant the at least a first prefix object in accordance with the second case makeup.
3. The method of Claim 1 wherein the ambiguous input has an input case makeup comprising a number of case elements, and further comprising determining that at least a portion of the input case makeup corresponds with at least a portion of one of the first case makeup and the second case makeup, outputting as a relatively more preferred variant the at least a first prefix object in accordance with the one of the first case makeup and the second case makeup, and outputting as a relatively less preferred variant the at least a first prefix object in accordance with the other of the first case makeup and the second case makeup.

4. The method of Claim 3, further comprising determining that the at least a portion of the input case makeup includes a case element that is upper case.

5. The method of Claim 4, further comprising determining that another portion of the input case makeup includes a case element that is lower case, and determining that a corresponding case element of the one of the first case makeup and the second case makeup is a case element that is upper case.

6. A method of disambiguating an input into a handheld electronic device, the handheld electronic device including an input apparatus, an output apparatus, and a processor apparatus including a memory having a plurality of objects stored therein, the plurality of objects including a plurality of language objects, each language object of at least a portion of the plurality of language objects comprising at least a first linguistic element, the input apparatus including a plurality of input members, each of at least a portion of the input members of the plurality of input members having a plurality of linguistic elements assigned thereto, the method comprising:

   detecting an ambiguous input including a number of input member actuations of a number of the input members of the plurality of input members, each of at least a portion of the input members of the number of input members including a number of linguistic elements assigned thereto, at least one of the input members of the number of input members having a plurality of linguistic elements assigned thereto, the ambiguous input having an input case makeup comprising a number of case elements;
generating a number of prefix objects corresponding with the ambiguous input, each prefix object of the number of prefix objects including a number of the linguistic elements of the number of the input members of the ambiguous input;

for at least a first prefix object of the number of prefix objects, identifying at least a pair of language objects of the plurality of language objects corresponding with the at least a first prefix object, at least a portion of a first language object of the at least a pair of language objects having a first case makeup comprising a number of case elements, at least a portion of a second language object of the at least a pair of language objects having a second case makeup comprising a number of case elements, the first case makeup and the second case makeup being different than one another;

determining that at least a portion of the input case makeup including a case element that is upper case corresponds with at least a portion of one of the first case makeup and the second case makeup; and

outputting the at least a first prefix object in accordance with the one of the first case makeup and the second case makeup.

7. The method of Claim 6, further comprising determining that another portion of the input case makeup includes a case element that is lower case, and determining that a corresponding case element of the one of the first case makeup and the second case makeup is a case element that is upper case.

8. A method of disambiguating an input into a handheld electronic device, the handheld electronic device including an input apparatus, an output apparatus, and a processor apparatus including a memory having a plurality of objects stored therein, the plurality of objects including a plurality of language objects, each language object of at least a portion of the plurality of language objects comprising at least a first linguistic element, the input apparatus including a plurality of input members, each of at least a portion of the input members of the plurality of input members having a plurality of linguistic elements assigned thereto, the method comprising:

detecting an ambiguous input including a number of input member actuations of a number of the input members of the plurality of input members, each of at least a portion of the input members of the number of input members including a number of linguistic
elements assigned thereto, at least one of the input members of the number of input members having a plurality of linguistic elements assigned thereto;

    generating a number of prefix objects corresponding with the ambiguous input, each prefix object of the number of prefix objects including a number of the linguistic elements of the number of the input members of the ambiguous input, the ambiguous input having an input case makeup comprising a number of case elements;

    for a prefix object of the number of prefix objects, identifying a language object of the plurality of language objects that corresponds therewith, at least a portion of the identified language object having a stored case makeup comprising a number of case elements, at least a portion of the input case makeup and at least a portion of the stored case makeup being different than one another;

    outputting as a variant the prefix object in accordance with the stored case makeup.

9. The method of Claim 6, further comprising outputting as a preferred variant the prefix object in accordance with the stored case makeup.
AMENDED CLAIMS
received by the International Bureau on 18 September 2006 (18.09.2006)
+ STATEMENT

1. A method of disambiguating a character input into a handheld electronic device, the handheld electronic device including an input apparatus for inputting characters into the device, an output apparatus for outputting characters, and a processor apparatus for electronically processing characters, including a memory having a plurality of objects stored therein, the plurality of objects including a plurality of language objects, i.e., any type of object that may be constructed, identified or otherwise interpreted from one or more linguistic characters to generate text, each of at least a portion of the language objects comprising a first linguistic character, the input apparatus including a plurality of input members, at least a portion of the input members having a plurality of linguistic characters assigned thereto, the method comprising:

detecting an ambiguous input including a number of input member actuations of a number of the input members, each of at least a portion of the input members including a number of linguistic characters assigned thereto, at least one of the input members having a plurality of linguistic characters assigned thereto, wherein the ambiguous input has an input case makeup, i.e., having a sequence of linguistic characters in upper and/or lower case;

generating a number of prefix objects comprising various permutations of the characters corresponding with the ambiguous input, each prefix object including a number of the linguistic characters of the number of the input members of the ambiguous input;

for at least a first prefix object, identifying at least a pair of language objects corresponding with the first prefix object, at least a portion of a first language object of the pair of language objects having a first case makeup, i.e., having a sequence of linguistic characters in upper and/or lower case, at least a portion of a second language object of the pair of language objects having a second case makeup, the first case makeup and the second case makeup being different than one another;

determining that at least a portion of the input case makeup corresponds with at least a portion of one of the first case makeup and the second case makeup;

outputting as a relatively more preferred variant, i.e., a predetermined quantity of alternative proposed interpretations of the same ambiguous input, the first prefix object in accordance with the one of the first case makeup and the second case makeup; and
outputting as a relatively less preferred variant the first prefix object in accordance with the other of the first case makeup and the second case makeup.

2. The method of Claim 1, further comprising determining that the portion of the input case makeup includes a linguistic character that is upper case and the linguistic character in the input case makeup that is upper case corresponds to the same upper case linguistic character in the one of the first case makeup and the second case makeup to output as the relatively more preferred variant the one of the first case makeup and the second case makeup.

3. The method of Claim 2, further comprising determining that another portion of the input case makeup includes a linguistic character that is lower case, and determining that a corresponding linguistic character of the one of the first case makeup and the second case makeup is a linguistic character that is upper case.

4. The method of Claim 1 including the steps of:
   associating at least a portion of the number of prefix objects respectively with a corresponding word object having a frequency object with a corresponding frequency value stored in the memory; and
   outputting the portion of the number of prefix objects in a list in descending order of frequency value except that the preferred variant is listed ahead of the relatively less preferred variant.
STATEMENT UNDER ARTICLE 19(1) PCT

Newly submitted claims 1 to 4 replace original claims 1 to 9 in the application. Original claims 1, 4 and 5 have been amended and a new claim has been added. Claims 2, 3, and 6 to 9 have been cancelled. The remaining claims have been renumbered. Original claims 2 and 3 have been incorporated into claim 1 and claim 1 has been further modified in a more concise and clear form. Original claim 4 has been renumbered as claim 2 and its dependency changed to claim 1. Claim 4 has been similarly amended. Claim 5 has been renumbered as claim 3 and its dependency changed to claim 2. The other changes to claim 5 were made to enhance clarity. The newly added claim is now numbered as claim 4. The amendments to the claims should not impact the description or the drawings.
FIG. 2

FIG. 2a
DETECT INPUT

RESET TIMER

IS INPUT AN OPERATIONAL INPUT?

ADD INPUT TO CURRENT INPUT SEQUENCE

GENERATE PREFIX OBJECTS FOR CURRENT INPUT SEQUENCE

IS INPUT FIELD SPECIAL?

FOR EACH PREFIX OBJECT, IDENTIFY IN MEMORY THE HIGHEST FREQUENCY LANGUAGE OBJECT(S), IF ANY, THAT CORRESPONDS WITH THE PREFIX OBJECT, TO GENERATE A RESULT

DETERMINE NEED FOR ARTIFICIAL VARIANTS

FILTER FROM THE RESULT DUPLICATE WORD OBJECTS WITH RELATIVELY LOWER FREQUENCY

ARRANGE PREFIX OBJECTS IN RESULT IN DECREASING ORDER OF FREQUENCY TO GENERATE AN OUTPUT SET

IS FLAG SET?

ALTER CONTENTS AND/OR ORDER OF OUTPUT SET

FIG. 3a
FROM MAIN PROCESS

DOES RESULT INCLUDE ANY PREFIX OBJECT THAT CORRESPONDS WITH PREVIOUS DEFAULT OUTPUT?

Y

WAS SELECTION FLAG SET?

N

RETURN TO MAIN PROCESS 232

312

DID PREVIOUS DEFAULT OUTPUT CORRESPOND WITH A WORD OBJECT?

N

Y

GENERATE ARTIFICIAL VARIANTS -- PREVIOUS DEFAULT OUTPUT PLUS EACH CHARACTER ASSIGNED TO CURRENT INPUT

GENERATE ARTIFICIAL VARIANTS -- PREFIX OBJECT WITH HIGHEST FREQUENCY EDITED TO REPLACE FINAL CHARACTER WITH AN OPPOSITE CHARACTER OF CURRENT INPUT

314

316

320

324

FIG. 4
FROM MAIN PROCESS

DOES DEFAULT OUTPUT MATCH A WORD OBJECT IN MEMORY?

STORE DEFAULT OUTPUT IN NEW WORDS DATABASE AS A NEW WORD OBJECT; STORE IN NEW WORDS DATABASE AND ASSOCIATE WITH NEW WORD OBJECT A FREQUENCY OBJECT HAVING PREDETERMINED FREQUENCY VALUE

OBTAIN MOST RECENTLY STORED WORD OBJECTS FROM TEMPORARY LEARNING DATA REGISTER

HAVE THIS DEFAULT WORD OBJECT AND VARIANT WORD OBJECT PREVIOUSLY BEEN THE SUBJECT OF FREQUENCY LEARNING FUNCTION?

STORE VARIANT WORD OBJECT IN FREQUENCY LEARNING DATABASE; STORE IN FREQUENCY LEARNING DATABASE A FREQUENCY OBJECT HAVING RELATIVELY HIGHER FREQUENCY VALUE THAN VARIANT FREQUENCY OBJECT AND ASSOCIATE WITH STORED VARIANT WORD OBJECT

FIG. 5a
FIG. 5b

RETURN TO MAIN PROCESS

420

STORE VARIANT WORD OBJECT IN FREQUENCY LEARNING DATABASE. STORE IN FREQUENCY LEARNING DATABASE A FREQUENCY OBJECT HAVING A RELATIVELY HIGHER FREQUENCY VALUE THAN DEFAULT FREQUENCY OBJECT, AND ASSOCIATE WITH STORED VARIANT WORD OBJECT.
FROM MAIN PROCESS

FOR EACH PREFIX OBJECT, IDENTIFY IN THE SPECIAL DATA SOURCE THE HIGHEST FREQUENCY LANGUAGE OBJECT(S), IF ANY, THAT CORRESPONDS WITH THE PREFIX OBJECT TO GENERATE A SPECIALIZED RESULT

FILTER DUPLICATE RESULTS

IS QUANTITY OF REMAINING RESULTS LESS THAN A PREDETERMINED NUMBER?

RETURN TO MAIN PROCESS AT 236

ARRANGE PREFIX RESULTS IN DECREASING ORDER OF FREQUENCY TO GENERATE A SPECIAL OUTPUT SET

SET SPECIAL FLAG TO APPEND CONVENTIONAL RESULTS FROM OTHER DATA SOURCES TO END OF SPECIAL OUTPUT SET

RETURN TO MAIN PROCESS AT 224

FIG. 6A
INTERNATIONAL SEARCH REPORT

A. CLASSIFICATION OF SUBJECT MATTER
   IPC: G06F 3/01 (2006.01), G06F 17/27 (2006.01), G06F 15/18 (2006.01), G06F 15/02 (2006.01)
   According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED
   Minimum documentation searched (classification system followed by classification symbols)
   IPC: all
   Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched
   Electronic database(s) consulted during the international search (name of database(s) and, where practicable, search terms used)
   Delphion, IEEE Xplore, Google Scholar, Google & keywords: disambiguate, upper/lower case, text/letter case, case makeup, capitalization map/pattern, medial capitals, CamelCase; bicapitalized; intercaps; internal/non-standard/irregular/mixed/automated capitalization; mixed case; word mixing: autocorrect; spellcheck.

C. DOCUMENTS CONSIDERED TO BE RELEVANT

[X] Further documents are listed in the continuation of Box C. [X] See patent family annex.

* Special categories of cited documents:
   "A" document defining the general state of the art which is not considered to be of particular relevance
   "E" earlier application or patent but published on or after the international filing date
   "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
   "O" document referring to an oral disclosure, use, exhibition or other means
   "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"A" document member of the same patent family

Date of the actual completion of the international search: 5 June 2006 (05-06-2006)
Date of mailing of the international search report: 20 July 2006 (20-07-2006)
