(54) Title: LIQUID FUEL CPOX REFORMERS AND METHODS OF CPOX REFORMING

FIG. 4P

(57) Abstract: A liquid fuel catalytic partial oxidation (CPOX) reformer can include a plurality or an array of spaced-apart CPOX reactor units, each reactor unit including an elongate tube having a gas-permeable wall with internal and external surfaces, the wall enclosing an open gaseous flow passageway with at least a portion of the wall having CPOX catalyst disposed therein and/or comprising its structure. The catalyst-containing wall structure and open gaseous flow passageway enclosed thereby define a gaseous phase CPOX reaction zone, the catalyst-containing wall section being gas-permeable to allow gaseous CPOX reaction mixture to diffuse therein and hydrogen rich product reformat to diffuse therefrom. At least the exterior surface of the CPOX reaction zone can include a hydrogen barrier. The liquid fuel CPOX reformer can include a vaporizer, one or more igniters, and a source of liquid reformable fuel.

## **LIQUID FUEL CPOX REFORMERS AND METHODS OF CPOX REFORMING**

### **CROSS REFERENCE TO RELATED APPLICATIONS**

**[0001]** This application claims priority to and the benefit of the filing date of U.S. Provisional Patent Application No. 61/900,510, filed on November 6, 2013, the entire disclosure of which is incorporated by reference herein.

### **FIELD**

**[0002]** The present teachings relate to liquid fuel catalytic partial oxidation reformers and methods of catalytic partial oxidation reforming of liquid reformable fuels to produce hydrogen-rich reformates.

### **BACKGROUND**

**[0003]** The conversion of a gaseous or liquid reformable fuel to a hydrogen-rich carbon monoxide-containing gas mixture, a product commonly referred to as “synthesis gas” or “syngas,” can be carried out in accordance with any of such well known fuel reforming operations such as steam reforming, dry reforming, autothermal reforming, and catalytic partial oxidation (CPOX) reforming. Each of these fuel reforming operations has its distinctive chemistry and requirements and each is marked by its advantages and disadvantages relative to the others.

**[0004]** The development of improved fuel reformers, fuel reformer components, and reforming processes continues to be the focus of considerable research due to the potential of fuel cells, i.e., devices for the electrochemical conversion of electrochemically oxidizable fuels such hydrogen, mixtures of hydrogen and carbon monoxide, and the like, to electricity, to play a greatly expanded role for general applications including main power units (MPUs) and auxiliary power units (APUs). Fuel cells also can be used for specialized applications, for example, as on-board electrical generating devices for electric vehicles, backup power sources for residential-use devices, main power sources for leisure-use, outdoor and other power-consuming devices in out-of-grid locations, and lighter weight, higher power density, ambient temperature-independent replacements for portable battery packs.

**[0005]** Because large scale, economic production of hydrogen, infrastructure required for its distribution, and practical means for its storage (especially as a transportation fuel) widely are believed to be a long way off, much current research and development has been directed to improving both fuel reformers as sources of electrochemically oxidizable fuels, notably mixtures of hydrogen and carbon monoxide, and fuel cell assemblies, commonly referred to as fuel cell “stacks,” as converters of such fuels to electricity, and the integration of fuel reformers and fuel cells into more compact, reliable and efficient devices for the production of electrical energy.

**[0006]** CPOX reforming, or simply CPOX, has attracted particular attention as a way of supplying hydrogen-rich reformat to fuel cell stacks, for example, those having nominal power ratings of anywhere from 100 watts to 100 kilowatts, and all power ratings in between. Among the advantages of CPOX reforming is that the reaction is exothermic in contrast to steam reforming and dry reforming which are endothermic reactions that require an external source of heat.

**[0007]** Furthermore, CPOX reactions are generally faster than other reforming reactions which allows for the construction of relatively small reformers capable of fast start-up and rapid response to changes in load. CPOX reformers also tend to be simpler in design than reformers that require the handling of water and steam, for example, steam reformers and autothermal reformers, which require storage units for water, heating units for the production of steam, burner or combustion units for supplying heat to drive endothermic reforming reactions, and the like, and their associated fluid routing and operation-monitoring and control devices.

**[0008]** However, and as previously recognized (see, e.g., U.S. Patent Nos. 6,790,431 and 7,578,861), the typically high levels of heat produced during CPOX reactions can have undesirable consequences including damage to the reformer and/or components thereof such as the CPOX catalyst, catalyst support, and other structural components. This is a major drawback of many current CPOX reformer designs and one in need of an effective solution.

[0009] One known type of CPOX reformer includes a catalyst support component, commonly referred to as a “catalyst monolith,” “monolith catalyst support,” “monolith substrate,” or simply a “monolith,” which has a CPOX catalyst or catalyst system deposited thereon.

[0010] Monoliths can be classified on the basis of two general configurations: a first configuration characterized by a metal or ceramic body of honeycomb-like, channeled, metallic gauze or spiral-wound corrugated sheet structure presenting an essentially linear gaseous flow path therethrough, and a second configuration characterized by a metal or ceramic foam body of reticulated, or open, pore structure presenting a tortuous gaseous flow path therethrough. Representative monoliths of one or the other general type are disclosed in, for example, U.S. Patent Nos. 5,527,631; 6,402,989; 6,458,334; 6,692,707; 6,770,106; 6,887,456; 6,984,371; 7,090,826; 7,118,717; 7,232,352; 7,909,826; 7,976,787; 8,323,365; and, U.S. Patent Application Publication No. 2013/0028815.

[0011] As shown in FIG. 1A, monolith 100, which is of a common prior art type, viewed in longitudinal cross section includes a honeycomb-like ceramic body 101 made up of numerous channels 102 impregnated or wash-coated with CPOX catalyst, an inlet end 103 for admitting a gaseous CPOX reaction mixture, i.e., a mixture of a gaseous oxidizing agent, typically air, and reformable fuel, e.g., a gaseous fuel such as methane, natural gas, propane or butane or a vaporized liquid fuel such as gasoline, kerosene, jet fuel or diesel, an outlet end 104 for the discharge of hydrogen-rich, carbon monoxide-containing reformat product (syngas) and a CPOX reaction zone 105 which is essentially coextensive with the entire monolith.

[0012] CPOX reaction zone 105 can be considered as having an inner, or central, region 106 through which a corresponding inner, or central, portion of a gaseous CPOX reaction mixture stream inherently flows within a relatively high range of velocity  $V_1$  surrounded by an outer, or peripheral, region 107 through which a corresponding outer, or peripheral, portion of the gaseous CPOX reaction mixture stream inherently flows within a relatively low range of velocity  $V_2$ .

[0013] Monoliths typically experience fairly high CPOX reaction temperatures, for example, on the order of from 600 °C to 1,100 °C. In the case of honeycomb-like monolith 100, these high temperatures, coupled with the inherent differential in flow velocities  $V_1$  and  $V_2$  of the CPOX reaction mixture stream flowing within inner and outer regions 106 and 107, respectively, of CPOX reaction zone 105 tend to account for the observed operational drawbacks of monolith 100 and other essentially linear flow path monoliths where CPOX reforming is concerned.

[0014] At CPOX reaction temperatures of 600 °C - 1,100 °C, monolith 100 radiates a good deal of heat at its inlet end 103. Even with careful monitoring and control of the CPOX reaction conditions, it can be difficult to prevent or inhibit the phenomenon of “flashing,” i.e., the premature combustion of CPOX gaseous reaction mixture stream within radiant heat zone 108 as the stream approaches inlet end 103. Heat of exotherm of the CPOX reaction occurring within initial CPOX reaction zone 109 proximate to inlet end 103 radiates outwardly therefrom into radiant heat zone 108. This radiant heat can be of sufficient intensity to raise the temperature of the advancing CPOX reaction mixture stream (indicated by the arrows) to its flash point. Flashing of the CPOX reaction mixture within radiant heat zone 108 causes undesirable thermal events, raising the temperature to a point where catalyst can be vaporized or deactivated and/or reformer structure can be damaged or rendered inoperative. These thermal events can also lead to cracking of fuel within this zone and, consequently, increased coke (carbon particle) formation resulting in deterioration of CPOX catalyst performance. Where the hydrogen-rich reformat effluent is utilized as fuel for a fuel cell stack, coke and unreformed higher hydrocarbon fragments contained therein will also deposit upon the anode surfaces of the fuel cells resulting in reduced conversion of product reformat to electricity.

[0015] As further shown in FIG. 1A, the aforementioned differential in flow velocities  $V_1$  and  $V_2$  of the CPOX reaction mixture stream within, respectively, inner and outer regions 106 and 107 of CPOX reaction zone 105 are also primarily responsible for the differential in CPOX reaction temperature ranges  $T_1$  and  $T_2$  in these regions. Thus, the higher velocity  $V_1$  of the CPOX reaction mixture stream

within inner region **106** results in a higher rate of CPOX reaction therein and an accompanying higher reaction temperature  $T_1$  and, conversely, the lower velocity  $V_2$  of the CPOX reaction mixture stream within outer region **107** results in a lower rate of CPOX reaction therein and an accompanying lower reaction temperature  $T_2$ . The temperature profile across inner and outer regions **106** and **107** can be represented by temperature curve **110**. A sharp rise in CPOX reaction temperature  $T_1$ , if high enough, can result in damage to, and even total destruction of, monolith **100**.

[0016] As shown in **FIG. 1B**, prior art-type foam monolith **150** viewed in longitudinal cross section includes a ceramic foam body **151** characterized by a reticulated, or open, network of interconnected pores and pore channels **152** supporting a CPOX catalyst or catalyst system deposited thereon by conventional or otherwise known procedures, e.g., impregnation or wash coating.

[0017] One drawback of foam monoliths of all types is their higher pressure drops due to their higher resistance to flow compared with linear-flow monoliths such as honeycomb-like monolith **100** of **FIG. 1A**. Higher pressure drops require higher operational pressures, and therefore higher energy consumption, to meet target flows. Another inherent drawback of foam monoliths lies in the nature of the flow paths of gaseous reactants and reaction products therein (as indicated by the arrows). The characteristic randomness of these flow paths results in very uneven temperature profiles within the monolith (e.g., as indicated by temperature curve **153**), increasing the risk of thermal shock due to hot spots and/or reduced CPOX conversion rates due to cold spots.

[0018] Foam monoliths of all types are also susceptible to flashing much as in the case of the linear flow path monoliths discussed above. In addition, foam monoliths are prone to other drawbacks that are characteristic of their kind. Depending on the way in which known and conventional foam monoliths are manufactured, they can possess a relatively fragile pore network, especially within their central regions, or they can possess a more robust pore structure throughout. Both types of foam monolith are subject to disadvantages.

[0019] In the case of foam monoliths possessing a relatively fragile core region, thermal shock resulting from rapid thermal cycling of the CPOX reformer (typical of CPOX reformers that supply hydrogen-rich reformat to fuel cell assemblies) can over time degrade their structures to the point where the CPOX reaction proceeds in a very inefficient manner, if at all.

[0020] In the case of foam monoliths possessing a sturdier pore structure, such structure tends to magnify the randomness of the gas flow paths therethrough. While damage to the pore structure owing to hot spots can be negligible or nonexistent, the problem of scattered and fleeting cold spots that negatively affect the productivity of the CPOX reaction remains a drawback of this type of foam monolith.

[0021] It will also be noted that even when manufactured by a well-defined, closely-controlled process, foam monoliths will differ in their pore structures, and therefore in their gaseous flow properties, from other foam monoliths produced by the same process. As a result of unavoidable differences in their microstructures, individual foam monoliths produced by the same process of manufacture tend to exhibit idiosyncratic operational characteristics that can only be determined empirically. As a practical matter, a broader range of performance and reliability parameters or specifications will be assigned to reformers incorporating foam monoliths of the same manufacture in order to make allowance for the unpredictable variations in their performance.

[0022] Accordingly, the industry desires new designs of CPOX reformers and new methods of CPOX reforming that can address certain of the disadvantages of the prior art.

### SUMMARY

[0023] In light of the foregoing, the present teachings provide liquid fuel CPOX reformers and methods of CPOX reforming of liquid fuels that can address one or more of the deficiencies and/or disadvantages of the state-of-the-art, for example, little or no opportunity or tendency for flashing to occur, no excessively high CPOX reaction temperatures, and/or low back pressures throughout all of its gaseous stream-routing and gaseous flow components and passageways.

**[0024]** In one aspect, the present teachings relate to a liquid fuel CPOX reformer including an array of spaced-apart CPOX reactor units; a vaporizer in fluid communication with inlets of the CPOX reactor units; and an igniter in thermal communication with a CPOX catalyst of at least one CPOX reactor unit of the liquid fuel CPOX reformer, for example, a CPOX catalyst-containing wall section of at least one CPOX reactor unit. A CPOX reactor unit typically includes an elongate tube having a wall with an internal surface and an external surface. As such, a “liquid fuel CPOX reformer” can be considered a “liquid fuel multi-tubular CPOX reformer,” with such expressions and permutations thereof being used interchangeably herein unless otherwise understood from the context. The wall of the CPOX reactor unit encloses an open gaseous flow passageway and defines an inlet at one end for receiving fluid flow and an outlet at an opposing end for discharge of fluid flow. A CPOX reactor unit can be in thermal communication with at least the adjacent CPOX reactor unit(s) in the array. The CPOX reactor unit can have at least a section of its wall, including the internal surface, include a CPOX catalyst. The CPOX catalyst-containing wall section typically is gas-permeable to allow gaseous CPOX reaction mixture to diffuse therein and hydrogen-rich product reformat to diffuse therefrom while remaining structurally stable under CPOX reaction conditions.

**[0025]** The liquid fuel CPOX reformer can include a hydrogen barrier associated with, for example, attached or adhered to, the external surface of at least the CPOX catalyst-containing wall section. The hydrogen barrier also can be associated with a majority, substantially all, or the entire external surface of the wall of a CPOX reactor unit. In addition, the hydrogen barrier can be associated with the entire exposed external surface of the wall of a CPOX reactor unit. For example, a pressurized fluid such as a pressurized gas can be a hydrogen barrier, for example, associated with at least the external surfaces of the CPOX catalyst-containing wall section.

**[0026]** With respect to the array of spaced-apart CPOX reactor units and their thermal communication, the CPOX reactor units are generally spaced apart at a distance close enough for the heat from a CPOX reaction in one CPOX reactor unit to initiate a CPOX reaction in one or more adjacent CPOX reactor units. However, the CPOX reactor units are generally spaced apart at a distance far enough to permit

control of the temperature of the CPOX reactor units, particularly at the outlets of the CPOX reactor units. That is, the CPOX reactor units are spaced apart so that heat loss can occur from a CPOX reactor unit to prevent damage to the CPOX reactor unit and if present, to a fuel cell stack that can be in fluid and thermal communication with the outlet(s) of the CPOX reactor unit(s). With such positioning, an array of spaced-apart CPOX reactor units can provide an appropriate thermal balance among the array and can facilitate thermal uniformity throughout or across the array.

**[0027]** For example, the maximum distance between adjacent CPOX reactor units can be that distance beyond which a CPOX reaction fails to be initiated in an adjacent CPOX reactor unit by the heat from a CPOX reaction in a CPOX reactor unit. In other words, initiating a CPOX reaction in one (a single) CPOX reactor unit of an array can create the necessary heat to initiate a CPOX reaction in each of the CPOX reactor units of the array of CPOX reactor units. The maximum distance can be that distance beyond which, during a steady-state mode of operation, the temperature of an array of CPOX reactor units falls below a predetermined minimum array temperature, for example, about 600 °C or about 650 °C.

**[0028]** The minimum distance between adjacent CPOX reactor units can be that distance below which the temperature at an outlet of a CPOX reactor unit is greater than a predetermined maximum temperature. The predetermined maximum temperature can be a temperature that is tolerable by an inlet of a fuel cell stack in thermal and fluid communication with an outlet of a CPOX reactor unit, for example, about 875 °C or 900 °C.

**[0029]** The liquid fuel CPOX reformer can include a source of liquid reformable fuel in fluid communication with the vaporizer. The liquid fuel CPOX reformer can include a single igniter, or can include more than one igniter, for example, two igniters, three igniters or more, where additional igniters can be positioned in thermal communication with CPOX catalyst-containing wall sections of other CPOX reactor units.

**[0030]** The CPOX catalyst-containing wall section can include a ceramic or can be a ceramic. The CPOX catalyst-containing wall section can be a porous substrate,

for example, a porous substrate including a ceramic or a porous ceramic. At least the section of the wall including a CPOX catalyst can be or can include a perovskite. For example, greater than about 20% or greater than about 50% by weight of such wall section can be a perovskite. A CPOX catalyst can be disposed within the wall and/or disposed on an internal surface of the wall. For example, a CPOX catalyst or CPOX catalyst system can be deposited on a wall and/or surface such as the internal surface of a wall, for example, by impregnation, wash coating, or an equivalent procedure. A CPOX catalyst also partially or completely can form the wall, i.e., the structure of the wall. In certain embodiments, the amount of CPOX catalyst within a catalyst-containing wall section of a CPOX reactor unit can increase along the length of the wall section, for example, in the direction from the inlet to the outlet end of the CPOX reactor unit, and/or can decrease from the inner surface to the outer surface of the wall. Such gradients of CPOX catalysts, if present, typically are in the CPOX reaction zone of a CPOX reactor unit.

[0031] Another feature of the present teachings includes an oxygen-containing gas conduit comprising a branch conduit that can split or divide the oxygen-containing gas from a source of oxygen-containing gas such that a primary fluid stream of oxygen-containing gas can be mixed with a vaporized liquid reformable fuel in, downstream of or coincident with the vaporizer, for example, where the vaporizer is a fuel spreader such as a sprayer or a wick, and a secondary fluid stream of oxygen-containing gas can be mixed with the resulting gaseous CPOX reaction mixture downstream of or coincident with the vaporizer. In such a way, the oxygen (O) to carbon (C) ratio ("O:C ratio") can be kept lower upstream of and/or through the vaporizer (or zone of vaporization) to mitigate against or prevent ignition of the reaction mixture as well as flashback. That is, the secondary stream of oxygen-containing gas can be added to the CPOX reaction mixture downstream of the vaporizer and upstream of the inlets to the CPOX reactor units to provide a CPOX reaction mixture having a higher O:C ratio for CPOX reaction in the CPOX reactor units.

[0032] The use of a conduit as described above having a branch conduit that can split or divide the flow of oxygen-containing gas can assist in the thermal

management of the CPOX reformer and its associated components. The reduced volumetric flow of fluids through the vaporizer, for example, about 50% less, can require less heat to be supplied to the vaporizer for it to reach its operating temperature as there is less oxygen-containing gas to heat. During start-up and shut-down modes of operation, the volumes of the primary fluid and secondary fluid streams can be adjusted as appropriate.

[0033] Accordingly, a liquid fuel CPOX reformer can include a source of oxygen-containing gas, where the source of oxygen-containing gas is in fluid communication with the vaporizer and in fluid communication with a mixing zone downstream of the vaporizer. The liquid fuel CPOX reformer can include an oxygen-containing gas conduit including a branch conduit, where the oxygen-containing gas conduit can provide fluid communication between a source of oxygen-containing gas and the vaporizer and the branch conduit can provide fluid communication between the source of oxygen-containing gas and a mixing zone downstream of the vaporizer. The oxygen-containing gas conduit having a branch conduit can divide the delivery of an oxygen-containing gas from the source of oxygen-containing gas to the vaporizer and the mixing zone downstream of the vaporizer. In such cases, the CPOX reaction mixture formed in the vaporizer or coincident with and/or downstream of the vaporizer (e.g., where the vaporizer is located in the conduit and can be a fuel spreader) can have an O:C ratio that is less than the CPOX reaction mixture to be delivered to the inlets of the CPOX reactor units.

[0034] In a variation on this basic theme, rather than having a conduit including a branch conduit split the flow of oxygen-containing gas, the liquid fuel CPOX reformer can include a first source of oxygen-containing gas in fluid communication with the vaporizer and a second source of oxygen-containing gas in fluid communication with a mixing zone downstream of the vaporizer. In this configuration, two separate conduits, one for each source of oxygen-containing gas, can be used, where the independent conduits can merge in a mixing zone downstream of the vaporizer. The use of two different sources of oxygen-containing gas can achieve the same variations in the O:C ratio as described above or elsewhere herein.

**[0035]** Another feature of the present teachings includes a conduit comprising an oxygen-containing gas inlet and a gaseous CPOX reaction mixture outlet located downstream from an outlet of a vaporizer. The conduit can provide fluid communication between the oxygen-containing gas inlet and the gaseous CPOX reaction mixture outlet. The conduit can provide fluid communication among the oxygen-containing gas inlet, an outlet of the vaporizer and the gaseous CPOX reaction mixture outlet. The gaseous CPOX reaction mixture outlet can be in fluid communication with the inlets of the CPOX reactor units. A first source of heat, which can include a heater such as an electric heater, can be disposed in the conduit at a location downstream from the oxygen-containing gas inlet and upstream from the outlet of the vaporizer. A second source of heat, which can include heat of exotherm from the liquid fuel CPOX reformer and/or a hydrogen reformat-consuming device external to the liquid fuel reformer, can be in thermal communication with the conduit and at a location downstream from the first source of heat and upstream from or coincident with the outlet of the vaporizer. The outlet of the vaporizer can be in fluid communication with the conduit. For example, the outlet of the vaporizer can be in fluid communication with the conduit via another conduit or can be directly adjacent a port in the conduit. The vaporizer can be disposed in the conduit. The vaporizer can be or include a fuel spreader such as a sprayer or a wick.

**[0036]** In various embodiments, a third source of heat, which can include a heater such as an electric heater, can be disposed in the conduit at a location downstream from the first source of heat and upstream from the outlet of the vaporizer. In some embodiments, a liquid fuel CPOX reformer can include a thermally-regulating assembly, the thermally-regulating assembly including a heater and a cooler. The thermally-regulating assembly can be disposed in and/or can be in thermal communication with the conduit at a location downstream from the first source of heat and upstream from the outlet of the vaporizer.

**[0037]** Yet another feature of the presenting teachings is a manifold for distributing gaseous CPOX reaction mixture to the inlets of the CPOX reactor units, i.e., the manifold (or the manifold chamber) can be in fluid communication with the inlets of the CPOX reactor units. The manifold includes a manifold housing, where

the manifold housing defines a manifold chamber. The manifold can include a gaseous CPOX reaction mixture distributor disposed within, and extending for at least a majority of the length of, the manifold chamber. The gaseous CPOX reaction mixture distributor can be in fluid communication with a conduit that outputs a gaseous CPOX reaction mixture. The gaseous CPOX reaction mixture distributor can include one or more outlets located opposite the inlets of the CPOX reactor units. The manifold can include a heater and/or passive heating elements in thermal communication with the manifold chamber. The manifold can include a cavity, where the manifold housing defines the cavity. A seal can be disposed within or adjacent to the cavity. The manifold housing typically includes a plurality of cavities, wherein the number and arrangement of the cavities coincide with the number and arrangement of the inlets of the CPOX reactor units. The seal can engage the inlet of the CPOX reactor unit thereby providing a gas-tight seal between the manifold housing and the inlet.

**[0038]** In another aspect, the present teachings provide a method of liquid fuel CPOX reforming. Methods of the present teachings generally include introducing a gaseous CPOX reaction mixture including a vaporized liquid reformable fuel into inlets of CPOX reactor units of liquid fuel CPOX reformers of the present teachings; initiating catalytic partial oxidation of the gaseous CPOX reaction mixture to begin production of a hydrogen-rich reformat; and maintaining catalytic partial oxidation of the gaseous CPOX reaction mixture.

**[0039]** In various embodiments, introducing a gaseous CPOX reaction mixture includes introducing a gaseous CPOX reaction mixture including a vaporized liquid reformable fuel into inlets of CPOX reactor units, where the CPOX reactor units form an array of spaced-apart CPOX reactor units, each CPOX reactor unit comprising an elongate tube having a wall with an internal surface and an external surface, the wall enclosing an open gaseous flow passageway and defining an inlet and an outlet of the CPOX reactor unit. The CPOX reactor unit can be in thermal communication with at least the adjacent CPOX reactor unit(s) in the array. At least a section of the wall can include a CPOX catalyst. The CPOX catalyst-containing wall section can be gas-permeable to allow gaseous CPOX reaction mixture to diffuse therein and product

(hydrogen-rich) reformat to diffuse therefrom. The CPOX catalyst-containing wall section can remain structurally stable under CPOX reaction conditions. The distance between adjacent CPOX reactor units in the array can be as described herein.

**[0040]** Initiating catalytic partial oxidation can include initiating a single igniter to begin the CPOX reaction within a CPOX reactor unit, which in turn can initiate the CPOX reaction in the other CPOX reactor units of the liquid fuel CPOX reformer. For example, initiating catalytic partial oxidation can include initiating a CPOX reaction in one CPOX reactor unit; transferring the heat from the CPOX reaction to an adjacent CPOX reactor unit to initiate a CPOX reaction therein; and repeating transferring the heat to initiate a CPOX reaction in each of the CPOX reactors of the array.

**[0041]** Initiating catalytic partial oxidation also can include initiating more than a single igniter, for example, two, three, four, five or more igniters, to begin the CPOX reaction(s) within the CPOX reactor units of the liquid fuel CPOX reformer.

**[0042]** In various embodiments, maintaining catalytic partial oxidation of the gaseous CPOX reaction mixture includes transferring heat among the CPOX reactor units within the array thereby to use less external heating than otherwise would be required for the same output of hydrogen-rich reformat. The heat transfer among the array of CPOX reactor units can maintain a predetermined minimum array temperature, for example, about 600 °C or 650 °C. The predetermined minimum array temperature can be substantially uniform across the array of CPOX reactor units.

**[0043]** In certain embodiments, methods of liquid fuel CPOX reforming can include using the heat of exotherm of the ongoing CPOX reaction(s) and/or heat from some other source to heat the oxygen-containing gas component and/or heat and/or vaporize the liquid reformable fuel of the gaseous CPOX reaction mixture about to undergo CPOX reforming.

**[0044]** In some embodiments, methods of liquid fuel CPOX reforming can include vaporizing a liquid reformable fuel. Vaporizing a liquid reformable fuel can be done at ambient temperature or an elevated temperature, for example, upon contact

with heated oxygen-containing gas. The methods can include mixing an oxygen-containing gas and a vaporized liquid reformable fuel to provide a gaseous CPOX reaction mixture. Mixing an oxygen-containing gas and a vaporized liquid reformable fuel can provide a gaseous CPOX reaction mixture having an oxygen (O):carbon (C) ratio. The methods can include mixing additional oxygen-containing gas with the initially-formed gaseous CPOX reaction mixture to increase the O:C ratio of the gaseous CPOX reaction mixture upstream of or prior to introducing the gaseous CPOX reaction mixture having an increased O:C ratio into the inlets of the CPOX reactor units.

[0045] Where a fluid stream of oxygen-containing gas is split upstream of or prior to a vaporizer, or is reduced in volume through the vaporizer (e.g., where two sources of oxygen-containing gas are used such as with two independent conduits), the methods can include mixing an oxygen-containing gas and a vaporized liquid reformable fuel upstream of, coincident with, through or in a vaporizer, where the amount of heat required to heat the vaporizer to its operating temperature is less than the amount of heat required in the absence of the step of mixing additional oxygen-containing gas with the gaseous CPOX reaction mixture where the method provides a gaseous CPOX reaction mixture having the increased O:C ratio to the inlets of the CPOX reactor units.

[0046] In certain embodiments, methods of liquid fuel CPOX reforming can include distributing a gaseous CPOX reaction mixture including a vaporized liquid reformable fuel of substantially uniform composition, at a substantially uniform rate, and/or at a substantially uniform temperature to the inlets of one or more of several CPOX reactor units.

[0047] In various embodiments of the present teachings, introducing a gaseous CPOX reaction mixture into an inlet of a CPOX reactor unit can include introducing an oxygen-containing gas into a conduit for routing fluids toward the inlet of a CPOX reformer unit; heating a stream of the oxygen-containing gas with a first source of heat including an electric heater disposed in the conduit to provide a stream of heated oxygen-containing gas; and introducing a liquid reformable fuel into the stream of

heated oxygen-containing gas in, through, coincident with, or past (downstream from) a vaporizer to provide the gaseous CPOX reaction mixture.

**[0048]** The methods can include heating the stream of the oxygen-containing gas and/or the stream of heated oxygen-containing gas with a second source of heat, the second source of heat in thermal communication with the conduit and including heat of exotherm from the CPOX reactor units and/or a hydrogen reformat-consumng device external to the CPOX reactor units. The methods can include heating and/or cooling upstream of the vaporizer the stream of oxygen-containing gas and/or the stream of heated oxygen-containing gas, for example, to regulate the temperature of the stream of oxygen-containing gas and/or the stream of heated oxygen-containing gas. Heating a stream of heated oxygen-containing gas can be with a third source of heat including an electric heater disposed in the conduit downstream from the first source of heat.

**[0049]** The methods can include discontinuing heating the stream of oxygen-containing gas with the first source of heat; and reducing or discontinuing heating the stream of oxygen-containing gas and/or the stream of heated oxygen-containing gas with the third source of heat.

**[0050]** Further, in accordance with the present teachings, methods are provided for CPOX reforming of a liquid reformable fuel in a start-up mode and in a steady-state mode to produce a hydrogen-rich reformat, where the methods generally include:

a) in a start-up mode:

(i) introducing a heated gaseous CPOX reaction mixture comprising oxygen-containing gas and vaporized liquid reformable fuel into the inlet of each of a plurality of spaced-apart CPOX reactor units, each reactor unit comprising an elongate tube having a wall with internal and external surfaces, the wall enclosing an open gaseous flow passageway with at least a section of the wall having CPOX catalyst disposed therein, comprising its structure or combinations thereof, such catalyst-containing wall section and open gaseous flow passageway enclosed thereby defining a gaseous phase

CPOX reaction zone, the catalyst-containing wall section being gas-permeable to allow gaseous CPOX reaction mixture to diffuse therein and product reformat to diffuse therefrom while remaining stable under CPOX reaction conditions,

(ii) initiating CPOX reforming of the heated gaseous CPOX reaction mixture within the CPOX reaction zones of the CPOX reactor units thereby commencing the production of hydrogen-rich reformat; and,

b) in a steady-state mode:

(iii) introducing a heated gaseous CPOX reaction mixture into the inlets of the CPOX reactor units,

(iv) discontinuing CPOX initiating step (ii) prior to, during or following step (iii), and

(v) maintaining the CPOX reaction within the CPOX reaction zones of the CPOX reactor units thereby continuing the production of gaseous hydrogen-rich reformat.

**[0051]** In various embodiments, the methods described herein can include, for example, in step (i) recited above, adjusting the molar ratio of oxygen to carbon of the gaseous CPOX reaction mixture to correspond to that of a fuel-lean CPOX reaction mixture. In particular embodiments, the methods can include, for example, in step (iii) recited above, adjusting the molar ratio of oxygen to carbon of the gaseous CPOX reaction mixture to correspond to that of a fuel-rich CPOX reaction mixture.

**[0052]** In some embodiments, the methods can include flowing fluids such as a gas using a blower or a blower system, for example, a series of blower units. Each blower unit in the series can include a casing having an axial inlet and radial outlet, an impeller disposed within the casing for drawing an oxygen-containing gas at a first pressure in the inlet and expelling oxygen-containing gas at a higher pressure through the outlet, a motor for driving the impeller, and a duct containing the outlet of at least one blower unit in the series in the inlet of at least one other blower unit in the series. In certain embodiments, at least one blower unit in the series of blower units can provide from 60 % to 90 % of the target gas flow of the blower system. In such

embodiments, at least one other blower unit in the series of blower units can provide the balance of target gas flow of the blower system.

[0053] The foregoing as well as other features and advantages of the present teachings will be more fully understood from the following figures, description, detailed exemplary embodiments, and claims.

#### **BRIEF DESCRIPTION OF THE DRAWINGS**

[0054] It should be understood that the drawings described below are for illustration purposes only. The drawings are not necessarily to scale, with emphasis generally being placed upon illustrating the principles of the present teachings. The drawings are not intended to limit the scope of the present teachings in any way. Like numerals generally refer to like parts.

[0055] **FIGS. 1A and 1B** are longitudinal cross section views of two prior art types of catalyst monoliths, specifically, a honeycomb-like catalyst monolith and a foam catalyst monolith, respectively.

[0056] **FIGS. 2A and 2B** are schematic block diagrams of two embodiments of a liquid fuel CPOX reformer in accordance with the present teachings.

[0057] **FIG. 3A** is a schematic block diagram of an exemplary control system for managing the operations of the liquid fuel CPOX reformers of **FIGS. 2A and 2B**.

[0058] **FIG. 3B** is a flowchart of an exemplary control routine executed by a controller such as the control system illustrated in **FIG. 3A**.

[0059] **FIG. 4A** is a longitudinal cross section view of an embodiment of a liquid CPOX reformer in accordance with the present teachings.

[0060] **FIG. 4B** is a lateral (perpendicular to the longitudinal axis) cross section view of the liquid fuel CPOX reformer illustrated in **FIG. 4A**.

[0061] **FIG. 4C** is a plan cross section view of a portion of the liquid fuel CPOX reformer illustrated in **FIG. 4A**.

[0062] **FIG. 4D** is an enlarged longitudinal cross section view of the liquid fuel vaporizer system of the liquid fuel CPOX reformer illustrated in **FIG. 4A**.

[0063] **FIGS. 4E and 4F** are, respectively, enlarged perspective and longitudinal cross section views of an embodiment of a fuel spreader component of a liquid fuel vaporizer system of the liquid fuel CPOX reformer illustrated in **FIGS. 4A and 4D**.

[0064] **FIG. 4G** is an enlarged longitudinal cross section view of another embodiment of a liquid fuel vaporizer system for a liquid fuel CPOX reformer in accordance with the present teachings.

[0065] **FIG. 4H** is an enlarged perspective view of the igniter component of the liquid fuel CPOX reformer illustrated in **FIGS. 4A-4C**.

[0066] **FIG. 4I** is an enlarged longitudinal cross section view of a portion of the manifold and associated tubular CPOX reactor units of the liquid fuel CPOX reformer illustrated in **FIGS. 4A-4C**.

[0067] **FIGS. 4J and 4K** are enlarged longitudinal and lateral cross section views, respectively, of one of the tubular CPOX reactor units shown in **FIG. 4I**.

[0068] **FIGS. 4L and 4M** are lateral cross section views of two other embodiments of tubular CPOX reactor units of liquid fuel CPOX reformers of the present teachings.

[0069] **FIGS. 4N and 4O** illustrate, respectively, perspective and plan views of the blower system components of the liquid fuel CPOX reformers illustrated in **FIGS. 4A, 5A, 5B, 6A and 6B**.

[0070] **FIG. 4P** is a longitudinal cross section view of another embodiment of a liquid CPOX reformer in accordance with the present teachings similar to **FIG. 4A**.

[0071] **FIGS. 5A and 5B** are longitudinal cross section views of additional embodiments of liquid fuel CPOX reformers in accordance with the present teachings featuring external heating of oxygen-containing gas and/or liquid reformable fuel during the steady-state mode of operation of the reformers.

[0072] **FIGS. 6A and 6B** are longitudinal cross section views of embodiments of heat exchanger structures for controlling the temperature within the CPOX reaction zones of the CPOX reactor units of the liquid fuel CPOX reformers illustrated in **FIGS. 5A and 5B**.

[0073] FIG. 6C is a plan cross section view of an embodiment of heat exchanger structures for controlling the temperature within the CPOX reaction zones of the CPOX reactor units of the liquid fuel CPOX reformers illustrated in FIGS. 5A and 5B.

[0074] FIG. 7 presents graphical data showing the relationship between the molar ratio of oxygen to carbon of the CPOX reaction mixture on the CPOX reaction temperature within a liquid fuel CPOX reformer of the present teachings at varying percentages of maximum fuel (diesel) conversion capacity when the reformer is operating in the steady-state mode.

#### DETAILED DESCRIPTION

[0075] It now has been discovered that an array of spaced-apart CPOX reactor units can take advantage of the exothermic CPOX reaction to provide a more efficient reforming process. Unlike known and conventional CPOX reformers which employ catalyst monoliths that are susceptible to flashing, the formation of localized hot spots and cold spots, rapid coke-buildup, and/or excessively high-spiking CPOX reaction temperatures, an array of spaced-apart CPOX reactor units of the present teachings can mitigate or eliminate one or more of these drawbacks.

[0076] For example, the distribution of the total CPOX reforming or CPOX conversion load among an array of spaced-apart CPOX reactor units can simplify and facilitate the maintenance of effective thermal balance and control of the overall CPOX reforming. Such a design can permit more vaporized liquid reformable fuel to be processed for a given CPOX catalyst loading by lowering operating temperatures for a given energy input.

[0077] The improved thermal management of the liquid fuel CPOX reformers as described herein also can contribute to the stabilization of the temperature of the CPOX reaction taking place within each of the CPOX reactor units. Consequently, such improved thermal management can maintain suitably uniform CPOX conversion performance among the CPOX reactor units of a liquid fuel CPOX reformer.

[0078] In addition, the design of the CPOX reformers of the present teachings can take advantage of the exothermic CPOX reaction and can permit an array of spaced-

apart CPOX reactor units to be ignited with a minimum number of igniters, for example, a single igniter, whereby the initiation of the CPOX reaction in one of the CPOX reactor units can provide sufficient heat to adjacent CPOX reactor unit(s) to begin the CPOX reforming therein and eventually in each of the CPOX reactor units of the liquid fuel CPOX reformer. Although a single igniter can be advantageous in a liquid fuel CPOX reformer, the present teachings contemplate the use of more than a single or one igniter in the liquid fuel CPOX reformer as the specific size of the array and CPOX reactor units, placement of the CPOX reactor units and igniters, and other factors can contribute to an overall efficient initiation or start-up process for CPOX reforming. Nevertheless, an advantage of distributing the total CPOX conversion load among a plurality of CPOX reactor units in contrast to a single CPOX reactor of comparable fuel conversion capacity is the shorter start-up time.

[0079] Moreover, the spaced-apart arrangement of the plurality of CPOX reactor units can simplify the design and manufacture of a related series or line of liquid fuel CPOX reformers, where individual liquid fuel CPOX reformers can differ in their fuel-reforming capacities. For example, a new, liquid fuel CPOX reformer design that desires increased fuel-reforming capacity readily can be constructed by adding additional liquid fuel CPOX reactor units of standardized specification to an existing design with a few, if any, other significant modifications.

[0080] It is to be understood that the present teachings herein are not limited to the particular procedures, materials, and modifications described and as such can vary. It is also to be understood that the terminology used is for purposes of describing particular embodiments only and is not intended to limit the scope of the present teachings, which will be limited only by the appended claims.

[0081] Throughout the application, where compositions are described as having, including, or comprising specific components, or where processes are described as having, including, or comprising specific process steps, it is contemplated that compositions of the present teachings also consist essentially of, or consist of, the recited components, and that the processes of the present teachings also consist essentially of, or consist of, the recited process steps.

**[0082]** In the application, where an element or component is said to be included in and/or selected from a list of recited elements or components, it should be understood that the element or component can be any one of the recited elements or components, or the element or component can be selected from a group consisting of two or more of the recited elements or components. Further, it should be understood that elements and/or features of a composition, an apparatus, or a method described herein can be combined in a variety of ways without departing from the focus and scope of the present teachings, whether explicit or implicit herein. For example, where reference is made to a particular structure, that structure can be used in various embodiments of apparatus of the present teachings and/or in methods of the present teachings.

**[0083]** The use of the terms “include,” “includes,” “including,” “have,” “has,” “having,” “contain,” “contains,” or “containing,” including grammatical equivalents thereof, should be generally understood as open-ended and non-limiting, for example, not excluding additional unrecited elements or steps, unless otherwise specifically stated or understood from the context.

**[0084]** The use of the singular herein, for example, “a,” “an,” and “the,” includes the plural (and vice versa) unless specifically stated otherwise.

**[0085]** Where the use of the term “about” is before a quantitative value, the present teachings also include the specific quantitative value itself, unless specifically stated otherwise. As used herein, the term “about” refers to a  $\pm 10\%$  variation from the nominal value unless otherwise indicated or inferred.

**[0086]** It should be understood that the order of steps or order for performing certain actions is immaterial so long as the present teachings remain operable. For example, the methods described herein can be performed in any suitable order unless otherwise indicated herein or otherwise clearly contradicted by context. Moreover, two or more steps or actions can be conducted simultaneously.

**[0087]** At various places in the present specification, values are disclosed in groups or in ranges. It is specifically intended that the description include each and every individual subcombination of the members of such groups and ranges and any

combination of the various endpoints of such groups or ranges. For example, an integer in the range of 0 to 40 specifically is intended to individually disclose 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, and 40, and an integer in the range of 1 to 20 specifically is intended to individually disclose 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, and 20.

**[0088]** The use of any and all examples, or exemplary language provided herein, for example, “such as,” is intended merely to better illuminate the present teachings and does not pose a limitation on the scope of the invention unless claimed. No language in the specification should be construed as indicating any non-claimed element as essential to the practice of the present teachings.

**[0089]** Terms and expressions indicating spatial orientation or altitude such as “upper,” “lower,” “top,” “bottom,” “horizontal,” “vertical,” and the like, unless their contextual usage indicates otherwise, are to be understood herein as having no structural, functional or operational significance and as merely reflecting the arbitrarily chosen orientation of the various views of liquid fuel CPOX reformers of the present teachings illustrated in certain of the accompanying figures.

**[0090]** The term “ceramic,” in addition to its art-recognized meaning, shall be understood herein to include glasses, glass-ceramics, and cermets (i.e., ceramic-metal composites).

**[0091]** The expression “gas permeable,” as it applies to a wall of a CPOX reactor unit herein, shall be understood to mean a wall structure that is permeable to gaseous CPOX reaction mixtures and gaseous product reformat including, without limitation, the vaporized liquid reformable fuel component of the gaseous CPOX reaction mixture and the hydrogen component of the product reformat.

**[0092]** The expression “liquid reformable fuel” shall be understood to include reformable carbon- and hydrogen-containing fuels that are a liquid at standard temperature and pressure (STP) conditions, for example, methanol, ethanol, naphtha, distillate, gasoline, kerosene, jet fuel, diesel, biodiesel, and the like, that when subjected to reforming undergo conversion to hydrogen-rich reformates. The

expression “liquid reformable fuel” shall be further understood to include such fuels whether they are in the liquid state or in the gaseous state, i.e., a vapor.

**[0093]** The expression “gaseous reformable fuel” shall be understood to include reformable carbon- and hydrogen-containing fuels that are a gas at STP conditions, for example, methane, ethane, propane, butane, isobutane, ethylene, propylene, butylene, isobutylene, dimethyl ether, their mixtures, such as natural gas and liquefied natural gas (LNG), which are mainly methane, and petroleum gas and liquefied petroleum gas (LPG), which are mainly propane or butane but include all mixtures made up primarily of propane and butane, and the like, that when subjected to reforming undergo conversion to hydrogen-rich reformates. A gaseous reformable fuel also includes ammonia, which like other gaseous reformable fuels, can be stored as a liquid.

**[0094]** The expression “CPOX reaction” shall be understood to include the reaction(s) that occur during catalytic partial oxidation reforming or conversion of a reformable fuel to a hydrogen-rich reformate.

**[0095]** The expression “gaseous CPOX reaction mixture” refers to a mixture including a gaseous liquid reformable fuel (e.g., a vaporized liquid reformable fuel), a gaseous reformable fuel, or combinations thereof, and an oxygen-containing gas, for example, air. As used herein, a gaseous CPOX reaction mixture includes a vaporized liquid reformable fuel (or a gaseous liquid reformable fuel).

**[0096]** The expression “open gaseous flow passageway” refers to a conduit or channel for the passage of gas therethrough where a solid, including a porous solid or material, is not present across the entire cross-sectional plane of the conduit or channel, i.e., a conduit or channel free of solids, including porous solids. For example, in the case of a CPOX reactor unit, CPOX catalyst including a porous catalyst such as a monolith cannot be present across the entire internal cross-sectional plane perpendicular to the longitudinal axis of a tubular CPOX reactor unit. Such a structure is distinct from passageways which are packed with a porous catalyst, for example, a monolith, as previously discussed. An open gaseous flow passageway also can be present in a CPOX reactor unit which can be defined as a tube which

defines a hollow bore, or a cylindrical substrate defining a hollow bore therethrough along its longitudinal axis. In these exemplary descriptions, the hollow bore can be considered an open gaseous flow passageway. Although an open gaseous flow passageway usually can extend along a longitudinal axis of a CPOX reactor unit, a tortuous conduit or channel also is contemplated by the present teachings and can be capable of having an open gaseous flow passageway provided that the tortuous conduit or channel is free of solids across a cross-sectional plane of the CPOX reactor unit. It also should be understood that the cross-sectional dimension(s) of an open gaseous flow passageway can vary long its longitudinal axis or along the tortuous conduit or channel.

[0097] An important feature of a liquid fuel CPOX reformer of the present teachings is the array of spaced-apart CPOX reactor units. An array of CPOX reactor units can refer to an orderly arrangement or a regular placement of a CPOX reactor unit in relation to the other CPOX reactor unit(s). In other words, the CPOX reactor units typically are not randomly positioned or placed. Although straight line, square, and rectangular configurations are commonly used, other configurations such as hexagonal and octagonal are contemplated by the present teachings.

[0098] The arrangement or placement of the CPOX reactor units, for example, distance and location with respect to adjacent CPOX reactor units, can be determined by various factors including, among others, the positioning and configuration of the plurality of CPOX reactor units, the materials of construction of the CPOX reactor units such as its walls and CPOX catalyst, the liquid reformable fuel, the operating temperature of the CPOX reactor units, the desired use and output of product hydrogen-rich reformat, for example, the materials of construction of a hydrogen reformat-consuming device such as a fuel cell unit or system to which the CPOX reformer is to be connected or coupled. If the distance between or among (adjacent) CPOX reactor units is too great, then the CPOX reactors units will not be thermally connected or have insufficient thermal communication, for example, to initiate a CPOX reaction in an adjacent CPOX reactor unit and/or to maintain a heat transfer zone roughly encompassing the plurality of CPOX reactor units. Conversely, if the distance between or among (adjacent) CPOX reactor units is too small, the CPOX

reactor units may be subjected to overheating and degradation, which can result in malfunction of the liquid fuel CPOX reformer.

**[0099]** More specifically, the maximum distance between adjacent CPOX reactor units can be that distance beyond which a CPOX reaction fails to be initiated within an adjacent CPOX reactor unit by the heat generated from an initial CPOX reaction (e.g., an initial CPOX reaction initiated by an igniter) in a first-ignited CPOX reactor unit or from a CPOX reaction in an operating CPOX reactor unit. The maximum distance can be that distance beyond which, during a steady-state mode of operation, the temperature of the array of spaced-apart CPOX reactor units falls below a predetermined minimum array temperature. Depending on various factors, including those discussed herein, the predetermined minimum array temperature of an array of spaced-apart CPOX reactor units during steady-state mode of operation can be about 550 °C, about 575 °C, about 600 °C, about 625 °C, about 650 °C, about 675 °C, about 700 °C, about 725 °C, about 750 °C, about 775 °C, about 800 °C, about 825 °C, or about 850 °C.

**[0100]** The minimum distance between adjacent CPOX reactor units can be that distance below which the temperature at an outlet of a CPOX reactor unit is greater than a predetermined maximum temperature. The predetermined maximum temperature can be a temperature that is tolerable by an inlet of a fuel cell stack in thermal and fluid communication with an outlet of a CPOX reactor unit, for example, a temperature at which the seals of the inlets of the fuel cell stack do not degrade and remain functional. Depending on various factors, including those discussed herein, the predetermined maximum temperature of a CPOX reactor unit can be about 775 °C, about 800 °C, about 825 °C, about 850 °C, about 875 °C, about 900 °C, about 925 °C, about 950 °C, about 975 °C, or about 1000 °C.

**[0101]** Another feature of CPOX reformers of the present teachings is an igniter for initiating the CPOX reaction within the CPOX reactor units, for example, an array of CPOX reactor units. In various embodiments, a single igniter can be used to initiate a CPOX reaction within each of the CPOX reactor units of a liquid fuel CPOX reformer. In other embodiments, more than a single or one igniter, for

example, two igniters, three igniters, or more than three igniters can be used to initiate or start the CPOX reaction within the CPOX reactor units. The number and placement of the igniter(s) can be determined by various parameters including, for example, the design, structure and placement of the CPOX reactor units, and the desired efficiency and rapidity of start-up of a liquid fuel CPOX reformer.

**[0102]** An igniter can include a radiant heat-producing element positioned in proximity to, but in physical isolation from, an internal surface of a CPOX reactor unit, which also can be disposed within a chamber. For example, an igniter can transmit radiant heat to an exposed internal surface and/or CPOX catalyst of at least one CPOX reactor unit in proximity thereto to initiate the CPOX reaction therein. Subsequently, radiant heat produced by the CPOX reaction occurring within the CPOX reaction zone of the at least one CPOX reactor unit in turn can initiate a CPOX reaction within at least one other CPOX reactor unit, typically also within the chamber, until in such manner the CPOX reaction has been initiated in all of the CPOX reactor units of the liquid fuel CPOX reformer.

**[0103]** In various embodiments of a liquid fuel CPOX reformer of the present teachings, a vaporizer, for example, to vaporize liquid reformable fuel, can be in fluid communication with the inlets of the CPOX reactor units. The vaporizer should be operated to avoid heating the liquid reformable fuel to a temperature at or above its flash point as well as to avoid causing thermochemical degradation, for example, pyrolysis, of the reformable fuel. In certain embodiments, a vaporizer can be a fuel spreader such as a sprayer or a wick. A vaporizer can be located in a conduit such as the main conduit, which is in fluid communication with the inlets of the CPOX reactor units. A vaporizer can be located outside such a conduit (e.g., the main conduit), for example, adjacent to and/or in fluid communication with the (main) conduit via a port or other inlet in the main conduit and/or via another conduit providing fluid communication between the vaporizer and the main conduit.

**[0104]** In some embodiments, a hydrogen barrier can be associated with, such as attached to, the external surface of at least the catalyst-containing wall section of a tubular CPOX reactor unit, which catalyst-containing wall section typically defines

the CPOX reaction zone. The hydrogen barrier can be attached to the entire external surface of the wall of a CPOX reactor unit. The hydrogen barrier can prevent or inhibit the loss of hydrogen from the CPOX reactor unit. In the absence of such a barrier, hydrogen may diffuse through and beyond the catalyst-containing wall section of the CPOX reactor unit rather than exit the CPOX reactor unit through its outlet.

**[0105]** In particular embodiments, a liquid fuel CPOX reformer can include a source of liquid reformable fuel. The source of liquid reformable fuel can include a drum, barrel, tank or other container for storage and/or delivery of a liquid reformable fuel to the liquid fuel CPOX reformer, for example, to a vaporizer for converting the liquid reformable fuel into a vaporized or gaseous liquid reformable fuel.

**[0106]** Accordingly, in various embodiments, a liquid fuel CPOX reformer can include an array of spaced-apart CPOX reactor units; an igniter in thermal communication with a CPOX catalyst of at least one CPOX reactor unit; a vaporizer in fluid communication with inlets of the CPOX reactor units; and a source of liquid reformable fuel in fluid communication with the vaporizer. The CPOX reactor units can include an elongate tube, for example, a cylinder defining a hollow bore, having a gas-permeable ceramic wall with an internal surface and an external surface, where at least a section of the gas-permeable ceramic wall comprises a CPOX catalyst. The gas-permeable ceramic wall can enclose an open gaseous flow passageway and defines an inlet and an outlet of the CPOX reactor unit. When in an array, a CPOX reactor unit usually is in thermal communication with at least the adjacent CPOX reactor unit(s) in the array.

**[0107]** In some embodiments, a liquid fuel CPOX reformer can include a plurality of spaced-apart CPOX reactor units, each reactor unit comprising an elongate tube having an inlet for gaseous CPOX reaction mixture, and an outlet for hydrogen-rich reformate, a wall with internal and external surfaces, the wall enclosing an open gaseous flow passageway with at least a portion of the wall having CPOX catalyst disposed therein, comprising its structure or a combination thereof, such catalyst-containing wall section and open gaseous flow passageway enclosed thereby defining

a gaseous phase CPOX reaction zone, the catalyst-containing wall section being gas-permeable to allow gaseous CPOX reaction mixture to diffuse therein and product hydrogen-rich reformat to diffuse therefrom while remaining stable under CPOX reaction conditions.

**[0108]** In some embodiments, heat recovered from the exotherm of an ongoing CPOX reaction and/or heat recovered from one or more other heat sources can be utilized to heat oxygen-containing gas, heat liquid reformable fuel, and/or vaporize liquid reformable fuel prior to formation of a gaseous CPOX reaction mixture.

**[0109]** In certain embodiments of the present teachings, a conduit can be present and include an oxygen-containing gas inlet and a gaseous CPOX reaction mixture outlet located downstream from an outlet of a vaporizer. The conduit can provide fluid communication between the oxygen-containing gas inlet and the gaseous CPOX reaction mixture outlet. The conduit can provide fluid communication among the oxygen-containing gas inlet, an outlet of the vaporizer and the gaseous CPOX reaction mixture outlet. The gaseous CPOX reaction mixture outlet can be in fluid communication with the inlets of the CPOX reactor units. A first source of heat, which can include a heater such as an electric heater, can be disposed in the conduit at a location downstream from the oxygen-containing gas inlet and upstream from the outlet of the vaporizer. A second source of heat, which can include heat of exotherm from the liquid fuel CPOX reformer and/or a hydrogen reformat-consuming device external to the liquid fuel reformer, can be in thermal communication with the conduit and at a location downstream from the first source of heat and upstream from or coincident with the outlet of the vaporizer. The outlet of the vaporizer can be in fluid communication with the conduit. For example, the outlet of the vaporizer can be in fluid communication with the conduit via another conduit or can be directly adjacent a port in the conduit. The vaporizer can be disposed in the conduit. The vaporizer can be or include a fuel spreader such as a sprayer or a wick.

**[0110]** In various embodiments, a third source of heat, which can include a heater such as an electric heater, can be disposed in the conduit at a location downstream from the first source of heat and upstream from the outlet of the vaporizer. In some

embodiments, a liquid fuel CPOX reformer can include a thermally-regulating assembly, where the thermally-regulating assembly includes a heater and a cooler. The heater and/or the cooler can be independently disposed in and/or be in thermal communication with the conduit at a location downstream from the first source of heat and upstream from the outlet of the vaporizer. In certain embodiments, the thermally-regulating assembly can be substituted for the third source of heat.

[0111] In particular embodiments, a controller in operable communication with a thermocouple located in the conduit at or downstream from an outlet of the vaporizer, a thermocouple located in the conduit upstream of the vaporizer, an oxygen-containing gas flow meter located in the conduit upstream of the vaporizer, a liquid reformable fuel flow meter located at or upstream of the vaporizer and in fluid communication with a source of liquid reformable fuel, a source of oxygen-containing gas, a source of liquid reformable fuel, the first source of heat, the second source of heat, when present, and the third source of heat and/or the thermally-regulating assembly, when present.

[0112] In operation, one or more heaters such as electric heaters in a conduit can heat a stream of oxygen-containing gas, for example, introduced into the conduit, which can direct fluids toward the inlets of the CPOX reactor units. The heated oxygen-containing gas can assist in heating a liquid reformable fuel and/or maintain a gaseous state of the vaporized liquid reformable fuel (or at least not cool the liquid reformable fuel and/or vaporized liquid reformable fuel) when mixed to form a gaseous CPOX reaction mixture. As the CPOX reactor units start-up and begin to generate heat, the heat of exotherm of the CPOX reactions can be used to heat the oxygen-containing gas. Consequently, the use of the one or more electric heaters can be discontinued.

[0113] In certain cases, a heater and a cooler of a thermally-regulating assembly can be independently present in the conduit and/or in thermal communication with the conduit. The thermally-regulating assembly including a heater and a cooler can be positioned at a location downstream from the first source of heat and upstream from the liquid reformable fuel inlet, usually sufficiently upstream of the vaporizer to be

able to adjust the temperature of the stream of (heated) oxygen-containing gas and in particular, the stream of (heated) oxygen-containing gas heated by the exotherm of the CPOX reactions, before it reaches the vaporizer to prevent a thermal run away situation.

**[0114]** For example, the heater can be an electric heater such as an electrical resistance heater located in the conduit. The heater can be located exterior to the conduit but in thermal communication with it. The cooler can be a fluid (e.g., liquid) heat exchanger in thermal communication with the conduit, for example, the exterior surface of the conduit, such that cooling fluids at an appropriate temperature can be circulated through the fluid heat exchanger to lower the temperature of the stream of heated oxygen-containing gas (or in some cases where a CPOX reaction is conducted with gaseous reformable fuel upstream in the conduit, the stream of CPOX reaction mixture). That is, the thermally-regulating assembly can control and adjust the temperature of the stream of (heated) oxygen-containing gas (or CPOX reaction mixture) to raise or to lower its temperature, as appropriate for the operating system.

**[0115]** To assist in the thermal monitoring and regulation of the oxygen-containing gas, a controller such as a microprocessor can be used, where the controller monitors the flow rates of the liquid reformable fuel and/or the oxygen-containing gas and the temperatures of the vaporizer and the pre-heating sections (e.g., where the first, second and third sources of heat and/or thermally-regulating assembly can be located, when present) of the conduit(s) leading to the vaporizer. In such a fashion, the vaporization of the liquid reformable fuel and/or the creation of a gaseous CPOX reaction mixture can be controlled, for example, via a closed loop system including the controller and appropriate sensor and valve assemblies that are in operable communication as appropriate.

**[0116]** The electric heaters can be electrical resistance heaters. The vaporizer can include a liquid fuel line, where the liquid fuel line provides fluid communication between the vaporizer and a source of liquid fuel. The terminal section of the liquid fuel line located in the conduit can be a fuel spreader, for example, a sprayer or a wick. The liquid fuel line can include a heat transfer section. The heat transfer

section of the liquid fuel line can be in thermal communication with and in proximity to at least one of the first source of heat, the second source of heat, and the third source of heat or thermally-regulating assembly, when present.

[0117] In various embodiments, a liquid fuel CPOX reformer can be capable of alternately or concurrently processing gaseous reformable fuel to hydrogen-rich reformat. For example, a gaseous reformable fuel can be first used to initiate a CPOX reaction and heat up the other components of the system. The CPOX reaction can be in the CPOX reactor units. However, the CPOX reaction can be in the (main) conduit downstream from the inlet for the source of oxygen-containing gas and the inlet for the source of gaseous reformable fuel. For example, the conduit can include an inlet for gaseous reformable fuel, and a CPOX catalyst-containing section downstream from the gaseous reformable fuel inlet and the oxygen-containing gas inlet and upstream from the outlet of the vaporizer. In such a design and operation, a CPOX reaction early in the reformer system can facilitate a quick and efficient thermal start-up of the reformer and its various components.

[0118] In either case and possibly both, after the reformer has initiated CPOX reaction in the CPOX reactor units, the heat of exotherm from the CPOX reaction in the conduit and/or CPOX reactor units can be used to heat liquid reformable fuel and assist in vaporizing the liquid reformable fuel so that when in steady-state operation, only liquid reformable fuel can be used (i.e., the use of gaseous reformable fuel can be discontinued or reduced). The use of gaseous reformable fuel initially to start-up the CPOX reformer followed by the use of liquid reformable fuel in addition to or by itself can provide an efficient and quick start-up of the CPOX reformer compared to start-up with only liquid reformable fuel, which would require more heat input for the system to achieve its operational temperature because of the need to heat and vaporize the liquid reformable fuel.

[0119] In certain embodiments, a liquid fuel CPOX reformer can have a split routing system for directing the flow of the oxygen-containing gas component of the gaseous CPOX reaction mixture, where one portion of the oxygen-containing gas can be combined with the reformable fuel in order to provide a relatively fuel-rich stream

which can be resistant to flashing and another portion of the oxygen-containing gas can be combined downstream with the fuel-rich stream in order to provide a gaseous CPOX reaction mixture that can be within a preset molar ratio of oxygen to carbon for a desired CPOX reforming reaction. For example, the split routing system can include an oxygen-containing gas conduit including a branch conduit, where the oxygen-containing gas conduit can provide fluid communication between a source of oxygen-containing gas and the vaporizer and the branch conduit can provide fluid communication between the source of oxygen-containing gas and a mixing zone downstream of the vaporizer. The oxygen-containing gas conduit and the branch conduit can split or divide the delivery of an oxygen-containing gas from the source of oxygen-containing gas to the vaporizer and the mixing zone downstream of the vaporizer.

**[0120]** In particular embodiments, a vaporizer for vaporizing liquid reformable fuel is in fluid communication with the inlets of the CPOX reactor units. The vaporizer can be operated to eliminate or reduce the risk of heating the fuel to a temperature at or above its flash point and/or causing appreciable pyrolysis of fuel.

**[0121]** In various embodiments, an igniter for initiating the CPOX reaction within an array of CPOX reactor units, for example, during a start-up mode of operation of a liquid fuel CPOX reformer, is in thermal communication with a CPOX catalyst, for example, in a CPOX reaction zone. The igniter can initiate a CPOX reaction in at least one CPOX reactor unit proximate thereto with heat of exotherm within the at least one CPOX reactor unit in turn initiating the CPOX reaction within one or more other CPOX reactor units within the array.

**[0122]** In some embodiments, a manifold or plenum, in fluid communication with the inlets of CPOX reactor units, can be configured to provide a more uniform distribution of gaseous CPOX reaction mixture, for example, at a substantially uniform composition, at a substantially uniform temperature, and/or a substantially uniform rate, to inlets of CPOX reactor units.

**[0123]** In certain embodiments, a manifold can have a housing or enclosure that defines a manifold chamber. A manifold or manifold chamber can include a gas

distributor, for example, a gas distributor within the manifold chamber. In particular embodiments, the gas distributor can be considered a gaseous fuel CPOX reaction mixture distributor. The housing or enclosure can be fabricated from a relatively low cost, readily moldable thermoplastic or thermosetting resin and/or can feature “cold seal” connections between its outlets and the inlets of the CPOX reactor units.

**[0124]** More specifically, a manifold can be in fluid communication with the inlet of at least one CPOX reactor unit, where the manifold includes a manifold housing. The manifold housing can define a manifold chamber. The manifold can include one or more additional components such as a gaseous CPOX reaction mixture distributor, a heater, and a cavity including a seal.

**[0125]** The gaseous CPOX reaction mixture distributor can be disposed within, and extending for at least a majority of the length of, the manifold chamber, where is in fluid communication with a gaseous reactants conduit, and the gaseous CPOX reaction mixture distributor includes one or more outlets located opposite the inlet of the CPOX reactor unit. That is, a gaseous CPOX reaction mixture distributor can include a housing defining a chamber, for example, a closed-ended hollow tube or other structure, typically having a length greater than its width and depth. The housing can define a one or more outlets providing fluid communication between the interior of the housing or chamber and the exterior of the housing. The one or more outlets can be along one side of the gaseous CPOX reaction mixture distributor or form a line or longitudinal array along its longitudinal axis, for example, in the case of a tubular gaseous CPOX reaction mixture distributor. When positioned in the manifold chamber, the one or more outlets of the gaseous CPOX reaction mixture distributor usually are located opposite the inlets of the CPOX reactor units. In such a design, the CPOX reaction mixture is initially introduced into the manifold chamber in a direction away from the inlets of the CPOX reactors units, for example, downward towards the bottom of the manifold chamber and then will flow towards the inlets of the CPOX reactor units, for example, flowing upwards to the inlets.

**[0126]** A heater can be in thermal communication with the manifold chamber. The heater can be an electrical resistance heater. The heater can be disposed within

the manifold chamber. In addition, the heater can include a passive heating element such as at least one thermally conductive element in thermal communication with the manifold and a CPOX reaction zone of CPOX reactor unit thereby to transfer heat of exotherm from the CPOX reaction zone and/or CPOX reactor unit to the manifold.

**[0127]** The manifold housing can define one or more cavities. A seal can be disposed within or adjacent to the cavity, where the seal can engage the inlet of the CPOX reactor unit and can provide a gas-tight seal between the manifold housing and the inlet. Where more than one CPOX reactor unit is present, the manifold housing can include the same number of cavities as CPOX reactor units such that each CPOX reactor unit can be in fluid communication with the manifold chamber and each cavity can include a seal securing a respective CPOX reactor unit. The cavities of the manifold housing can be sized and arranged in the same configuration as the inlets of the CPOX reactor units to provide a match for each cavity to an inlet. The seal can be a gasket. The manifold housing can be fabricated from or include a material that remains thermally and mechanically stable at the temperature of operation of the CPOX reactor units.

**[0128]** In particular embodiments, the walls of the CPOX reactor units can include at least two regions, a first, or upstream, region being substantially devoid of CPOX catalyst and enclosing an essentially CPOX reaction-free zone of relatively low operating temperature and a second, or downstream, region containing CPOX catalyst and enclosing a CPOX reaction zone of relatively high operating temperature.

**[0129]** In various embodiments, a blower system featuring an interconnected series of individual centrifugal blower units can be used to introduce a flow of oxygen-containing gas into the reformer and/or can provide for gas flow within the CPOX reformer, for example, for heat transfer, which can include heating and/or cooling of structure(s) and thermal zone(s).

**[0130]** In some embodiments, a control system can be adapted to control the operations of the CPOX reformer in its start-up, steady-state, and/or shut-down modes.

**[0131]** A liquid fuel CPOX reformer of the present teachings can include a conduit for routing gas toward the inlets of the CPOX reactor units. The conduit can include an inlet for oxygen-containing gas; an inlet for liquid reformable fuel, vaporized liquid reformable fuel, gaseous reformable fuel and combinations thereof; a mixing zone in which oxygen-containing gas and vaporized liquid reformable fuel combine to provide a gaseous CPOX reaction mixture; and an outlet for gaseous CPOX reaction mixture. The conduit can be generally U-shaped.

**[0132]** A liquid fuel CPOX reformer of the present teachings can include at least one source of heat. For example, a liquid fuel CPOX reformer can include a first heater unit operable during a start-up mode of operation of the liquid fuel CPOX reformer to heat oxygen-containing gas introduced into a conduit to an initial elevated temperature. A liquid fuel CPOX reformer also can include a second heater unit operable during start-up mode and steady-state modes of operation of the liquid fuel CPOX reformer to heat oxygen-containing gas previously heated to an initial elevated temperature to a further elevated temperature.

**[0133]** A liquid fuel CPOX reformer of the present teachings can include a thermally linked heat transfer zone operable during a steady-state mode of operation of the liquid fuel CPOX reformer to heat oxygen-containing gas to an initial elevated temperature prior to or following introduction of the oxygen-containing gas into a conduit.

**[0134]** For example, in some embodiments, a first source of heat and a first heat transfer zone (or a first heating zone) thermally linked thereto operable during a steady-state mode of operation of the reformer to heat oxygen-containing gas to an initial elevated temperature following introduction of the oxygen-containing gas into the conduit, the first source of heat and first heat transfer zone thermally linked thereto comprising CPOX reaction zones of CPOX reactor units in thermal communication with a CPOX heat transfer zone disposed within the conduit proximate to or coincident with the first heater unit and associated first heating zone and upstream from the second heater and associated second heating zone, heat of

exotherm from the CPOX reaction occurring within the CPOX reaction zones being transferred to oxygen-containing gas passing through the CPOX heat transfer zone.

[0135] In addition, certain embodiments can include a second source of heat and a second heat transfer zone (or a second heating zone) thermally linked thereto operable during a steady-state mode of operation of the reformer to heat oxygen-containing gas to an initial elevated temperature prior to introduction of the oxygen-containing gas into the conduit, the second source of heat and second heat transfer zone thermally linked thereto comprising a heat-producing source other than the reformer and heat transfer zone in thermal communication therewith, such heat-producing source and heat transfer zone being disposed externally to the conduit, heat recovered from the heat-producing source being transferred to oxygen-containing gas passing through the heat transfer zone prior to introduction of the oxygen-containing gas into the conduit.

[0136] A liquid fuel CPOX reformer of the present teachings can include a mixer, for example, to mix oxygen-containing gas and vaporized liquid reformable fuel. The mixer can be a static mixer or a dynamic mixer, for example, a fluid mixing device such as described in co-pending, co-owned U.S. Patent Application No. 14/335,463, entitled, "Mixing Reformable Fuels and an Oxygen-Containing Gas and/or Steam," which is incorporated by reference herein for all purposes including its teachings relating to a fluid mixing device and methods of operating the same to provide a CPOX reaction mixture applicable to the present teachings.

[0137] A liquid fuel CPOX reformer of the present teachings can include a CPOX reformat processing unit or device, for example, a carbon monoxide removal device to reduce the carbon monoxide content of the product reformat. A CPOX reformat processing unit or device can include a water gas shift converter, a preferential oxidation reactor, and/or a hydrogen-selective membrane for separating reformat into a hydrogen stream and a carbon monoxide-containing stream.

[0138] In various embodiments, a liquid fuel CPOX reformer of the present teachings can have one or more outlets of CPOX reactor units directly connected to inlet(s) of another device, for example, a fuel cell. In some embodiments, outlets of

CPOX reactor units can be in fluid communication with a manifold or similar component or device that can combine the effluent stream from multiple CPOX reactor unit outlets and distribute such combined effluent to an equal, a greater, or a lesser number of inlets of another device, for example, an anode of a fuel cell.

**[0139]** A liquid fuel CPOX reformer of the present teachings can include thermal insulation for reducing heat loss from the tubular CPOX reactor units and other heat radiating components of the reformer.

**[0140]** A liquid fuel CPOX reformer of the present teachings can include a gaseous stream driver for driving gaseous flow within and through the reformer. A liquid fuel CPOX reformer of the present teachings can include a fuel pump. Examples of a pump such as a fuel pump include a metering pump, a rotary pump, an impeller pump, a diaphragm pump, a peristaltic pump, a positive displacement pump, a gear pump, a piezoelectric pump, an electrokinetic pump, an electroosmotic pump and a capillary pump.

**[0141]** A liquid fuel CPOX reformer of the present teachings can include one or more sensor assemblies for monitoring and controlling one or more reformer operations. Examples of sensor assemblies include flow meters, thermocouples, thermistors, and resistance temperature detectors. A liquid fuel CPOX reformer of the present teachings also can include a control system for automating the operations of the reformer in its start-up, steady-state, and/or shut-down modes. The control system can include a plurality of sensor assemblies in communication with a controller.

**[0142]** A liquid fuel CPOX reformer of the present teachings can include heat transfer means in thermal communication with the CPOX reactor units. The heat transfer means can transfer heat from the CPOX reactor units during a steady-state mode of operation of the liquid fuel CPOX reformer, for example, to maintain the temperature within the CPOX reaction zone of the CPOX reactor units within a preset range. Heat transfer means can include a blower, for example, to direct a coolant stream against exposed exterior surfaces of the CPOX reactor units and/or against a heat-radiative member of a heat conducting assembly in thermal communication with

exposed surfaces of CPOX reactor units. A liquid fuel CPOX reformer of the present teachings also can include a blower for other purposes. For example, a blower can introduce oxygen-containing gas into a conduit and/or drive gaseous flow within a CPOX reactor unit.

**[0143]** A blower can include a series of blower units. A blower or blower unit in a series can include a casing having an axial inlet and a radial outlet, an impeller disposed within the casing for drawing in a gas, for example, an oxygen-containing gas such as air, in the axial inlet and expelling the gas through the radial outlet; and a motor for driving the impeller. In certain embodiments, the blower can draw in a gas at a first pressure and expel the gas at a second, for example, higher, pressure. A blower also can include a duct to contain the outlet of at least one blower unit in the series with the inlet of at least one other blower unit in the series. For example, a series of blowers can include the blower systems as described in co-owned U.S. Patent Application Publication No. 2012/0328969, entitled, "Centrifugal Blower System and Fuel Cell Incorporating Same," which is incorporated by reference herein for all purposes including its teachings relating to a blower system and methods of operating the same as applicable to the present teachings.

**[0144]** A liquid fuel CPOX reformer of the present teachings can include a source of electrical current for powering electrical energy-consuming reformer components and/or auxiliary CPOX reformer components. The source of electrical current can include a rechargeable battery and battery recharger.

**[0145]** In another aspect, methods of CPOX reforming are provided. More specifically, the present teachings provide methods of CPOX reforming of a liquid (reformable) fuel to a hydrogen-rich reformat or product. To that end, in various embodiments, the methods of CPOX reforming include:

- a) in a start-up mode:
  - (i) introducing oxygen-containing gas into a conduit for routing gas toward the inlet of each of a plurality of CPOX reactor units, the conduit comprising an inlet for oxygen-containing gas, an inlet for liquid reformable fuel and an outlet for heated gaseous CPOX reaction mixture in gaseous flow

communication with the inlets of the CPOX reactor units, each CPOX reactor unit comprising an elongate tube having a wall with internal and external surfaces, the wall enclosing an open gaseous flow passageway with at least a section of the wall having CPOX catalyst disposed therein and/or comprising its structure, such catalyst-containing wall section and open gaseous flow passageway enclosed thereby defining a gaseous phase CPOX reaction zone, the catalyst-containing wall section being gas-permeable to allow gaseous CPOX reaction mixture to diffuse therein and product reformat to diffuse therefrom while remaining structurally stable under CPOX reaction conditions,

- (ii) heating the oxygen-containing gas,
- (iii) introducing liquid reformable fuel into the conduit,
- (iv) vaporizing the liquid reformable fuel introduced into the conduit, the vaporized fuel combining with heated oxygen containing gas from step (ii) to provide heated gaseous CPOX reaction mixture,
- (v) introducing heated gaseous CPOX reaction mixture from step (iv) into the inlets of the CPOX reactor units, and
- (vi) initiating CPOX of the gaseous CPOX reaction mixture within the CPOX reaction zones of the CPOX reactor units thereby commencing the production of hydrogen-rich reformat; and,

b) in a steady-state mode:

- (vii) introducing oxygen-containing gas into the conduit, the oxygen-containing gas having been heated prior to or following its introduction into the conduit by operation of the at least one source of heat and thermally linked heat transfer zone,
- (viii) introducing liquid reformable fuel into the conduit,
- (ix) vaporizing the liquid reformable fuel, the vaporized fuel combining with heated oxygen-containing gas from step (vii) to provide heated gaseous CPOX reaction mixture,

- (x) introducing heated gaseous CPOX reaction mixture from step (ix) into the inlets of the CPOX reactor units,
- (xi) discontinuing initiating step (vi) prior to, during or following step (ix), and
- (xii) maintaining the CPOX reaction within the CPOX reaction zones of the CPOX reactor units thereby continuing the production of hydrogen-rich reformat.

**[0146]** In some embodiments, the methods can include, for example, in step (vii), heating oxygen-containing gas at ambient temperature or at an ambient temperature prior to its introduction into a conduit using heat from an external heat-producing source. In various embodiments, the methods can include heating further the oxygen-containing gas from a first temperature to a second elevated temperature, for example, using heat of exotherm recovered from CPOX occurring within the CPOX reaction zones of the CPOX reactor units.

**[0147]** In certain embodiments, the methods can include, for example, in each of steps (iv) and (ix), vaporizing liquid reformable fuel using heat contained within the heated oxygen-containing gas, for example, from steps (ii) and (vii), respectively. In particular embodiments, the methods can include heating the liquid reformable fuel prior to its introduction into the conduit. In some embodiments, the methods can include making the heated gaseous CPOX mixture, for example, from each of steps (iv) and (ix), more uniform in composition prior to its introduction into the inlets of the CPOX reactor units, for example, in steps (v) and (x), respectively. In various embodiments, the methods can include distributing the heated gaseous CPOX reaction mixture of more uniform composition to the inlets of the CPOX reactor units and/or distributing the heated gaseous CPOX reaction mixture to the inlets of the CPOX reactor units at a more uniform temperature, for example, in steps (v) and (x), respectively. In some embodiments, the methods include distributing the heated gaseous CPOX reaction mixture to the inlets of the CPOX reactor units such that the difference in flow rate of the CPOX reaction mixture within any two CPOX reactor units is not greater than about 20 % and/or the difference in the temperature of CPOX

reaction mixture entering the inlets of any two CPOX reactor units in not greater than about 10 %.

**[0148]** In certain embodiments of the methods of the present teachings, the methods can include, for example, in step (vi), initiating CPOX of the gaseous CPOX reaction mixture within the CPOX reaction zones of the CPOX reactor units by operating an igniter, where radiant heat output from the igniter can be transmitted to an exposed section of at least one CPOX reactor unit in proximity thereto to initiate the CPOX reaction therein, radiant heat produced by the CPOX reaction occurring within the CPOX reaction zone of the at least one CPOX reactor unit in turn initiating the CPOX reaction within at least one other CPOX reactor unit within the chamber until in such manner the CPOX reaction has been initiated in all of the CPOX reactor units in the chamber.

**[0149]** In various embodiments, the methods can include, for example, in step (v), adjusting the molar ratio of oxygen to carbon of the gaseous CPOX reaction mixture to correspond to that of a fuel-lean CPOX reaction mixture. In certain embodiments, the methods can include, for example, in step (x), adjusting the molar ratio of oxygen to carbon of the gaseous CPOX reaction mixture to correspond to that of a fuel-rich CPOX reaction mixture. In particular embodiments, the methods can include routing or diverting a portion of the oxygen-containing gas introduced into the conduit to bypass vaporization sections, for example, each of vaporizing steps (iv) and (ix), and to merge with heated gaseous CPOX reaction mixture from these steps. In certain embodiments, the methods can include, prior to the merger of the oxygen-containing gas with the gaseous CPOX reaction mixture, making or adjusting the gaseous CPOX reaction mixture to be more uniform in composition. In particular embodiments, following the merger of the oxygen-containing gas with the gaseous CPOX reaction mixture, the methods can include making or adjusting the merged gas to be more uniform in composition.

**[0150]** In some embodiments, the methods of the present teachings include providing gas flow by a blower system including a series of blower units, each blower unit in the series comprising a casing having an axial inlet and radial outlet, an

impeller disposed within the casing for drawing an oxygen-containing gas at a first pressure in the inlet and expelling oxygen-containing gas at a higher pressure through the outlet and a motor for driving the impeller, and a duct containing the outlet of at least one blower unit in the series in the inlet of at least one other blower unit in the series, at least one blower unit in the series providing from 60 to 90% of the target gas flow of the blower system and the at least one other blower unit in the series providing the balance of the target gas flow of the blower system. In various embodiments, the methods can include a back pressure in the CPOX reformer of not more than about three (3) inches of water.

**[0151]** In various methods of the present teachings, introducing a gaseous CPOX reaction mixture into an inlet of a CPOX reactor unit can include introducing an oxygen-containing gas into a conduit for routing fluids toward the inlet of a CPOX reformer unit; heating a stream of the oxygen-containing gas with a first source of heat comprising an electric heater disposed in the conduit to provide a stream of heated oxygen-containing gas; and introducing a liquid reformable fuel into the stream of heated oxygen-containing gas in, through, at or past a vaporizer to provide the gaseous CPOX reaction mixture. The methods can include heating the stream of the oxygen-containing gas and/or the stream of heated oxygen-containing gas with a second source of heat, where the second source of heat is in thermal communication with the conduit and comprises heat of exotherm from the CPOX reactor units and/or a hydrogen reformat-consuming device external to the CPOX reactor units. The electric heaters can be electrical resistance heaters.

**[0152]** In some embodiments, the methods can include heating and/or cooling upstream of the vaporizer the stream of oxygen-containing gas and/or the stream of heated oxygen-containing gas. In various embodiments, for example, where a thermally-regulating assembly is used, the temperature of the stream of oxygen-containing gas and/or the stream of heated oxygen-containing gas heated by the second source of heat (exotherm of CPOX reaction or of a hydrogen-reformat-consuming device external to the CPOX reformer) can be thermally controlled and cooled or lowered in temperature, if necessary, to prevent a runaway thermal situation where the heat of exotherm becomes too hot for the operating system.

**[0153]** In particular embodiments, the methods include heating a stream of heated oxygen-containing gas with a third source of heat including an electric heater, where the third source of heat is disposed in the conduit downstream from the first source of heat. In certain embodiments, the methods can include discontinuing heating the stream of oxygen-containing gas with the first source of heat. The methods can include reducing or discontinuing heating the stream of oxygen-containing gas and/or the stream of heated oxygen-containing gas with the third source of heat.

**[0154]** In particular embodiments, the methods include monitoring at least one of the flow rate of the stream of heated oxygen-containing gas, the flow rate of liquid reformable fuel, the temperature of the vaporizer, the temperature of the stream of heated oxygen-containing gas and the temperature of the liquid reformable fuel; and controlling the vaporization of the liquid reformable fuel in response to the results of the monitoring.

**[0155]** The methods can include adjusting the heat supplied by one or more of the first source of heat, the second source of heat, the third source of heat, and adjusting the heat and/or coldness supplied by the thermally-regulating assembly. The methods can include heating the liquid reformable fuel using the second source of heat and/or the third source of heat, when present, prior to introducing the liquid reformable fuel into the vaporizer. In particular embodiments, the liquid reformable fuel introduced into the stream of heated oxygen-containing gas vaporizes on contact with the heated oxygen-containing gas. The methods can include monitoring one or more of the flow rate of the stream of heated oxygen-containing gas, the flow rate of liquid reformable fuel, the temperature of the vaporizer, the temperature of the stream of heated oxygen-containing gas and the temperature of the liquid reformable fuel. Based on the feedback from the monitoring, the methods can include controlling the vaporization of the liquid reformable fuel in response. For example, controlling the vaporization can include adjusting the heat supplied by the second source of heat and/or the third source of heat and/or the heat and/or coldness supplied by the thermally-regulating assembly.

[0156] Liquid fuel CPOX reformers and methods of CPOX reforming according to the present teachings generally are described above and elsewhere herein. The following description with reference to the figures embellishes upon certain of these features and others of liquid fuel CPOX reformers and CPOX reforming processes of the present teachings and should be understood to discuss various and specific embodiments without limiting the essence of the invention and that can be applicable to the discussion above.

[0157] Referring now to the drawings, **FIG. 2A** illustrates one embodiment of liquid fuel CPOX reformer in accordance with the present teachings where an oxygen-containing gas component of a CPOX reaction mixture is heated by the heat of exotherm resulting from CPOX reforming during a steady-state mode of operation of the liquid fuel CPOX reformer.

[0158] As shown in **FIG. 2A**, liquid fuel CPOX reformer **200** includes centrifugal blower **202** for introducing oxygen-containing gas, exemplified here and in the other embodiments of the present teachings by air, into conduit **203**, and for driving this and other gaseous streams (inclusive of vaporized fuel-air mixture(s) and hydrogen-rich reformates) through the various passageways, including open gaseous flow passageways, of the reformer. Conduit **203** can include flow meter **204** and thermocouple **205**. These and similar devices can be placed at various locations within a liquid fuel CPOX reformer in order to measure, monitor and control the operation of the liquid fuel CPOX reformer as more fully explained in connection with the control system illustrated in **FIG. 3A**.

[0159] In a start-up mode of operation of exemplary liquid fuel CPOX reformer **200**, air at ambient temperature, introduced by blower **202** into conduit **203**, passes through first heating zone **206**, where the air is initially heated by first heater **207**, for example, of the electrical resistance type, to within a preset, or targeted, first range of elevated temperature at a given rate of flow. The initially heated air then passes through heat transfer zone **208** which in the steady-state mode of operation of CPOX reformer **200** is heated by heat of exotherm recovered from the CPOX reaction occurring within CPOX reaction zones **210** of tubular CPOX reactor units **209**. Once

such steady-state operation of reformer **200** is achieved, i.e., upon the CPOX reaction within CPOX reactor units **209** becoming self-sustaining, the thermal output of first heater **207** can be reduced or its operation discontinued since the incoming air will have already been heated by passage through heat transfer zone **208** to within, or approaching, its first range of elevated temperature.

[0160] Continuing further downstream within conduit **203**, the air which has initially been heated, either by passage through first heating zone **206** during a start-up mode of operation or by passage through heat transfer zone **208** during a steady-state mode of operation, passes through second heating zone **211** where it is further heated by second heater **212**, which can also be of the electrical resistance type, to within a second range of elevated temperature. A heater can operate to top-off the temperature of the previously heated air thereby satisfying several operational requirements of liquid fuel CPOX reformer, namely, assisting in the regulation and fine-tuning of the thermal requirements of the reformer on a rapid response and as-needed basis, providing sufficient heat for the subsequent vaporization of liquid reformable fuel introduced further downstream into conduit **203** and providing heated gaseous CPOX reaction mixture.

[0161] Liquid reformable fuel, exemplified here and in the other embodiments of the present teachings by diesel, is continuously introduced via pump **213** through fuel line **214** equipped with optional flow meter **215** and optional flow control valve **216** and into conduit **203** where the fuel is vaporized by vaporizer system **217** utilizing heat from the heated air flowing from second heating zone **211**. The vaporized, i.e., gaseous, fuel combines with the stream of heated air in mixing zone **218** of conduit **203**. A mixer, for example, a static mixer such as in-line mixer **219**, and/or vortex-creating helical grooves formed within the internal surface of conduit **203**, or an externally powered mixer (not shown), are disposed within mixing zone **218** of conduit **203** in order to provide a more uniform fuel-air gaseous CPOX reaction mixture than would otherwise be the case.

[0162] The heated vaporized fuel-air mixture (heated gaseous CPOX reaction mixture) enters manifold, or plenum, **220** which functions to distribute the reaction

mixture more evenly and, for example, at a more uniform temperature, into tubular CPOX reactor units **209**. While the conduit and the manifold will ordinarily be surrounded by thermal insulation (e.g., insulation **410** of liquid fuel CPOX reformer **400** illustrated in **FIG. 4A**), the CPOX reaction mixture can still undergo a drop in temperature due to heat loss through the walls of the manifold, which typically has a greater volume, and hence a greater wall surface area, than that of a comparable length of the conduit. Another factor that can cause a drop in the temperature of the CPOX reaction mixture within a manifold is the reduction in pressure and velocity which the mixture undergoes as it exits the conduit and enters the larger space of the manifold.

**[0163]** Reductions in the temperature of a CPOX reaction mixture due to either of these factors, particularly those occurring in regions of the reaction mixture that are proximate to or in contact with walls, corners and/or other recesses of the manifold, can induce localized condensation of vaporized fuel. To minimize the possibility of such condensation, a manifold can be provided with means for maintaining the temperature of the gaseous CPOX reaction mixture above the condensation threshold of its vaporized fuel component. For example, as shown in **FIG. 2A**, heater **221**, of the electrical resistance type, and thermocouple or thermistor probe **222** for purposes of temperature control, are disposed within manifold **220** in order to accomplish this objective. As an alternative to a heater or in addition thereto, a reformer can be provided with thermally conductive structure(s), (e.g., thermally conductive elements **434** of the CPOX reformer illustrated in **FIG. 4A**) for transferring heat of exotherm recovered from the CPOX reaction occurring within CPOX reaction zones of tubular CPOX reactor units to such locations within a manifold where the potential for condensation of fuel vapor can be greatest, for example, wall surfaces in the vicinity of the fuel-air outlets and/or other sites such as corners and other recesses of the manifold that could cause localized condensation of vaporized fuel.

**[0164]** From manifold **220**, the heated CPOX reaction mixture is introduced into tubular CPOX reactor units **209**, a detailed description of one embodiment of which is presented herein in connection with tubular CPOX reactor units **408** of manifold portion **450** illustrated in **FIG. 4I**. In a start-up mode of operation of CPOX reformer

200, igniter 223 initiates the CPOX reaction of the gaseous CPOX reaction mixture within CPOX reaction zones 210 of tubular CPOX reactor units 209 thereby commencing the production of hydrogen-rich reformat. Once steady-state CPOX reaction temperatures have been achieved (e.g., 250 °C to 1,100 °C), the reaction becomes self-sustaining and operation of the igniter can be discontinued.

Thermocouples 224 and 225 are provided to monitor the temperatures of, respectively, the vaporization operation occurring within conduit 203 and the CPOX reaction occurring within CPOX reactor units 209, the temperature measurements being relayed as monitored parameters to reformer control system 226.

[0165] Reformer 200 can also include a source of electrical current, for example, rechargeable lithium-ion battery system 227, to provide power for its electrically driven components such as blower 202, flow meters 204 and 215, heaters 207, 212 and 221, liquid fuel pump 213, flow control valve 216, igniter 223, and thermocouples 205, 222, 224 and 225 and, if desired, to store surplus electricity for later use.

[0166] If desired, product effluent or hydrogen-rich reformat from a liquid CPOX reformer can be introduced into one or more conventional or otherwise known carbon monoxide removal devices 228 for the reduction of its carbon monoxide (CO) content, for example, where the product effluent is to be introduced as fuel to a fuel cell stack utilizing a catalyst that is particularly susceptible to poisoning by CO, for example, a polymer electrolyte membrane fuel cell. Thus, for example, the product effluent can be introduced into a water gas shift (WGS) converter wherein CO is converted to carbon dioxide (CO<sub>2</sub>) while at the same time producing additional hydrogen, or the product effluent can be introduced into a reactor wherein CO is made to undergo preferential oxidation (PROX) to CO<sub>2</sub>. CO reduction can also be carried out employing a combination of these processes, for example, WGS followed by PROX and *vice versa*.

[0167] It is also within the scope of the present teachings to reduce the level of CO in the product reformat by passage of the product reformat through a known or conventional clean-up unit or device equipped with a hydrogen-selective membrane

providing separation of the product reformat into a hydrogen stream and a CO-containing by-product stream. Units/devices of this kind can also be combined with one or more other CO-reduction units such as the aforementioned WGS converter and/or PROX reactor.

[0168] In contrast to liquid fuel reformer **200** of **FIG. 2A** in which air is heated within heat transfer zone **208** of conduit **203** by heat of exotherm recovered from CPOX reactor units **209** during a steady-state mode of operation, in exemplary liquid fuel CPOX reformer **250** of **FIG. 2B**, air introduced via centrifugal blower **252** into conduit **253** is heated by passage through heat exchanger **254** which is supplied with waste heat (hot combustion gas exhaust) recovered from an external heat-producing source, for example, a fuel cell stack (not shown). In all other respects, the components of CPOX reformer **250** of **FIG. 2B** and their functions are essentially the same as those of CPOX reformer **200** of **FIG. 2A**.

[0169] Control system **300** illustrated in **FIG. 3A** is provided for controlling the operations of a liquid fuel CPOX reformer in accordance with the present teachings. As shown in **FIG. 3A**, control system **300** includes controller **301** to manage liquid fuel CPOX reformer **302** in its start-up, steady-state, and shut-down modes of operation. The controller can be software operating on a processor. However, it is within the scope of the present teachings to employ a controller that is implemented with one or more digital or analog circuits, or combinations thereof.

[0170] Control system **300** further includes a plurality of sensor assemblies, for example, fuel pressure meter **304**, air pressure meter **309**, mixing zone thermocouple **313** and CPOX reaction zone thermocouple **314**, in communication with controller **301** and adapted to monitor selected operating parameters of CPOX reformer **302**. In response to input signals from the sensor assemblies, user commands from a user-input device and/or programmed subroutines and command sequences, a controller can manage the operations of a liquid fuel CPOX reformer. More specifically, a controller can communicate with a control signal-receiving portion of the desired section or component of a liquid fuel CPOX reformer by sending command signals thereto directing a particular action. Thus, for example, in response to flow rate input

signals from pressure meters **304** and **309** and/or temperature input signals from thermocouples **313** and **314**, controller **301** can send control signals to fuel pump **303** and/or fuel flow control valve **305**, for example, to control the flow of fuel through fuel line **306** to conduit **307**, to centrifugal blower **308** to control the flow of air into conduit **307** and drive the flow of heated gaseous CPOX reaction mixture within and through CPOX reformer **302**, to heater **310** to control its thermal output, to igniter **311** to control its on-off states, and to battery/battery recharger system **312** to manage its functions.

[0171] The sensor assemblies, control signal-receiving devices and communication pathways herein can be of any suitable construction and of those known in the art. The sensor assemblies can include any suitable sensor devices for the operating parameters being monitored. For example, fuel flow rates can be monitored with any suitable flow meter, pressures can be monitored with any suitable pressure-sensing or pressure-regulating device, and the like. The sensor assemblies can also, but do not necessarily, include a transducer in communication with the controller. The communication pathways will ordinarily be wired electrical signals but any other suitable form of communication pathway can also be employed.

[0172] In **FIG. 3A**, communication pathways are schematically illustrated as single- or double-headed arrows. An arrow terminating at controller **301** schematically represents an input signal such as the value of a measured flow rate or measured temperature. An arrow extending from controller **301** schematically represents a control signal sent to direct a responsive action from the component at which the arrow terminates. Dual-headed pathways schematically represent that controller **301** not only sends command signals to corresponding components of CPOX reformer **302** to provide a determined responsive action, but also receives operating inputs from CPOX reformer **302** and mechanical units such as fuel pump **303**, fuel control valve **305** and blower **308** and measurement inputs from sensor assemblies such as pressure meters **304** and **309** and thermocouples **313** and **314**.

[0173] **FIG. 3B** presents a flow chart of an exemplary control routine that can be executed by a controller of a control system to automate the operations of a liquid

fuel CPOX reformer. The flow chart can be executed by a controller at a fixed interval, for example, every 10 milliseconds or so. The control logic illustrated in **FIG. 3B** performs several functions including the management of gaseous flows, heating, fuel vaporization and CPOX reaction temperatures in start-up and steady-state modes of operation and management of the procedure for the shut-down mode of reformer operation.

[0174] As shown in the various views of exemplary liquid fuel CPOX reformer **400** and components thereof illustrated in **FIGS. 4A-4O**, which are representative of further embodiments of the present teachings, air as an oxygen-containing gas is introduced at ambient temperature and at a preset mass flow rate via centrifugal blower system **402**, shown in greater detail in **FIGS. 4N** and **4O**, through inlet **403** of main conduit **404**, which includes a generally U-shaped conduit section favoring compact design. The ambient temperature air is initially heated in the start-up mode operation of the reformer to within a preset range of elevated temperature by passage through first heating zone **405** supplied with heat from first heater unit **406**. First heater unit **406** and second heater unit **413**, downstream therefrom, can be of a conventional or otherwise known electrical resistance type rated, for example, at from 10 to 80 watts, or even greater depending upon designed range of fuel processing capacity of the reformer. Such heaters are capable of raising the temperature of ambient air introduced into a conduit to a desired level for a relatively wide range of CPOX reformer configurations and operating capacities. During the steady-state mode of operation of reformer **400**, first heater unit **406** can be shut off, the air introduced into main conduit **404** then being initially heated within heat transfer zone **407** by heat of exotherm recovered from CPOX reaction zones **409** of elongate tubular gas-permeable CPOX reactor units **408**, the structural and compositional details of which are described in greater detail in **FIGS. 4I-4M**. In this manner, the temperature of the air introduced into a conduit can be increased from ambient to within some preset elevated range of temperature with the particular temperature being influenced by a variety of design, i.e., structural and operational factors as those skilled in the art will readily recognize.

[0175] Thermal insulation 410, for example, of the microporous or alumina-based refractory type, surrounds most of main conduit 404 and those portions of CPOX reactor units 408 corresponding to their CPOX reaction zones 409 in order to reduce thermal losses from these components.

[0176] As the heated air stream flows downstream within main conduit 404 (which in the depicted configuration also can be referred to herein as an oxygen-containing gas conduit), it can be split, or divided, into two streams with one stream (e.g., a primary (fluid) stream) continuing to course through main conduit 404 and the other stream (e.g., a secondary (fluid) stream) being diverted into branch conduit 411 from which it exits to re-enter main conduit 404 at merger zone 421 and merge with vaporized fuel-air mixing passing from first mixing zone 420 (having a first static mixer and/or a helically-grooved internal wall surface disposed therein). The merged gases then enter second mixing zone 422 downstream of the vaporizer (likewise having a second static mixture and/or a helically-grooved internal wall surface disposed therein) to provide a gaseous CPOX reaction mixture of fairly uniform composition for introduction through outlet 425 into gas distributor 427 of manifold 426, the structure and operation of which are more fully described herein.

[0177] In some embodiments, rather than a single conduit that includes branching, two individual or independent conduits can be used to achieve the same purpose where each conduit has a source of oxygen-containing gas in fluid communication with the respective conduit. That is, a primary fluid stream from a first source of oxygen-containing gas can pass through a first (main) conduit and to the vaporizer, usually at a reduced volumetric flow rate to maintain a higher fuel:air ratio up to and through the vaporizer. A secondary fluid stream from a second source of oxygen-containing gas can pass through a second conduit and merge with the primary fluid stream and vaporized liquid reformable fuel mixture in the first conduit downstream of the vaporizer but upstream of the inlets of the CPOX reactor units and/or a manifold thereby to delivery the desired O:C ratio of gaseous CPOX reaction mixture to the CPOX reactor units.

[0178] **FIG. 4P** is a longitudinal cross section view of such an embodiment of a liquid CPOX reformer in accordance with the present teachings similar to **FIG. 4A** but where two sources of oxygen-containing gas **402'**, **467** are present, each in fluid communication with merger zone **421'** via conduit **404'** and conduit **411'**. Like reference numerals generally refer to like parts in **FIGS. 4A** and **4P** and will not be repeated here.

[0179] In either case, by splitting the total amount of air for the desired CPOX reaction into two streams, the amount of vaporized liquid fuel component contained in the fuel-air mixture that starts to form as just-vaporized fuel and heated air begin to combine can be kept high in proportion to the air component thus eliminating or reducing the possibility that some region(s) of this non-uniform initial fuel-air mixture will contain a concentration of air that is sufficiently high to support ignition and consequent coke formation. Once the initial fuel-air mixture passes through the first static mixer disposed within a first mixing zone thereby attaining a degree of compositional uniformity that makes the presence of ignition-inducing regions of relatively high air concentration much less likely, the somewhat more uniform fuel-air mixture then can merge with the second heated air stream (or secondary (fluid) stream) exiting a branch conduit at a merger zone thereby satisfying the preset O to C molar ratio of the desired CPOX reaction mixture. This fuel-air mixture then can flow through the second static mixer disposed within a mixing zone to provide a more compositionally uniform gaseous CPOX reaction mixture just prior to the mixture entering a gas distributor of a manifold.

[0180] To raise the temperature of the air that had been initially heated by passage through first heating zone **405** and/or heat transfer zone **407**, as the initially heated air continues to flow downstream in main conduit **404**, the initially heated air is routed through second heating zone **412** supplied with heat from second heater unit **413**. Because the second heater unit need only increase the temperature of the initially heated air by a relatively small extent, it can function as an incremental heater capable of making the typically small adjustments in air temperature that are conducive to precise and rapid thermal management of the reformer both with regard

to the functioning of its fuel vaporization system, described herein, and its tubular CPOX reactor units.

[0181] A liquid reformable fuel such as any of those mentioned above, and exemplified in this and the other embodiments of the present teachings by diesel fuel, is introduced via fuel line **414** terminating within main conduit **404** in liquid fuel spreader device **415**, for example, wick **416** shown in **FIGS. 4D, 4E and 4F**, or spray device **417** shown in **FIG. 4G**. The liquid fuel spreader (device) such as a sprayer or a wick can be the vaporizer, for example, located in the main conduit, or external to the main conduit but in fluid communication with it.

[0182] Any conventional or otherwise known pump device **418** for passing fluid through the passageways and conduits of a liquid fuel CPOX reformer, for example, introducing liquid fuel through fuel line **414** into main conduit **404** can be used. For example, a metering pump, rotary pump, impeller pump, diaphragm pump, peristaltic pump, positive displacement pump such as a gerotor, gear pump, piezoelectric pump, electrokinetic pump, electroosmotic pump, capillary pump, and the like, can be utilized for this purpose. As indicated above, the pressurized liquid fuel can be spread within a conduit by a wick or as a fine spray or otherwise in droplet form by any of such conventional or otherwise known spray devices as fuel injectors, pressurized nozzles, atomizers (including those of the ultrasonic type), nebulizers, and the like. A second heater unit and a fuel spreader device can function in unison to vaporize the liquid fuel introduced into the conduit and together constitute the principal components of the fuel vaporizer system of a reformer. In some embodiments, a pump or equivalent device can deliver the fuel on an intermittent or pulsed flow basis. In certain embodiments, a pump or equivalent device can deliver the fuel as a substantially continuous flow. In particular embodiments, a pump or equivalent device can make rapid adjustments in fuel flow rate in response to changing CPOX reformer operating requirements.

[0183] Although a reformer can use any source of heat for driving vaporization of the liquid fuel during the start-up mode of operation, for example, a heater of the electrical resistance type (as in the case of heaters **406** and **413**), especially where

vaporization of the fuel is made to take place outside main conduit **404**, the embodiment of liquid CPOX reformer illustrated in **FIGS. 4A, 4D and 4G** employs heater **413** to not only incrementally to raise the temperature of the initially heated ambient temperature air but to heat the liquid fuel prior to its introduction into main conduit **404** and to provide sufficient heat for vaporizing the fuel once it enters the conduit. This optional provision for heating liquid fuel prior to its introduction into conduit can make it possible to vaporize a given amount of liquid reformable fuel faster, or a greater amount of liquid fuel within a given time period, than the same vaporizer system operating upon reformable fuel which is at ambient temperature at the time it enters the conduit.

[0184] To provide for the heating of the liquid fuel before it enters main conduit **404** and as shown in the vaporizer system, or assembly, illustrated in **FIGS. 4A, 4D and 4G**, fuel line **414** traverses the wall of main conduit **404** with section **419** of the fuel line being extended in length to prolong the residence time of fuel flowing therein where the fuel line passes through, or is proximate to, second heating zone **412** of main conduit **404**. An extended fuel line section can assume a variety of configurations for this purpose, for example, a coiled or helical winding (as shown) or a series of lengthwise folds, disposed on or proximate to the exterior surface of a conduit corresponding to a second heating zone or any similar such configuration disposed within the interior of the conduit at or near the second heating zone. Regardless of its exact configuration and/or disposition, extended fuel line section **419** must be in effective heat transfer proximity to second heating zone **412** so as to receive an amount of heat sufficient to raise the temperature of the fuel therein to within some preset range of temperature. Thus, a portion of the thermal output of heater **413** within second heating zone **412** of main conduit **404**, in addition to further heating air flowing within this zone, will transfer to fuel, for example, diesel fuel, flowing within the distal section **419** of fuel line **414**, which distal section of fuel line **414** can be lengthened or extended as shown by reference numeral **419**, thereby raising its temperature to within the preset range. Whichever range of temperatures is chosen for the fuel within the fuel line, it should not exceed the boiling point of the

fuel (from 150 °C to 350 °C in the case of diesel) if vapor lock and consequent shut-down of reformer **400** are to be avoided.

[0185] Liquid fuel spreader **415** is disposed within main conduit **404** downstream from second heating zone **412** and associated heater **413** and upstream from first mixing zone **420**. Thermocouple **423** is disposed within main conduit **404** downstream from the vaporizer in order to monitor the temperature of the vaporized fuel-air mixture (e.g., CPOX reaction mixture) beginning to form therein.

[0186] As illustrated in **FIGS. 4D, 4E and 4F**, in one embodiment of a vaporizer system described herein, the terminal section of fuel line **414** within main conduit **404** ends in a perforated or multi-slotted liquid fuel outlet **424** which can be in approximate alignment with the center of the cross section of the conduit so that the heated air stream from second heating zone **412** tends to contact evenly liquid fuel spread out upon the surface of wick **416**. The body of a wick, which can be fit over a liquid fuel outlet, can be fabricated from any suitable heat-resistant material. Examples of such heat-resistant materials include metal, ceramic, high temperature polymer, and the like, and combinations thereof, such as a spirally wound sheet of interwoven metal or carbon fibers (for imparting structural strength) and ceramic fibers (for wicking action). A wicking or capillary action can draw up heated diesel fuel discharged through the fuel outlet. The heated diesel drawn up to and upon the surface of a wick thereupon can vaporize on contact with heated air flowing downstream from a second heating zone and begin to combine with the heated air to form initially a non-uniform gaseous fuel-air mixture, i.e., a non-uniform gaseous CPOX reaction mixture. This initial fuel-air mixture following passage through the first static mixture within first mixing zone **420** then merges with the remaining complement of heated air flowing from branch conduit **411** into merger zone **421** and from there the merged streams flow into the second static mixer within second mixing zone **422** from which there exits a more compositionally uniform gaseous CPOX reaction mixture.

[0187] As illustrated in **FIG. 4G**, in another embodiment of liquid fuel vaporizer system herein, fuel line **414** terminates in liquid fuel spray device **417**, which ejects a

fine spray of heated diesel fuel into main conduit **404** in the same direction of flow as the heated air stream. As in the case of fuel-wicking component **416** of the vaporizer system illustrated in **FIGS. 4D, 4E and 4F**, the spray droplets of heated diesel discharged into main conduit **404** from spray device **417** vaporize upon contact with the heated air stream flowing downstream from second heating zone **412**. In both vaporizer system embodiments, described herein, the vaporized diesel begins to mix with the heated air to provide the heated fuel-air stream for ultimate introduction into CPOX reactor units.

[0188] In the liquid fuel vaporizer systems described herein, there is no or little opportunity for the diesel to come into direct contact with a heated surface, for example, that of an electrical resistance heater element, that would pose a risk of raising the temperature of the diesel fuel to or above its flash point, to cause spattering of the fuel rather than its vaporization and/or cause pyrolysis of the fuel resulting in coke formation. Thus, in the vaporizer systems illustrated in **FIGS. 4D, 4E, 4F and 4G**, the temperature of the diesel fuel can be readily and reliably maintained at a level below its flash point and without significant incidences of spattering or coking.

[0189] Referring to **FIG. 4A**, following its passage through the second static mixer disposed within second mixing zone **422**, gaseous CPOX reaction mixture exits main conduit **404** through outlet **425** and enters gas distributor **427** of manifold **426**, which is configured to provide a more uniform distribution of the reaction mixture to, and within, tubular CPOX reactor units **408**. Such an arrangement or other arrangement within the present teachings can provide a distribution of gaseous CPOX reaction mixture where the difference in flow rate of the gaseous CPOX reaction mixture within any two CPOX reactor units is not greater than about 20 percent, for example, not greater than about 10 percent, or not greater than about 5 percent.

[0190] Returning to **FIG. 4A**, manifold **426** (an enlarged longitudinal cross section view of a portion of which is illustrated in **FIG. 4I** together with associated tubular CPOX reactor units **408**) includes manifold housing, or enclosure, **428** defining manifold chamber **429** within which heated gaseous CPOX reaction mixture

(gas) distributor **427** is connected to outlet **425** of main conduit **404**. Heated gaseous CPOX reaction mixture exiting main conduit **404** through outlet **425** enters gas distributor **427** thereafter passing outwardly through apertures (e.g., holes or slots) **430** located at the bottom or lower part of the gas distributor, the gas then flowing around the exterior surface of the distributor to its top or upper part and from there into inlets **431** of tubular CPOX reactor units **408**. The path of the gaseous CPOX reaction mixture as it passes through orifices **430** and into inlets **431** is shown in **FIG. 4B**.

[0191] To eliminate or lessen the possibility that the temperature within some region(s) and/or surface(s) of manifold chamber **429** will fall to or below the condensation temperature of the vaporized liquid reformable fuel of the gaseous CPOX reaction mixture present therein, electrical resistance heater **432** and thermocouple **433** can be disposed within manifold chamber **429**, for example, on one or more of its internal surfaces or embedded within one or more of its walls, to provide an active heater system for maintaining the temperature within the chamber above the fuel condensation temperature. In addition to an active heater system, for example, as described above, or as an alternative thereto, a passive heat transfer system comprising thermally conductive elements **434**, for example, fabricated from a good conductor of heat such as copper, thermally linking CPOX reaction zones **409** of tubular CPOX reactor units **408** with manifold chamber **429** can be arranged within reformer **400** to convey heat of exotherm from CPOX reaction zones **409** to regions and/or surfaces within manifold chamber **429** so as to maintain the temperature of the vaporized fuel therein above its condensation temperature.

[0192] In addition to their function of preventing or minimizing the occurrence of fuel condensation, such active and/or passive heating systems can serve to make the temperature of the gaseous CPOX reaction mixture more uniform as it is introduced into inlets of CPOX reactor units with consequent benefits for both reformer operation and control. Thus, for example, one or both manifold heating systems can be operated to provide a gaseous CPOX reaction mixture of consistently uniform temperature throughout a manifold chamber such that there will be not more than about a 10% difference, for example, not more than about a 5% difference, in the

temperature of gaseous CPOX reaction mixture entering any two tubular CPOX reactor units.

**[0193]** Some specific factors that can bear upon the optimization of the design of a manifold for accomplishing its function of promoting a more uniform distribution of gaseous CPOX reaction mixture to CPOX reactor units include the configuration of its housing, the volume of its chamber, and the dimensions of the gas distributor including the number, design and placement of its orifices. Such factors in turn depend on such reformer design and operational factors as the target flow rates of gaseous CPOX reaction mixture within a conduit, the number and arrangement of CPOX reactor units, the shape and dimensions of inlets of CPOX reactor units, and similar considerations. A manifold of optimal fuel-air distribution performance for a particular liquid fuel CPOX reformer in accordance with the present teachings can be readily constructed by those skilled in the art employing routine testing methods.

**[0194]** Where a CPOX reaction zone of a CPOX reactor unit is substantially coextensive with the length of the reactor unit, a manifold housing can be fabricated from a material that remains thermally and mechanically stable at the high temperatures that are typical of CPOX reforming. In these embodiments, various kinds of refractory materials, including refractory composites such as carbon fiber- and/or glass fiber-reinforced ceramics, are suitable for fabricating the manifold housing. Suitable materials of construction include dense ceramics such as various known types of alumina, recrystallized alumina, alumino-silicates, boron nitride, glass-ceramics, magnesium oxide, zirconium phosphate, and the like, metals such as nickel-chromium-based super alloys, Hastelloy super alloys, and the like. However, these and other refractory materials tend to be relatively high in cost and can also be challenging to work with, especially in the case of manufacturing articles with relatively complex configurations.

**[0195]** As shown in an enlarged, exemplary longitudinal cross section view of CPOX reactor unit **408** illustrated in **FIG. 4J**, gas-permeable wall **451** of CPOX reactor units **408** can be divided along its length into a first, or upstream, region **452**, starting at its fuel-air mixture inlet **431**, that is substantially devoid of CPOX catalyst,

and a second, or downstream, region **453**, starting at the end of first region **452** and ending at or proximate to product reformat effluent outlet **454** of the reactor unit, that contains a catalytically effective amount of CPOX catalyst **464**. During steady-state operation of CPOX reformer **400** of **FIG. 4A**, this embodiment of CPOX reactor unit largely confines hot CPOX reaction zones **409** to their second regions **453** leaving its essentially CPOX catalyst-free first region **452** to remain at a considerably lower temperature, for example, in the region of from ambient to up about 350 °C, particularly at the juncture of fuel-air mixture inlets **431** of CPOX reactor units **408** and manifold housing **428**.

[0196] The lower temperature of a CPOX catalyst-free wall section zone, which temperature is lower than the melting temperature of many thermoplastic resins and below the thermal degradation temperature of many thermoset resins, makes it practical and advantageous to utilize any of several families of thermoplastic and thermoset resins for the manufacture of a manifold housing. Specific types of thermoplastic and thermoset resins that can be used for the fabrication of a manifold housing include polyetherimide (PEI), polyaryletherketones (PAEKs) such as polyether ether ketone (PEEK), phenol-formaldehyde resins, and the like. These and other thermally stable resins, in addition to their relatively low material cost, have the added advantage of being readily formable into complex shapes employing low cost manufacturing procedures such as extrusion molding, vacuum molding, injection molding, reaction injection molding, rotational molding, and the like, and are therefore well suited for making manifold housings having relatively complex geometries.

[0197] Returning to **FIG. 4A**, from manifold **426**, heated gaseous CPOX reaction mixture enters inlets **431** of CPOX reactor units **408** and into CPOX reaction zones **409** where the reaction mixture undergoes a gaseous phase CPOX reaction to produce a hydrogen-rich, carbon monoxide-containing reformat. In the start-up mode, one or more igniter(s) **435** initiates CPOX. After CPOX becomes self-sustaining, for example, when the temperature of the reaction zone reaches from about 250 °C to about 1100 °C, the igniter(s) can be shut off as external ignition no longer is required to maintain the now self-sustaining CPOX reaction.

[0198] **FIGS. 4A-4C and 4H** illustrate an embodiment of the present teachings where two igniters **435** (one for each array) are used to initiate a CPOX reaction within CPOX reaction zones **409** of CPOX reactor units **408** in a chamber during the start-up mode of operation of reformer **400**. As shown, CPOX reactor units **408** are arranged in two separate 2x7 arrays with each array being disposed within chamber **436** flanking main conduit **404**. The perimeter of an array marks the boundary between open space **438** of chamber **436** and thermal insulation **410**. Exterior surfaces **437** of the walls of CPOX reactor units **408** corresponding to at least a portion of their CPOX reaction zones **409** are exposed within open space **438**. If a hydrogen barrier is present, the hydrogen barrier can be the exposed, exterior surface of a CPOX reactor unit. Igniters **435** of the electrical resistance type, for example, rated at from 10 to 80 watts or greater, are disposed at opposite ends of chamber **436** where then radiant heat-producing elements **439** are positioned in proximity to, but in physical isolation from, exterior surfaces **437** of CPOX reactor units **408**. Thermocouples **440** are disposed at the ends of chamber **436** opposite igniters **435** in order to monitor the temperature of CPOX reaction zones **409** and provide a reformer control input as described in connection with the control system illustrated in **FIG. 3A**. Operation of the igniters causes radiant heat to be transferred to, and through, the walls of one or more nearby CPOX reactor units whereby CPOX is initiated within the CPOX reaction zone of such reactor unit(s). The thermal radiation emitted from the CPOX reaction zone(s) of these nearby CPOX reactor units then can initiate CPOX within the reaction zones of the remaining CPOX reactor units within the array as illustrated by the wavy arrows in **FIG. 4C**.

[0199] The provision of a single, or two, or at most a few, igniter(s) that avoid direct contact with CPOX reactor units provides several advantages over a CPOX igniter system in which each CPOX reactor unit has its own physically attached or integrated igniter. While use of the latter ignition system is contemplated by the present teachings, identification of an inoperative igniter can be problematic and its removal and replacement without damage to the CPOX reactor unit of which it is a part and/or disturbance to other reactor units in the array can be difficult. Accordingly, a single (or a few) igniter(s) appropriately positioned within an array or

plurality of CPOX reactor units can permit easy and simple identification and extraction from CPOX reformer of a failed or defective igniter, and its replacement with an operative igniter.

[0200] As shown in **FIGS. 4C** and **4H**, where two igniters are used, each igniter to ignite a 2x7 array of CPOX reactor units, it can be advantageous to reverse the positions of igniter **435** and thermocouple **440** on one side of chamber **436** relative to the positions of igniter **435** and thermocouple **440** on the other side of the chamber, particularly where there can be significant thermal communication between the two chambers. Such an arrangement has been observed to result in a more rapid initiation of CPOX within the CPOX reaction zones of each separate array of CPOX reactor units. However, it should be understood that with the appropriately dimensioned and positioned CPOX reactor units within a chamber, a single igniter can be used to initiate CPOX within the CPOX reaction zones of the CPOX reactor units within the chamber.

[0201] In addition to processing liquid reformable fuels, liquid fuel reformer **400** illustrated in **FIG. 4A** includes components that enable it to co-process and/or alternately/sequentially process gaseous reformable fuels, a capability that optimizes fuel management where both types of reformable fuel are available, for example, but not necessarily at the same time. Moreover, this dual fuel processing capability is further advantageous in that it exploits the thermal profile within main conduit **404** during steady-state operation of the reformer by utilizing heat of exotherm resulting from the CPOX reaction to initiate CPOX of gaseous fuel within heat transfer zone **407**.

[0202] As shown in **FIG. 4A**, reformer **400** includes gaseous reformable fuel line **441** and gaseous fuel inlet **442** through which a gaseous fuel such as methane or natural gas is introduced into main conduit **404** at a location therein which is downstream from centrifugal blower system **402** and inlet **403** and upstream from first heating zone **405** and heat transfer zone **407**. The gaseous fuel combines with the previously introduced ambient temperature air with the resulting gaseous fuel-air

mixture then passing through first heating zone **405** and thereafter through heat transfer zone **407**.

[0203] As shown, gas-permeable CPOX catalyst-containing support **443**, for example, a close-fitting sleeve, insert, lining or coating provided as a porous refractory metal and/or ceramic material, is disposed within heat transfer zone **407** of main conduit **404** and extends for at least part of the length, or the full length, of heat transfer zone **407**. The fuel-air mixture, heated within first heating zone **405** during a start-up mode of operation to a temperature sufficient to initiate CPOX, or to a CPOX-initiating temperature within heat transfer zone **407** during a steady-state mode of operation, undergoes CPOX upon contact with CPOX catalyst-containing support **443** to provide a hydrogen-rich reformat.

[0204] If desired, a liquid fuel CPOX reformer can be operated solely or intermittently with gaseous reformable fuel, or concurrently with both vaporized liquid fuel and gaseous reformable fuel. In the case of concurrent conversion of both types of fuel, the gaseous fuel is the first to undergo CPOX, such being effected by a CPOX catalyst-containing support disposed within a heat transfer zone. The hydrogen-rich reformat from this gaseous fuel CPOX reaction then combines downstream with a vaporized liquid fuel-air mixture, the latter thereafter undergoing CPOX within the CPOX reaction zones of tubular CPOX reactor units as described herein to produce an additional quantity of hydrogen-rich reformat.

[0205] The provision of a CPOX catalyst-containing support within a heat transfer zone of a conduit allows CPOX reforming of gaseous fuel to proceed therein under the milder temperature conditions that are typical of the more efficient CPOX conversion of gaseous fuels (e.g., from about 600 °C to about 850 °C) in contrast to the higher temperature regimes of the less efficient CPOX conversion of liquid reformable fuels such as diesel (e.g., from about 650 °C to 1,100 °C). Conducting gaseous fuel CPOX reforming within a CPOX catalyst-containing support at the aforementioned lower temperatures has the considerable advantage of reducing the risk of cracking of the fuel and consequent coke formation on the surfaces of the (main) conduit and CPOX reactor units. Such events would be more likely to occur

and lead to CPOX reformer failure were the gaseous fuel to be added directly to the CPOX reactor units with or following the introduction of vaporized fuel-air mixtures therein. Therefore, in certain embodiments of CPOX reformers that possess dual fuel conversion capacity, transitioning from the sole processing of gaseous fuel and back again following a period of liquid reformable fuel CPOX conversion and/or co-processing mixtures of vaporized liquid reformable fuel and gaseous reformable fuel can be readily and smoothly accomplished without risk to the integrity of the CPOX reformer and its proper functioning.

[0206] Returning to FIG. 4I, enlarged manifold portion 450 of manifold 426 of reformer 400 illustrated in FIGS. 4A and 4B includes upper housing structure 455, lower housing structure 456, manifold chamber 429, gaseous CPOX reaction mixture (gas) distributor 427 and gas distributor outlets 430 in fluid communication, for example, gaseous flow communication, with inlets 431 of tubular CPOX reactor units 408. Inlet ends 457 of tubular CPOX reactor units 408 are firmly seated within cavities 458 formed within upper housing structure 455 and are engaged in gas-tight relationship therewith by O-ring gaskets 459. Heated gaseous CPOX reaction mixture flows through outlets 430 of gas distributor 427, through inlets 431 of tubular CPOX reactor units 408 and into CPOX reaction zones 409, where the gaseous CPOX reaction mixture undergoes gaseous phase CPOX conversion to a hydrogen-rich, carbon monoxide-containing effluent reformat exiting the reactor units at their outlet ends 460 through associated outlets 454. As shown, CPOX reactor units 408 are seated above thermally conductive element 434, which can be an orifice plate that includes orifices leading from the gas distributor to the inlets of the CPOX reactor units. The orifice plate can be physically the same structure as the manifold housing or can be a separate structure that is attached to or sealed to the manifold housing as shown. In the latter configuration, the orifice plate can act as the thermally conductive element, or “heat spreader,” to prevent condensation of vaporized liquid fuel before it exits the manifold chamber.

[0207] As further shown in FIGS. 4J and 4K, gas permeable wall 451 of each tubular CPOX reactor unit 408 includes an inner surface 461, an outer surface 462, an open gaseous flow passageway 463 enclosed by gas-permeable wall 451, a portion of

which constitutes CPOX reaction zone **409**, and a catalytically effective amount of CPOX catalyst **464** supported within and/or comprising the structure of at least the section of gas-permeable wall **451** corresponding to second region **453** and CPOX reaction zone **409**. As illustrated, to prevent or inhibit the loss of product hydrogen gas through gas-permeable wall **451**, a hydrogen barrier **465** is attached to outer surface **462** of gas-permeable wall **451**.

**[0208]** An open gaseous flow passageway can allow for the substantially unimpeded flow of gaseous CPOX reaction mixture and hydrogen-containing reformat there, a structural feature of CPOX reactor units of the present teachings that contributes to the low back pressure which is characteristic of the operation of liquid fuel CPOX reformers of the present teachings. In the operation of a liquid fuel CPOX reformer in accordance with the present teachings, back pressures of not more than about 3 inches of water (0.0075 bar), for example, not more than about 2 inches of water, or not more than about 1 inch of water, are readily achievable.

**[0209]** As previously mentioned herein, to prevent or inhibit the loss of hydrogen by diffusion through and beyond a gas-permeable wall that forms a CPOX reactor unit, in some embodiments of CPOX reactor units, a hydrogen barrier is associated with, for example, attached to or adhered to, an outer or external surface of the gas-permeable wall for at least that portion of the length of the CPOX reactor unit corresponding to its CPOX reaction zone. Materials capable of functioning as effective hydrogen barriers should be thermally stable at the high temperatures typical of CPOX reactions and should be sufficiently dense to prevent or deter permeation or diffusion of reformat gases, particularly hydrogen, therethrough.

**[0210]** A variety of ceramic materials (inclusive of glasses and glass-ceramics) and metals meeting these requirements are known and are therefore suitable for providing hydrogen barrier. Specific materials for hydrogen barrier include, for example, aluminum, nickel, molybdenum, tin, chromium, alumina, recrystallized alumina, aluminides, alumino-silicates, titania, titanium carbide, titanium nitride, boron nitride, magnesium oxide, chromium oxide, zirconium phosphate, ceria, zirconia, mulite and the like, admixtures thereof and layered combinations thereof.

[0211] Where the nature of the material constituting a hydrogen barrier permits, the hydrogen barrier can be applied to at least that portion of an outer surface of a CPOX reactor unit wall corresponding to the CPOX reaction zone as a pre-formed layer, foil, film or membrane. The hydrogen barrier can be bonded to the wall with a refractory adhesive. Alternatively, a hydrogen barrier can be formed on an outer surface by employing any suitable deposition method, for example, any of the conventional or otherwise known ceramic-coating and metal-coating techniques such as spray coating, powder coating, brush coating, dipping, casting, co-extrusion, metallizing, and the like, and any of their many variations. A suitable range of thickness for a hydrogen barrier will depend primarily on the hydrogen permeability characteristics of the selected barrier material and the gas permeability characteristics of the wall enclosing the CPOX reaction zone, such thickness being determined by those skilled in the art. For many barrier materials and reactor wall structures, the thickness of a hydrogen barrier can vary from about 2 microns to about 15 microns, for example, between about 5 microns to 12 microns.

[0212] In addition, a hydrogen barrier can be a pressurized fluid such as a pressurized gas associated with the external surface of a gas-permeable wall of a CPOX reactor unit, for example, at least the CPOX catalyst-containing wall section. With sufficient pressure, a pressurized fluid exterior to a CPOX reactor unit can create a barrier to prevent the loss of hydrogen through the gas-permeable wall that forms the CPOX reactor unit. Pressurized fluids typically are pressurized gases, such as inert gases (e.g., nitrogen) and/or air. The use of pressurized air as a hydrogen barrier has the additional advantage of oxygen diffusing from the exterior to the interior of the CPOX reactor unit, which diffused oxygen can adjust the O:C ratio of the gaseous CPOX reaction mixture about to and/or being reformed, particularly where such a hydrogen barrier is used and present around the CPOX reaction zone.

[0213] In certain embodiments, the CPOX reactor units can be located in an air-tight chamber but for their inlets and outlets thereby to permit pressurization of a fluid such as a gas in the environment exterior to the CPOX reactor units, which pressurized gas can create a hydrogen barrier associated with the external surfaces of the CPOX reactor units. In particular embodiments, because hydrogen is not

produced in a CPOX reactor unit until the CPOX reaction zone, only the CPOX reaction zones of the CPOX reactor units are enclosed in an air-tight chamber that is pressurized with a fluid such as air. In embodiments where the CPOX reaction zone does not extend to the outlet of the CPOX reactor units, the beginning of the CPOX reaction zone to the outlet can be enclosed in an air-tight chamber to permit a pressurized gas to be used as a hydrogen barrier. In some designs, a chamber as described herein can encompass a portion of the CPOX reaction zone while another form of a hydrogen barrier can be present encompassing the remainder of the CPOX reaction zone.

**[0214]** In the embodiments where a chamber is used, such as an air-tight chamber, a conduit in fluid communication with the interior of the chamber can be used to pressurize the chamber with a fluid. For example, a pressurized fluid or gas conduit can provide operable fluid communication between the interior of the (air-tight) chamber and a source of pressurized or compressed fluid, such as a container a compressed gas such as compressed air.

**[0215]** As those skilled in the art will readily recognize and appreciate, the cross sectional configuration, number and dimensions of CPOX reactor units and the distances of their separation from each other measured from their geometric centers, or centroids, will be made to depend on the operational and mechanical performance specifications for a particular liquid fuel CPOX reactor. In the case of a CPOX reactor unit of substantially uniform circular cross section, for example, CPOX reactor unit **408** illustrated in **FIGS. 4C, 4J and 4K**, the number of such CPOX reactor units, their length, their internal and external diameters (defining the thickness of their gas-permeable walls) and the location, length and thickness of hydrogen barriers attached to outer surfaces of the gas-permeable walls will be determined by, among other things, the hydrogen-producing capacity of the CPOX reformer, which in turn is a function of several factors including the type, amount (loading and distribution of CPOX catalyst within the gas-permeable walls), the characteristics of the porous structure of walls, characteristics influencing the gas-permeability of the walls, (and therefore affecting the CPOX reaction) such as pore volume (a function of pore size), the principal type of pore (mostly open, i.e., reticulated, or mostly closed,

i.e., non-reticulated), and pore shape (spherical or irregular), the volumetric flow rates of CPOX reaction mixture, CPOX temperature, back pressure, and the like.

[0216] The desired mechanical performance characteristics of a particular liquid fuel CPOX reformer will depend to a considerable extent on such factors as the thermal and mechanical properties of the material used for construction of the CPOX reactor units, the volume and morphology of the pores of the gas-permeable structure of the walls of the CPOX reactor units, the dimensions of the reactor units, particularly wall thickness, and related factors.

[0217] For a liquid fuel CPOX reformer to suitably function, the gas permeability property of the catalytically-active wall structure of a tubular CPOX reactor unit enclosing a gaseous phase CPOX reaction zone must be such as to allow the vaporized liquid reformable fuel, and in the case of diesel, its longer chain components such as the  $C_{12}$ - $C_{14}$  hydrocarbons, to freely enter and diffuse through such wall structure thereby making effective contact not only with surface CPOX catalyst but interior CPOX catalyst as well, if present. It should be noted that CPOX reactor unit wall structures having limited gas permeability for the vaporized reformable fuel can be mass transport limited so as to impede significantly CPOX conversion of the vaporized liquid reformable fuel to hydrogen-rich reformat. By contrast, catalytically-active reactor wall structures of suitable gas permeability promote CPOX conversion of the vaporized liquid reformable fuel and selectivity for hydrogen-rich reformates of desirable composition.

[0218] Guided by the present teachings and employing known and conventional testing procedures, those skilled in the art can readily construct CPOX reactor units having catalytically-active wall structures exhibiting optimal gas permeability properties for a particular liquid reformable fuel to be processed.

[0219] Materials from which the catalytically-active wall structure of a CPOX reaction zone of a tubular CPOX reactor unit can be fabricated are those that enable such wall structures to remain stable under the high temperatures and oxidative environments characteristic of CPOX reactions. Conventional and otherwise known refractory metals, refractory ceramics, and combinations thereof can be used for the

construction of the catalytically-active wall structure of a CPOX reaction zone. Some of these materials, for example, perovskites, also can possess catalytic activity for partial oxidation and therefore can be useful not only for the fabrication of the catalytically-active wall structure of a CPOX reaction zone but also can supply part or even all of the CPOX catalyst for such structure.

[0220] In some embodiments, at least the section of the wall of a CPOX reaction zone or including a CPOX catalyst of a CPOX reactor unit can be made of or can include a perovskite. For example, greater than about 20%, greater than about 30%, greater than about 40%, greater than about 50%, greater than about 60%, greater than about 70%, greater than about 80%, or greater than about 90% by weight of such wall section can be perovskite. Such a wall section can be made entirely of a perovskite, or the entire wall of a CPOX reactor unit can be made of a perovskite or can include the percentages of a perovskite described herein. The balance of the materials of the section of the wall at least corresponding to the CPOX reaction zone can include at least one component selected from metals, ceramics, refractory binders, and CPOX catalysts other than a perovskite.

[0221] The perovskite can be at least one member selected from  $\text{LaNiO}_3$ ,  $\text{LaCoO}_3$ ,  $\text{LaCrO}_3$ ,  $\text{LaFeO}_3$  and  $\text{LaMnO}_3$ . Perovskites can include lanthanum strontium manganite, lanthanum strontium ferrite, lanthanum strontium cobalt ferrite, lanthanum calcium manganite, lanthanum strontium chromite, lanthanum strontium gallate magnesite, and combinations thereof. When present as a catalyst, the perovskite can be  $\text{La}_{1-x}\text{Ce}_x\text{Fe}_2\text{O}_3$ ,  $\text{LaCr}_{1-y}\text{Ru}_y\text{O}_3$ ,  $\text{La}_{1-x}\text{Sr}_x\text{Al}_{1-y}\text{Ru}_y\text{O}_3$  and  $\text{La}_{1-x}\text{Sr}_x\text{Fe}_2\text{O}_3$ , including combinations thereof, where x and y are numbers ranging from 0.01 to 0.5. In addition, other appropriately transition metal-doped perovskites can be used in the practice of the present teachings.

[0222] Among the useful refractory metals are titanium, vanadium, chromium, zirconium, molybdenum, rhodium, tungsten, nickel, iron and the like, their combinations with each other and/or with other metals and/or metal alloys, and the like. Refractory ceramics are a class of materials for the construction of the catalytically-active wall structures due to their relatively low cost compared to many

refractory metals and metal alloys that are also useful for this purpose. The comparative ease with which such ceramics can be formed into tubular gas-permeable structures of fairly reproducible pore type employing known and conventional pore-forming procedures and the generally highly satisfactory structural/mechanical properties of ceramics (including coefficients of thermal expansion and thermal shock performance) and resistance to chemical degradation make them attractive materials. Suitable refractory ceramics for the construction of a CPOX reaction zone (which as previously stated, can include the entire wall structure of a CPOX reactor unit) include, for example, perovskites, spinels, magnesia, ceria, stabilized ceria, silica, titania, zirconia, stabilized zirconia such as alumina-stabilized zirconia, calcia-stabilized zirconia, ceria-stabilized zirconia, magnesia-stabilized zirconia, lanthana-stabilized zirconia and yttria-stabilized zirconia, zirconia stabilized alumina, pyrochlores, brownmillerites, zirconium phosphate, silicon carbide, yttrium aluminum garnet, alumina, alpha-alumina, gamma-alumina, beta-alumina, aluminum silicate, cordierite,  $\text{MgAl}_2\text{O}_4$ , and the like, various ones of which are disclosed in U.S. Patent Nos. 6,402,989 and 7,070,752, the entire contents of which are incorporated by reference herein; and, rare earth aluminates and rare earth gallates various ones of which are disclosed in U.S. Patent Nos. 7,001,867 and 7,888,278, the entire contents of which are incorporated by reference herein.

**[0223]** In general, the total or overall fuel conversion capacity of a CPOX reformer of a given design will be the sum of the fuel conversion capabilities of its individual CPOX reactor units. The minimum distance between adjacent CPOX reactor units will be such that in the steady-state mode of operation of the reformer, the temperature of the reactor units does not exceed a predetermined, or preset, maximum, and the maximum distance between adjacent CPOX reactor units is that distance beyond which the CPOX reaction fails to be initiated within one or more reactor units during a start-up mode of operation of the liquid fuel CPOX reformer or the temperature within one or more CPOX reactor units falls below a predetermined, or preset, minimum intended for the steady-state mode of operation of the reformer. The minimum and maximum distances between adjacent CPOX reactor units readily

can be determined for a given reformer section design employing routine testing methods.

**[0224]** The present teachings contemplate the use of any of the heretofore known and conventional CPOX catalysts (including catalyst systems), methods of incorporating catalyst within a porous substrate or support, specifically, a gas-permeable wall of the a CPOX reactor unit, and patterns of catalyst distribution including, but not limited to, catalyst confined to a particular section of a wall, catalyst loading increased along the length of a reactor unit and/or decreased from an inner surface of a wall to its outer surface, CPOX catalyst that varies in composition along the length of the reactor unit, and similar variants. Thus, for example, increasing catalyst loading within a wall of a CPOX reactor unit from the start of a CPOX reaction zone to, or near, the end thereof can be helpful in maintaining a constant CPOX reaction temperature with this zone.

**[0225]** Among the many known and conventional CPOX catalysts that can be utilized herein are the metals, metal alloys, metal oxides, mixed metal oxides, perovskites, pyrochlores, their mixtures and combinations, including various ones of which are disclosed, for example, in U.S. Patent Nos. 5,149,156; 5,447,705; 6,379,586; 6,402,989; 6,458,334; 6,488,907; 6,702,960; 6,726,853; 6,878,667; 7,070,752; 7,090,826; 7,328,691; 7,585,810; 7,888,278; 8,062,800; and, 8,241,600, the entire contents of which are incorporated by reference herein.

**[0226]** While numerous highly active noble metal-containing CPOX catalysts are known and as such can be useful herein, they are generally less used than other known types of CPOX catalysts due to their high cost, their tendency to sinter at high temperatures and consequently undergo a reduction in catalytic activity, and their proneness to poisoning by sulfur.

**[0227]** Perovskite catalysts are a class of CPOX catalyst useful in the present teachings as they are also suitable for the construction of the catalytically-active wall structures of a CPOX reactor unit. Perovskite catalysts are characterized by the structure  $ABX_3$  where "A" and "B" are cations of very different sizes and "X" is an

anion, generally oxygen, that bonds to both cations. Examples of suitable perovskite CPOX catalysts include  $\text{LaNiO}_3$ ,  $\text{LaCoO}_3$ ,  $\text{LaCrO}_3$ ,  $\text{LaFeO}_3$  and  $\text{LaMnO}_3$ .

[0228] A-site modification of the perovskites generally affects their thermal stability while B-site modification generally affects their catalytic activity. Perovskites can be tailor-modified for particular CPOX reaction conditions by doping at their A and/or B sites. Doping results in the atomic level dispersion of the active dopant within the perovskite lattice thereby inhibiting degradations in their catalytic performance. Perovskites also can exhibit excellent tolerance to sulfur at high temperatures characteristic of CPOX reforming. Examples of doped perovskites useful as CPOX catalysts include  $\text{La}_{1-x}\text{Ce}_x\text{FeO}_3$ ,  $\text{LaCr}_{1-y}\text{Ru}_y\text{O}_3$ ,  $\text{La}_{1-x}\text{Sr}_x\text{Al}_{1-y}\text{Ru}_y\text{O}_3$  and  $\text{La}_{1-x}\text{Sr}_x\text{FeO}_3$  wherein x and y are numbers from 0.05 to 0.5, for example, from 0.05 to 0.2, depending on the solubility limit and cost of the dopants.

[0229] As previously discussed in connection with **FIG. 4J**, a CPOX reactor unit can include a first, upstream region that is substantially devoid of CPOX catalyst and can extend from its inlet end to a second, downstream region that contains a CPOX catalyst. The second, downstream region typically extends from the end of the first region to its reformat effluent outlet, although the amount of catalyst near the outlet can decline. The length of these regions relative to the entire length of the CPOX reactor unit can vary considerably. Thus, for example, a first region can extend from about 20% to about 60%, for example, from about 30% to about 40% or about 50%, of the length of a CPOX reactor unit, with a second region extending the remainder of the length of the CPOX reactor unit. As explained in connection with the description of CPOX reformer 400 of **FIG. 4A**, during steady-state operation of CPOX reactor unit 400, first region 452 remains at a considerably lower temperature than second region 453 (corresponding to CPOX reaction zone 409) allowing manifold housing 428 of manifold 426 of **FIG. 4A** to be fabricated from any of numerous kinds of low cost, readily moldable thermoplastic or thermoset resins.

[0230] CPOX reactor unit 408, in addition to the circular cross section shown in **FIG. 4K**, can assume other cross sectional configurations such as those illustrated in **FIGS. 4L** and **4M**. **FIG. 4L** illustrates a CPOX reactor unit having an alternating

concave-convex, or bilobate, cross section. CPOX reactor units having such a cross sectional configuration can be especially advantageous where their outlet sections are to be joined to, or mated with, similarly configured tubular solid oxide fuel cell (SOFC) units as in the SOFC fuel cell assembly of co-pending, commonly assigned U.S. Patent Application Publication No. 2013/0230787, by Finnerty et al., the entire contents of which are incorporated by reference herein for all purposes.

[0231] Alternatively or in combination with direct connection of a CPOX reactor unit to a tubular fuel cell unit, the outlets of two or more CPOX reactor units of a multi-tubular CPOX reformer can be in fluid communication with each other (and with additional outlets of CPOX reactor units) and the hydrogen-rich reformat from the outlets can be combined prior to introduction into a fuel cell. For example, the hydrogen-rich reformat effluent from two or more CPOX reactor units can be combined in a manifold or similar device and/or one or more conduits and then introduced into a fuel cell, which could be a multi-tubular fuel cell or a single fuel cell unit. Accordingly, a CPOX reformer of the present teachings can be adapted to various applications depending on its end use, for example, providing hydrogen-rich reformat to a single or multi-tubular fuel cell unit.

[0232] Centrifugal blower system 402 of CPOX reformer 400, shown in greater detail in FIGS. 4N and 4O, disclosed in co-pending, commonly assigned U.S. Patent Application Publication No. 2012/0328969, by DeWald et al., the entire contents of which are incorporated by reference herein for all purposes. Among its other advantages, a centrifugal blower system can possess the ability to make rapid adjustments in the volume of air introduced into a conduit and/or in the rate of flow of the gaseous fuel-air mixture to CPOX reactor units in response to changes in the demand for product hydrogen-rich reformat that single centrifugal blowers of comparable air flow capacity are incapable of providing, as explained herein, without resorting to blowers of relatively high power consumption.

[0233] Single centrifugal blowers such as those utilized to provide gas flows for the operation of known and conventional reformers require suitable control of the full range of motor revolutions per minute (rpm) in order to meet fluctuating gas flow

demands. Depending on the target gas flow requirements for a particular mode of operation of a CPOX reformer, optimum performance of a single blower for meeting these requirement can involve employing a blower having an impeller of relatively small size driven at relatively high rpm, for example, about 20,000 rpm and above, or a blower having an impeller of relatively large size driven at relatively low rpm, for example, below about 20,000 rpm and more commonly, below about 10,000 rpm. The first arrangement, i.e., a single blower having a relatively small impeller driven at relatively high rpm, requires a more powerful and specialized motor which of necessity will draw a correspondingly greater amount of electrical power for its operation. The second arrangement, i.e., a single blower having a relatively large impeller driven at relatively low rpm, can make control and fine tuning of the blower output more difficult due to the greater inertia of a large impeller.

[0234] To prevent overshooting of the target pressure and gas flow requirements for a liquid fuel CPOX reformer, a single blower having a relatively high inertia impeller must be overdamped when tuning the blower for its expected range of gas pressure and flow capacity. The effect of this overdamping to compensate for the relatively high inertia of the impeller is to cause the blower to be slow in responding to changing, and often rapidly changing, gas flow requirements. This characteristically slow response of a single centrifugal blower having a relatively high inertia impeller can require a more complicated control system for satisfactorily responding to fluctuations in gas flow demand.

[0235] Utilizing a centrifugal blower system to drive gas flows within a CPOX reformer can enable the system to benefit from both low inertia impellers for control as well as low drive motor rpm and power draw to meet quickly target gas flow and pressure requirements. Controlling one or more blower units in an interconnected series of blowers such as a centrifugal blower system to provide a major portion of the target gas pressure and gas flow, for example, about 60% to about 90% of the target gas pressure and gas flow, can enable the remainder of the target gas pressure and gas flow to be provided by one or more other blower units in the system. The result of splitting the task of providing target gas flows and pressures to a CPOX reformer between at least two integrated, i.e., interconnected, centrifugal blowers as

in a dual centrifugal blower system results in such flows and pressures being reached in less time and with greater accuracy than is possible with a single centrifugal blower unit. Additionally, the power draw and noise level can be low in a centrifugal blower system because the blower impellers do not require high rpm for their operation.

[0236] As shown in **FIGS. 4N** and **4O**, centrifugal blower system **402** includes first centrifugal blower unit **486** connected to second centrifugal blower unit **487** through duct **488**. First blower unit **486** includes casing **489** having axial inlet **490** and radial outlet **491**, impeller **492** disposed within casing **489** for drawing ambient air at a first pressure into axial inlet **490** and expelling air at a second higher pressure through radial outlet **491**, and electric motor **493** for driving impeller **492**. Second blower unit **487** includes casing **494** and, as shown by the cutaway section of duct **488** in **FIG. 4N**, impeller **495** disposed within casing **494** and driven by electrical motor **496**, and axial inlet **497** for receiving gas discharged from outlet **491** of first blower unit **486**. The second blower unit **487** further includes radial outlet **498** and outlet gas stream housing **499**, the discharge end **484** of which can be connected to one end of a conduit, for example, main conduit **404** of liquid fuel CPOX reformer **400** of **FIG. 4A**, as indicated by the dotted lines.

[0237] The arrows in **FIGS. 4N** and **4O** indicate the general direction of the ambient air through the radial outlet of each blower unit in the series of blowers constituting centrifugal blower system **402**. As shown, for example, in **FIG. 4N**, the trajectory of the ambient air stream expelled through outlet **491** of first blower unit **486** and the trajectory of the ambient air stream expelled through outlet **498** of second blower unit **487** are not parallel to their respective outlets but are at some angle thereto. By arranging the geometry of duct **488** to receive the ambient air stream discharged through outlet **491** in such a manner that the stream remains approximately parallel to the interior walls of the duct, it can be possible to prevent or reduce the turbulence that would otherwise occur were the stream to impinge upon these walls. Turbulence can be advantageously minimized or avoided so as to reduce or eliminate it as a source of back pressure in a centrifugal blower system. For this same reason, it can be advantageous to arrange the angle of gas stream housing **499** so that its interior walls will be approximately parallel to the trajectory of the ambient

air discharged through outlet **498** of second blower unit **487**. The optimum geometry of the interior walls of a duct relative to the trajectory of its gas stream and the angle of offset of a gas stream housing can be readily determined for a given centrifugal blower system employing routine experimentation. In centrifugal blower system **402**, interior, or guiding, surfaces of duct **488** and interior, or guiding, surfaces of gas stream housing **499** can be pitched at an angle  $\alpha$  of from about  $12^\circ$  to about  $20^\circ$ , for example, from about  $14^\circ$  to about  $18^\circ$ , relative to outlets **491** and **498**.

**[0238]** Liquid fuel CPOX reformers **500** of **FIG. 5A**, **550** of **FIG. 5B**, **600** of **FIG. 6A** and **650** of **FIG. 6B** include most of the elements and features of, and operate in essentially the same way as, liquid fuel CPOX reformer **400** of **FIGS. 4A-4H** and therefore will be described only in respect of significant differences from liquid fuel CPOX reformer **400**.

**[0239]** To that end, CPOX reformers **500** and **550** of **FIGS. 5A** and **5B**, respectively, differ primarily in the manner in which the air component and/or liquid reformable fuel component of the gaseous CPOX reaction mixture are heated during the steady-state mode of operation of the reformer. In CPOX reformers **500** and **550**, a pressurized flow of ambient temperature air is introduced into, and passes through, heat exchangers **501** and **551**, respectively, through which is circulated a flow of heat exchange fluid, for example, hot combustion gases from an external heat-producing source such as a fuel cell stack (not shown). This arrangement differs from the provision for heating air in CPOX reformer **400** in which ambient air entering the reformer during the steady-state mode of operation of the reformer passes through heat transfer zone **407** of main conduit **404**, the air being heated within zone **407** by heat recovered from the exotherm of the CPOX reaction occurring within CPOX reaction zones **409** of CPOX reactor units **408**. In addition, in contrast to the fuel heating system shown in **FIG. 4D** in which fuel flowing within fuel line section **414** is heated by heater **413**, in CPOX reformers **500** and **550**, a section of fuel line can be routed through heat exchangers **501** and **551**, respectively, to similarly provide heating of the fuel prior to its vaporization. In all other respects, CPOX reformers **500** and **550** can operate in essentially the same way as CPOX reformer **400**. Instead of, or in addition to, heating air prior to its introduction into main conduit **404**, liquid

reformable fuel at ambient temperature can be routed through heat exchangers **501** and **551**, respectively, the resulting heated fuel thereafter being vaporized externally to main conduit **404** or, as in operation of the liquid fuel vaporizers illustrated in **FIGS. 4D-4G**, within main conduit **404**.

[0240] Compared to gaseous reformable fuels such as methane, propane, butane, natural gas, petroleum gas, and the like, liquid fuels such as diesel, jet fuel and other distillates are less efficient sources of product reformat, generally undergoing CPOX with greater exothermicity. Means for cooling a CPOX reactor unit of a liquid fuel CPOX reformer of the present teachings, while optional, can be useful in providing further thermal management and control of the liquid fuel CPOX reformer. To provide such further degree of reformer control, CPOX reformers **600** and **650** of, respectively, **FIGS. 6A** and **6B**, include heat exchangers for cooling their CPOX reactor units to within a preset range of temperature, for example, from about 750° to about 950°C.

[0241] As shown in **FIG. 6A**, CPOX reformer **600** includes centrifugal blower **601** for directing a coolant stream, for example, air at ambient temperature, against the exposed exterior surfaces of lower sections **602** of CPOX reactor units **603**. In place of a centrifugal blower, any other suitable device for providing a coolant stream can be utilized, for example, a fan, an impeller, and the like.

[0242] In CPOX reformer **650** of **FIGS. 6B** and **6C**, a heat conducting assembly includes variously configured and arranged heat-conducting members **651** and **654**. Heat-conducting members can be provided, for example, as rods, plates, tubes, and the like, fabricated from materials having suitably high thermal conductivity, for example, metals (particularly copper and copper alloys), carbons, ceramics and composites, and the like. Heat-conducting members can conduct radiant heat, for example, heat radiated from the exposed exterior surfaces of CPOX reactor units **652** within chamber **653** to heat-conducting member **654**, likewise fabricated from a material exhibiting high thermal conductivity such as copper, terminating in heat-radiative member **655**, for example, the series of fins shown. Centrifugal blower unit

**656** directs a coolant stream, for example, air at ambient temperature, against multiple fin-bearing heat-radiative member **655** to dissipate its heat.

[0243] Chamber **653** shown in **FIGS. 6B** and **6C** can contain a pressurized fluid such as a pressurized gas that can act as a hydrogen barrier as discussed herein. Chamber **653** can be an air-tight chamber. As depicted, chamber **653** is generally located to include in the chamber the CPOX reaction zone (e.g., the section of the gas permeable wall including a CPOX catalyst) of each of the CPOX reactor units **652** as well as to include the main conduit, igniters and thermocouples (not labeled). As shown, although the chamber includes most of the CPOX reaction zone, one or more walls of the chamber can act as a hydrogen barrier where the CPOX reactor units traverse or extend through the walls, for example, above and below the interior of the chamber as shown. A pressurized fluid conduit such as a pressurized gas conduit (not shown) can provide operable fluid communication between the interior of the chamber and a source of pressurized or compressed fluid such as compressed air. The pressurization of the chamber can be controlled using the appropriate valve and pressure sensor assemblies to provide sufficient fluid pressure for an adequate hydrogen barrier.

[0244] **FIG. 7** presents graphical data demonstrating the relationship between the oxygen (O) to carbon (C) molar ratio of vaporized diesel fuel-air CPOX reaction mixtures and CPOX reaction temperature. As the data show, as the O to C molar ratio of the CPOX reaction mixture is gradually reduced, i.e., as the reaction mixture is adjusted from a relatively carbon-lean one to a relatively carbon-rich one, CPOX reaction temperature declines. These data hold several implications for optimized operations of a liquid fuel CPOX reformer in accordance with the present teachings.

[0245] To promote rapid heating of CPOX catalyst and, consequently, the onset of the gaseous phase CPOX reaction, gaseous CPOX reaction mixtures having higher O to C molar ratios (i.e., fuel-lean reaction mixtures) can be utilized during the start-up mode of operation of the reformer. The higher operating temperatures associated with fuel-lean CPOX reaction mixtures can facilitate a more rapid increase in CPOX catalyst temperature and reduced time to steady-state operation. Additionally, a

fuel-lean ratio tends to help inhibit coke formation before the CPOX catalyst has attained its optimum temperature and become fully activated. Once the CPOX catalyst has reached a temperature of about 650 °C and above, the O to C molar ratio can be reduced as fuel flow is increased. Reducing the O to C molar ratio lowers the catalyst temperature and can enable more fuel to be processed without losing thermal control of the CPOX reactor units and in turn, the fuel vaporizer unit. The opposite action can be taken for the shut-down operation, i.e., fuel flow is reduced at a maintained O to C molar ratio. As the temperature of the CPOX reaction zones of the CPOX reactor units begin to approach or fall below a temperature resulting in coke formation, for example, below about 650 °C, the O to C molar ratio can be increased to prevent or minimize coking as the CPOX catalyst deactivates. Typically, the CPOX reformer can be shut down when the temperature of the CPOX reaction mixture falls below about 500 °C. The flow of oxygen-containing gas can be continued for up to about 15 to 20 seconds or so after fuel flow has been discontinued. Such a shut-down procedure can allow for vaporization and removal of fuel from the reformer that can be contained within a conduit or a section of fuel line between a fuel control valve and locus of introduction of the fuel into the conduit. This control characteristic can be influenced by various reformer components including the particular vaporizer system and controller unit components utilized in a specific reformer design.

**[0246]** The O to C molar ratio of the fuel-air CPOX reaction mixture can be controlled during the operation to tailor its output thermal conditions, with the understanding that changing the O to C molar ratio can result in changes to the quality and/or composition of the reformat. There is a range of O to C molar ratio that shifts from fuel-lean to fuel-rich as CPOX temperature increases above about 650 °C. Different CPOX catalysts can affect the operational windows and CPOX temperatures. Additionally, different fuels (gaseous or liquid) can change the CPOX temperatures depending upon the efficiency of the reforming reactions.

**[0247]** Those skilled in the art, taking into account the various embodiments of the liquid fuel CPOX reformers described herein and the principles of operation of the same, by employing routine experimental procedures can readily optimize the

design of a particular CPOX reformer of desired liquid reformable fuel conversion capacity, structural characteristics, and mechanical properties in accordance with the present teachings.

**[0248]** The present teachings encompass embodiments in other specific forms without departing from the spirit or essential characteristics thereof. The foregoing embodiments are therefore to be considered in all respects illustrative rather than limiting on the present teachings described herein. Scope of the present invention is thus indicated by the appended claims rather than by the foregoing description, and all changes that come within the meaning and range of equivalency of the claims are intended to be embraced therein.

**CLAIMS**

1. A liquid fuel CPOX reformer comprising:
  - an array of spaced-apart CPOX reactor units, each CPOX reactor unit comprising an elongate tube having a gas-permeable wall with an internal surface and an external surface, the gas-permeable wall enclosing an open gaseous flow passageway and defining an inlet and an outlet of the CPOX reactor unit,
  - wherein a CPOX reactor unit is in thermal communication with at least the adjacent CPOX reactor unit(s) in the array,
  - at least a section of the gas-permeable wall comprises a CPOX catalyst,
  - and
  - a hydrogen barrier associated with the external surface of at least the CPOX catalyst-containing wall section of a CPOX reactor unit;
  - a vaporizer in fluid communication with inlets of the CPOX reactor units; and
  - an igniter in thermal communication with at least a section of the gas permeable wall comprising a CPOX catalyst of at least one CPOX reactor unit.
2. The liquid fuel CPOX reformer of claim 1, wherein the maximum distance between adjacent CPOX reactor units is that distance beyond which a CPOX reaction fails to be initiated in an adjacent CPOX reactor unit by the heat from a CPOX reaction in an operating CPOX reactor unit and/or during a steady-state mode of operation, the temperature of the array of spaced-apart CPOX reactor units falls below a predetermined minimum array temperature; and the minimum distance between adjacent CPOX reactor units is that distance below which the temperature at an outlet of a CPOX reactor unit is greater than a predetermined maximum temperature.
3. The liquid fuel CPOX reformer of claim 2, wherein the predetermined maximum temperature is a temperature that is tolerable by an inlet of a fuel cell stack in thermal and fluid communication with an outlet of a CPOX reactor unit.
4. The liquid fuel CPOX reformer of claim 2 or 3, wherein the predetermined maximum temperature is about 900 °C.

5. The liquid fuel CPOX reformer of any one of claims 2-4, wherein the predetermined minimum array temperature is about 600 °C.
6. The liquid fuel CPOX reformer of any one of claims 1-5, comprising a source of liquid reformable fuel in fluid communication with the vaporizer.
7. The liquid fuel CPOX reformer of any one of claims 1-6, comprising more than one igniter, wherein each igniter is positioned in thermal communication with at least a section of the gas-permeable wall comprising a CPOX catalyst of at least one CPOX reactor unit.
8. The liquid fuel CPOX reformer of any one of claims 1-7, wherein the CPOX catalyst is disposed within the wall of the CPOX reactor unit, disposed on an internal surface of the wall of the CPOX reactor unit, partially or completely forms the structure of the wall of the CPOX reactor unit, and combinations thereof.
9. The liquid fuel CPOX reformer of any one of claims 1-8, wherein the hydrogen barrier comprises pressurized air.
10. The liquid fuel CPOX reformer of any one of claims 1-9, comprising a source of oxygen-containing gas, wherein the source of oxygen-containing gas is in fluid communication with the vaporizer and in fluid communication with a mixing zone downstream of the vaporizer.
11. The liquid fuel CPOX reformer of claim 10, comprising a first source of oxygen-containing gas in fluid communication with the vaporizer and a second source of oxygen-containing gas in fluid communication with a mixing zone downstream of the vaporizer.
12. The liquid fuel CPOX reformer of any one of claims 1-11, comprising an oxygen-containing gas conduit having a branch conduit, the oxygen-containing gas conduit providing fluid communication between a source of oxygen-containing gas and the vaporizer and the branch conduit providing fluid communication between the source of oxygen-containing gas and a mixing zone downstream of the vaporizer, wherein the oxygen-containing gas conduit and the branch conduit divide the delivery of an oxygen-

containing gas from the source of oxygen-containing gas to the vaporizer and the mixing zone downstream of the vaporizer.

13. The liquid fuel CPOX reformer of any one of claims 1-12, comprising:

a conduit comprising an oxygen-containing gas inlet and a gaseous CPOX reaction mixture outlet located downstream from an outlet of the vaporizer, wherein the conduit provides fluid communication between the oxygen-containing gas inlet and the gaseous CPOX reaction mixture outlet, and the gaseous CPOX reaction mixture outlet is in fluid communication with the inlets of the CPOX reactor units;

a first source of heat comprising an electric heater, the first source of heat being disposed in the conduit at a location downstream from the oxygen-containing gas inlet and upstream from the outlet of the vaporizer; and

a second source of heat comprising heat of exotherm from the liquid fuel CPOX reformer and/or a hydrogen reformat-consuming device external to the liquid fuel reformer, the second source of heat in thermal communication with the conduit and at a location downstream from the first source of heat and upstream from or coincident with the outlet of the vaporizer;

wherein the outlet of the vaporizer is in fluid communication with the conduit.

14. The liquid fuel CPOX reformer of claim 13, wherein the vaporizer is disposed in the conduit.

15. The liquid fuel CPOX reformer of claim 13 or 14, comprising a third source of heat, the third source of heat comprising an electric heater and being disposed in the conduit at a location downstream from the first source of heat and upstream from the outlet of the vaporizer.

16. The liquid fuel CPOX reformer of claim 13 or 14, comprising a thermally-regulating assembly, the thermally-regulating assembly comprising a heater and a cooler, the heater and/or the cooler being disposed in the conduit and/or in thermal communication with the conduit at a location downstream from the first source of heat and upstream from the outlet of the vaporizer.

17. The liquid fuel CPOX reformer of any one of claims 13-16, wherein the conduit comprises an inlet for gaseous reformable fuel, and a CPOX catalyst-containing section downstream from the gaseous reformable fuel inlet and the oxygen-containing gas inlet and upstream from the outlet of the vaporizer.

18. The liquid fuel CPOX reformer of any one of claims 13-17, wherein the vaporizer comprises a liquid reformable fuel inlet, and the liquid fuel CPOX reformer comprises a controller, the controller in operable communication with a thermocouple located in the conduit at or downstream from the outlet of the vaporizer, a thermocouple located in the conduit upstream of the outlet of the vaporizer, an oxygen-containing gas flow meter located in the conduit upstream of the vaporizer, a liquid reformable fuel flow meter located at or upstream of the vaporizer and in fluid communication with a source of liquid reformable fuel, a source of oxygen-containing gas, a source of liquid reformable fuel, the first source of heat, the second source of heat, and the third source of heat and/or thermally-regulating assembly, when present.

19. The liquid fuel CPOX reformer of any one of claims 1-18, wherein the vaporizer comprises or is a fuel spreader.

20. A method of CPOX reforming a liquid reformable fuel to a hydrogen-rich reformate, the method comprising:

introducing a gaseous CPOX reaction mixture comprising a vaporized liquid reformable fuel into inlets of CPOX reactor units, wherein the CPOX reactor units form an array of spaced-apart CPOX reactor units, each CPOX reactor unit comprising an elongate tube having a wall with an internal surface and an external surface, the wall enclosing an open gaseous flow passageway and defining an inlet and an outlet of the CPOX reactor unit,

wherein a CPOX reactor unit is in thermal communication with at least the adjacent CPOX reactor unit(s) in the array,

at least a section of the wall comprises a CPOX catalyst,

the CPOX catalyst-containing wall section is gas-permeable to allow gaseous CPOX reaction mixture to diffuse therein and product hydrogen-rich reformat to diffuse therefrom;; and

a hydrogen barrier associated with the external surface of at least the CPOX catalyst-containing wall section of a CPOX reactor unit;

initiating catalytic partial oxidation of the gaseous CPOX reaction mixture to begin production of a hydrogen-rich reformat in at least one CPOX reactor unit; and

maintaining catalytic partial oxidation of the gaseous CPOX reaction mixture in the CPOX reactor unit.

21. The method of claim 20, wherein the maximum distance between adjacent CPOX reactor units is that distance beyond which a CPOX reaction fails to be initiated in an adjacent CPOX reactor unit by the heat from a CPOX reaction in an operating CPOX reactor unit and/or during a steady-state mode of operation, the temperature of a CPOX reactor unit falls below a predetermined minimum array temperature; and the minimum distance between adjacent CPOX reactor units is that distance below which the temperature at an outlet of a CPOX reactor unit is greater than a predetermined maximum temperature.

22. The method of claim 20 or 21, wherein initiating catalytic partial oxidation comprises:

initiating a CPOX reaction in one CPOX reactor unit;

transferring the heat from the CPOX reaction to an adjacent CPOX reactor unit to initiate a CPOX reaction therein; and

repeating transferring the heat to initiate a CPOX reaction in each of the CPOX reactors of the array.

23. The method of any one of claims 20-22, wherein initiating catalytic partial oxidation comprises initiating more than a single igniter to initiate catalytic partial oxidation of the gaseous CPOX reaction mixture in each of the CPOX reactor units.

24. The method of any one of claims 20-23, wherein maintaining catalytic partial oxidation of the gaseous CPOX reaction mixture comprises transferring heat among the CPOX reactor units to maintain a predetermined minimum array temperature.

25. The method of claim 24, wherein the predetermined minimum array temperature is substantially uniform across the array of CPOX reactor units.

26. The method of any one of claims 20-25, comprising:  
mixing an oxygen-containing gas and a vaporized liquid reformable fuel to provide a gaseous CPOX reaction mixture having an oxygen (O):carbon (C) ratio; and  
mixing additional oxygen-containing gas with the gaseous CPOX reaction mixture to increase the O:C ratio of the gaseous CPOX reaction mixture prior to introducing the gaseous CPOX reaction mixture having an increased O:C ratio into the inlets of the CPOX reactor units.

27. The method of claim 26, wherein mixing an oxygen-containing gas and a vaporized liquid reformable fuel occurs in, coincident with or downstream from a vaporizer, and the amount of heat required to heat the vaporizer to its operating temperature is less than the amount of heat required in the absence of the step of mixing additional oxygen-containing gas with the gaseous CPOX reaction mixture, and the method provides a gaseous CPOX reaction mixture having the increased O:C ratio to the inlets of the CPOX reactor units.

28. The method of any one of claims 20-27, wherein introducing a gaseous CPOX reaction mixture comprises:  
introducing an oxygen-containing gas into a conduit for routing fluids toward the inlet of a CPOX reformer unit;  
heating a stream of the oxygen-containing gas with a first source of heat comprising an electric heater disposed in the conduit to provide a stream of heated oxygen-containing gas; and  
introducing a liquid reformable fuel into the stream of heated oxygen-containing gas in, through, at or past a vaporizer to provide the gaseous CPOX reaction mixture.

29. The method of claim 28, comprising:

heating the stream of the oxygen-containing gas and/or the stream of heated oxygen-containing gas with a second source of heat, the second source of heat in thermal communication with the conduit and comprising heat of exotherm from the CPOX reactor units and/or a hydrogen reformat-consuming device external to the CPOX reactor units.

30. The method of claim 28 or 29, comprising:

heating and/or cooling upstream of the outlet of the vaporizer the stream of oxygen-containing gas and/or the stream of heated oxygen-containing gas with a thermally-regulating assembly disposed in and/or in thermal communication with the conduit.

31. The method of claim 30, comprising:

discontinuing heating the stream of oxygen-containing gas with the first source of heat; and

reducing or discontinuing heating the stream of oxygen-containing gas and/or the stream of heated oxygen-containing gas with the thermally-regulated assembly.

32. The method of any one of claims 28-31, comprising:

monitoring the flow rate of the stream of heated oxygen-containing gas, the flow rate of liquid reformable fuel, the temperature of the vaporizer, the temperature of the stream of heated oxygen-containing gas and the temperature of the liquid reformable fuel; and

controlling the vaporization of the liquid reformable fuel in response to feedback from the monitoring.
