**Title:** METHOD AND APPARATUS FOR RECEIVING FULL-MOTION DIGITAL VIDEO MULTI-CASTS, INTERACTIVE DATA AND INTERACTIVE VOICE VIA A DSL CIRCUIT

**Abstract**

An IP multicast aware switched digital method and apparatus are provided in a settop unit wherein packet streams containing reference information are multicast while a select set of program information is routed to the settop units so that multicast streams can be identified and full content can be routed individually to the settop unit for decoding. Specific or preferred embodiment applications include simultaneous output and interactive communication with a television (true video on demand), computer (Internet access), videophone and telephone.
FOR THE PURPOSES OF INFORMATION ONLY

METHOD AND APPARATUS FOR RECEIVING FULL-MOTION
DIGITAL VIDEO MULTI-CASTS, INTERACTIVE DATA AND
INTERACTIVE VOICE VIA A DSL CIRCUIT

BACKGROUND OF THE INVENTION

This invention relates to the transmission of
digital multimedia communication information to end user
subscribers via bandwidth limited circuits, and more
particularly to digital subscriber line (DSL) network
transmission.

The quest to make television a truly interactive
medium has spurred technical development in the transmission
of digital video. Heretofore, technical development in this
arena focused primarily on digital data network connectivity
and specifically on connectivity to the Internet. This prior
focus on network bridging for video on demand (VoD), Internet
access, and digital compression technology is in part driven
by the perceived notion of maintaining compatibility with
conventional bus type cable television plants.

The connectionless network paradigm, which serves as
the basis of the Internet, does not commit network resources
to particular conversations as is done in circuit switched
networks. Rather, it is based upon a packet switching
paradigm in which all information travels across a
connectionless network without a specified route. While this
paradigm is ideally suited to the world of "bursty"
information delivery, applications such as digital video
distribution require the capability to specify minimum
bandwidth, controlled response times, and other Quality of
Service (QoS) parameters inherent to a circuit switched
paradigm. Known mechanisms for specifying the QoS needed are
rudimentary at best in the connectionless network model. As a
result, current connectionless, "best-effort" technological
paradigms are not suited for true switched video applications.

Switched circuit technology stands as a promising
alternative. Switched network technology serves as the basis
of the public switch telephone network. In switched networks,
conversations take place via a dedicated channel path established between the two conversing parties. This permits the quality of service of the network connection to be guaranteed. Switched circuit communication is typically performed via a twisted pair line terminating in simple jack in the subscriber's household, but the underlying technology is suited to fiber optic, coaxial cable and wireless connections up to the end user. For example, leading edge development in the switched network arena has produced the Asynchronous Transfer Mode (ATM), a high speed, multiprotocol, fiber optic network. ATM accommodates high bandwidth applications requiring certain QoS minimums, such as desktop video conferencing, imaging and voice transmission.

Internet Protocol (IP), the ubiquitous workhorse protocol of the Internet, has gained widespread popularity due to its universal compatibility with virtually any network design. The field of end-user interface devices or so-called "settop" arena has also embraced IP technology. For example, vendors of settop units such as Stellar One Corporation of Seattle, Washington and Acorn Computer Company (a.k.a. Online Media) of Cambridge, England have produced "IP-aware" settop units. Internet IP compatibility is a highly desirable feature for providing the seamless integration of television, Internet, videophone and telephone services.

One notable problem with using switch circuit technology for the distribution of digital video is that bandwidth is typically limited in digital subscriber line circuits to about 4 MPBS downstream to the end user and approximately 640 KBPS upstream. In light of the foregoing, what is needed is a technique for distributing digital video information as well as Internet access and telephone information over a limited bandwidth medium using the switched circuit paradigm.

SUMMARY OF THE INVENTION

According to the invention an IP multicast aware switched digital method and apparatus are provided in a settop unit wherein packet streams containing reference information
are multicast while a select set of program information is routed to the settop units so that multicast streams can be identified and full content can be routed individually to the settop unit for decoding.

Specific or preferred embodiment applications include simultaneous output and interactive communication with a television (true video on demand), computer (Internet access), videophone and telephone. While the details of the interface with the end user terminal are not a part of the invention, it is noteworthy that the present invention is capable of delivering multiple interactive two-way communication services, including broadcast-quality video over conventional twisted-pair telephone cabling.

Specifically, in a particular asymmetric embodiment according to the invention, information representing available programming content is fed to the end user or settop unit and the end user selects one or more of the programming content services to be delivered. Thereupon dynamic switched virtual circuits are established between the end user unit and a central office via a Digital Subscriber Line (DSL) circuit. Termination of the dynamic switched virtual circuit releases bandwidth with minimal loss of efficiency so the physical medium is available for other uses.

An advantage of a point-to-point network as herein described is that security is enhanced over a comparable cable television bus network.

A further advantage is that the system is truly interactive over the same media which delivers the services.

A still further advantage is the suitability of the system for multiple simultaneous service uses.

A still further advantage is dedicated transport bandwidth for end users.

Other advantages will be apparent upon reference to the following detailed description in connection with the accompanying drawings.
BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1A depicts a representative environment in which embodiments of the invention may be practiced;

Fig. 1B depicts a central channel server, programming content providers and subscriber settop box clients according to a particular embodiment of the invention;

Fig. 2A depicts a functional view of settop box hardware in accordance with a particular embodiment of the invention;

Fig. 2B depicts a functional view of settop box software in accordance with a particular embodiment of the invention;

Fig. 3B depicts an IGMP protocol message for use with IP;

Figs. 4A-4C depicts processing steps in a representative central office;

Fig. 4D depicts processing steps in a representative settop box; and

Fig. 4E depicts processing steps in an alternative embodiment settop box.

DESCRIPTION OF SPECIFIC EMBODIMENTS

A preferable embodiment of a digital video and interactive data and voice system according to the invention has been reduced to practice and will be made available under the trade name "CHAS™" or "CHANNEL ANNOUNCEMENT SERVICE™."

System Overview

Fig. 1A depicts a representative environment according to the invention. Central to Fig. 1 is a network with ATM network backbone 100. This ATM network is capable of fiber data rates of OC3, OC12, OC48, OC192 or as is available in the art. A plurality of content providers place information onto ATM network 100. Typical sources of content served include broadcast information 102, Internet information 104, telenetwork 106, broadcast content 108, and video 110.
In a representative central plant, a plurality of ATM switches 112 interface with network 100 to receive and distribute data from the various content sources. Information flows from ATM switches 112 via a plurality of paths 113 to a plurality of DSL modems 114. DSL modems 114 connect via DSL twisted pair lines 118 to a plurality of modems 116 in various subscribers residences or establishments. From a representative modem 116, there can be attached a telephone 120 and/or a television set via settop box 122, and/or a computer 124.

Fig. 1B depicts an overview of a digital programming content distribution system according to a particular embodiment of the present invention. One or more central channel server(s) 150 collect(s) information about available programming services distributed from a multiplicity of content providers 160. In a preferable embodiment, this information is multicast by the content providers using the session announcement protocol. Channel server 150 maintains a channel list database 170 which tracks available content channel offerings and a subscriber database 180, which contains subscriber identifications and permitted channels for each subscriber. Subscribers 190 interact with central channel server 150 to obtain programming content information, and with content providers 160 to obtain programs.

In related embodiments, the channel server 150 and content providers 160 may be co-located on the same machine, or may reside on separate machines.

In related embodiments, subscriber database 180 and channel list database 170 may be co-located on the same machine, or may reside on separate machines.

End User Hardware Overview

In a representative embodiment, the invention may be practiced using a settop box with the basic subsystems and functions depicted in Fig. 2A. In the representative system of Fig. 2A, a settop unit 10 includes bus 12, which is shown schematically as a single bus, but can also be a number of buses such as a local bus and one or more expansion buses (e.g., ADB, SCSI, ISA, EISA, MCA, NuBus, or PCI), which
interconnects subsystems such as a central processor 14, which may be an 80x86, 68xxx, RISC or other suitable microprocessor family, system memory 16, which may be RAM, ROM or a combination thereof, input/output (I/O) controller 18, an external device such as serial port 28 and parallel ports 32, detachable keyboard 30, mouse 26, fixed disk drive 32, which may be a hard disk drive or an optical drive or a CD-ROM drive or other suitable medium, and floppy disk drive 33 operative to receive a floppy disk.

Network connections are usually established through a device such as a network adapter 44 attached to one of the buses or a modem on a serial port. Network adapters may include 10 base T, 100 Base T, optical, ATM, DSL, or other network formats.

MPEG Decoder 36 and Audio subsystem 42 coupled via bus 12 provide multimedia capability.

Many other devices can be connected such as fax 38 connected via serial port 28, touch screen 40 connected directly, infrared peripheral support 34 or printer 20, connected through parallel port 22. Other devices or subsystems (not shown) may be connected in a similar manner. Also, it is not necessary for all of the devices shown in Fig. 2A to be present to practice the present invention, as discussed below. The devices and subsystems may be interconnected in different ways from that shown in Fig. 2A without impairing the operation of the system. Source code to implement processing functions in accordance with the present invention may be operably disposed in system memory 16 or stored on storage media such as fixed disk 32 or floppy disk 33.

Video interface 24 may be any standard video format, such as S-Video. Various forms of user input devices may be used with the settop unit. For example, a touch screen allows a user to point to objects on the screen to select an object and to move the selected object by pointing to a second position on the screen. Alternatively, an infrared or other coupled remotable hand held control unit may be interfaced with the settop box allowing the user to interact with the
unit, make changes, and indicate preferences. Various buttons and controls may be displayed on the screen for activation by using the mouse or touch screen.

As depicted by block diagram 202 in Fig. 2B, operatively disposed in memory 16, or resident on fixed disk 32, operating system software 210, may be PSOS, DOS, UNIX, WINDOWS95, WINDOWS CE, or other operating systems known in the art. Executing concurrently and cooperatively with operating system software 210, IP Multicast capable TCP/IP software 212 manages the flow of information into and out of the settop unit over the network interface 44. A JAVA enabled Internet browser 214, such as Netscape Navigator™, Microsoft Explorer™ or their equivalent in the art provide a web-browser user interface to networked resources through TCP/IP software 212. Client control code 216 implements functions specific to the settop box operation, such as the processes depicted herein in Fig. 4D and described hereinafter. Output to the users set is provided by user interface 218 in conjunction with Video Interface Code 220. Other clients 222 such as Email, facsimile, video conferencing applications or voice mail are also supported.

In a related embodiment, the functions of the settop unit are integrated into a television, forming an Internet capable, interactive "Smart Television."

In a related embodiment, the functions of the settop unit are integrated into a personal computer, forming an Internet capable, interactive "Workstation Television."

Software Overview: Protocols

The Internet protocol (IP), which forms the basis of all other protocols in the Transmission Control Protocol/Internet Protocol (TCP/IP) protocol suite, has three operating modes of transmitting and receiving information: unicast, broadcast, and multicast. In the most familiar of these, unicast, information flows from a single source host to a single destination host. The destination address within the IP packet header specifies a specific host address in a unicast. Two hosts communicating in this manner do not share
information with any of the remaining hosts on the line. A second type of service called broadcast is used when a host desires to send a frame to every other host on the wire. Broadcasting is a single source to all destinations on the wire paradigm. Finally, multicasting fits between unicasting and broadcasting. In multicasting, information packets are delivered only to the set of hosts that belong to a multicast group.

Fig. 3A depicts the format of a class D IP address used in multicasting applications. An IP multicast application will specify an IP host group address, rather than an individual IP address, in the destination field. As depicted in Fig. 3A, the IP host group address has its first four highest order bits permanently fixed to 1110. This yields a dotted decimal notation range of 224.0.0.0 to 239.255.255.255. The remaining 28 bits in the address comprise the multicast group identifier.

An IP multicast may be used to deliver digitized information such as video conferencing or television to an end user host. Since multicasting directs the same packets of information to multiple destinations simultaneously, it is more efficient than a unicasting model which sends separate copies to each individual destination. Other benefits of multicasting include: (1) The sender need only send one copy of the information packet. (2) The information is delivered in a more timely synchronized fashion because all destinations receive the same source packet. (3) Multicasting may be used to send information to destinations whose individual addresses are unknown to the sender, thus reducing the overall number of packets in the network.

A fundamental aspect of implementing a multicast system is the concept of end user hosts joining multicast groups. This is accomplished by means of an Internet Group Management Protocol (IGMP) transaction. Fig. 3B depicts the format of an IGMP message. IGMP messages are always eight bytes in length. They begin with a four bit IGMP version which is currently "1" in contemporary releases of TCP/IP. Next follows a four bit IGMP type field. Type fields may be a
"1" indicating a query sent by a multicast router, or a "2" indicating a response sent by a host. The next eight bits are unused. Bits 16 through 31 form a 16 bit checksum. Bits 32 through 64 comprise a 32 bit group address.

Multicast traffic is managed throughout a network using exchanges of queries and reports between hosts and routers on the network. An Internet host sends an IGMP report when it first joins a multicast group. A router receiving such a report will update its internal table of interfaces for the interface of the multicast group which the host has requested to join. Subsequently, whenever the router receives a multicast datagram, it forwards the datagram only to the interfaces having hosts belonging to corresponding multicast groups. Additionally, routers will send out IGMP queries at regular intervals to see if any hosts continue to belong to any groups. The router will send one query out each interface. In this fashion, IGMP transactions are used to track membership in multicast groups by multicast routers.

Multicast conference sessions are announced using Session Announcement Protocol (SAP). An SAP server that announces a conference session periodically multicasts an announcement packet to a well known multicast address and port. The announcement is multicast with the same scope, as defined by group address range or Time To Live (TTL) field, as the session it is announcing. (Multicasts with the TTL field set to 0 are restricted to their sending hosts' IP subnet; while those with larger values for TTL will be forwarded to other subnets by routers.) This ensures that the recipients of the announcement can also be potential recipients of the session the announcement describes, bandwidth and other such constraints permitting. This is also important for the scalability of the protocol, as it keeps local session announcements local. The time period between one announcement and its repetition is dependent on two factors - the scope (TTL) of the session, and the number of other sessions currently being announced by other session directory clients.

A session announcement is simply multicast to the appropriate well known multicast address and port. The
announcement contains a session description and, optionally, an authentication header. The session description may be encrypted. Multicast addresses 224.2.127.254, for SAP version 1 announcements; 224.2.127.255, for SAP version 0 announcements; and 224.2.128.0 to 224.2.255.255, for SAP Dynamic Assignments, are reserved for the session announcement protocol. Multicast address assignments are more fully described in, Deering, S., "Host Extensions for IP Multicasting", STD 5, RFC 1112, Stanford University, August 1989, which is incorporated herein by reference in its entirety for all purposes.

Content transmission based upon the unicast model in a particular embodiment of the present invention employs the Hyper Text Transfer Protocol (HTTP). The Hypertext Transfer Protocol is a simple protocol built on top of Transmission Control Protocol (TCP). It is the mechanism which underlies the function of the World Wide Web. The HTTP provides a method for users to obtain data objects from various hosts acting as servers on the Internet. User requests for data objects are made by means of an HTTP request, such as a GET request. A GET request as depicted below is comprised of 1) an HTTP protocol version, such as "http:/1.0"; followed by 2) the full path of the data object; followed by 3) the name of the data object. In the GET request shown below, a request is being made for the data object with a path name of "/pub/" and a name of "MyData.html":

HTTP-Version GET /pub/MyData.html

(1)

Processing of a GET request entails the establishing of an TCP/IP connection with the server named in the GET request and receipt from the server of the data object specified. Subsequently, the TCP/IP connection with the server is terminated.

Distributing Digital Programming

Figs. 4A, 4B and 4C depict processing steps which occur in a typical central office according to a particular
embodiment of the invention. In flow chart 401, processing step 400, each content provider sends to the centralized channel server session announcement information, comprising its own unique identifier, further comprising the channel source address, which can be an IP address for example, or perhaps an ATM Virtual Path (VP), and transmission circuit, which can be a User Datagram Protocol (UDP) port for example, or perhaps an ATM Virtual Channel (VC), and, in a preferable embodiment, a brief content descriptor, which may be a segment of the actual program. The session announcement information is sufficient to enable a settop box subscriber to access a particular content provider to receive content information packets. The channel server, in conjunction with the channel database, tracks the identifier source and address information of the content providers.

Flow chart 403 of Fig. 4B depicts a set of verification steps that the channel server will undertake responsive to a subscriber request for a particular program. In accordance with a particular embodiment, subscriber requests may be made of the channel server by unicast from a settop box in the subscriber's residence. Beginning with step 410, the channel server seeks to determine the identification of the subscriber making such request and the particular channels permitted to this subscriber. In step 412, the channel server will fetch the address from the subscriber's incoming request. In alternative embodiments, this address information may be the Media Access Control (MAC) address associated with the user's network adapter, or in cases where there is no MAC address, such as an ATM network, the IP address associated with the end user's unit may be obtained from the packet. Next, in step 414, the channel server searches a database of customers, using the subscriber's address information as the search key, to determine the subscriber's unique identification in the network. In step 416 the subscriber's identification is used to search a subscribed channel list database. In step 417, the subscribed channel list is retrieved by the channel server. The subscribed channel list contains a listing of programming
content which is both 1) being offered by a content provider; and 2) permitted to be viewed by the requesting subscriber.

In step 418, the server sends the subscribed channel list to the settop box of the subscriber via unicast. The result is that the subscriber at the settop box is only able to view programming content for which the subscriber has permission to access. Subsequently, subscribers will make a choice of programming by their settop box. This choice is then communicated from the settop box back through the network in the form of a request to receive a particular channel. In a preferable embodiment, this request may be made by an IGMP request to join a multicast group associated with the particular channel. In an alternative embodiment, an http text transfer protocol (HTTP) request to get a particular uniform resource locator (URL) of a particular channel may also be used.

In related embodiments, step 413 (not shown) is interposed between steps 412 and 414. In step 413, the Address Resolution Protocol (ARP) is used to obtain a MAC address from an IP address obtained from the packet. The resulting MAC address can then be used to search the subscriber database in step 414. In another related embodiment, in step 413, the Reverse Address Resolution Protocol (RARP) is used to translate a MAC address to an IP address. The resulting IP address can then be used to search the subscriber database in step 414.

Fig. 4C, flow chart 405 depicts processing of incoming requests by subscribers to receive a particular channel. In step 420, an IP level conversation is established between the channel content provider and a particular subscriber. In step 422, channel programming content flows via a switched virtual circuit from the content provider via the central office to the subscriber's settop box. In a preferable embodiment, digital video and channel content are distributed to the subscriber's settop box by way of multicasting. In an alternative embodiment, a unicast model may be used in which a dedicated TCP/IP connection exists between a settop box and the content provider. Some time
later, responsive to a subscriber request in step 430, the conversation between the subscriber's settop box and the content provider is terminated.

Flowchart 407 of Fig. 4D depicts the processing steps of a representative settop box in accordance with a particular embodiment of the invention. The settop box is preconfigured to transmit by unicast to the channel server, a request for programming announcement information, as depicted in step 450 of flowchart 407. Note that this request will carry with it the address information of the user's settop unit, which may be, in alternative embodiments, the Media Access Control (MAC) address associated with the user's network adapter, or in cases where there is no MAC address, such as an ATM network, the IP address associated with the end user's unit obtained from the packet. The channel server will respond with a subscriber channel list, as depicted in flow chart 403 of Fig. 4B and described hereinabove. The settop box receives information about programming content for which the settop box subscriber is permitted to access to in step 452. The information received in step 452 by the settop box is organized in step 454 as a menu and presented to the user by graphical user interface.

In a related embodiment, MAC addresses may be used as subscriber identifiers on ATM networks by encapsulating the MAC addresses in ATM cells, such as AAL5 cells, to move them across the network. Encapsulating information in ATM cells is well known to those of ordinary skill in the art, and is more fully detailed in references such as, George Sackett & Christopher Metz, "ATM and Multiprotocol Networking", 1996.

Responsive to the user's selection of desired programming content, the settop box transmits a request back through the network for a particular channel in step 456. In a preferable embodiment, this join request may be implemented by an IGMP protocol request to join a multicast group. In an alternative embodiment, an HTTP protocol GET request may be made for the specific uniform resource indicator of the particular channel. Subsequently, in step 460, the settop box receives program content from the content provider via a
switched virtual circuit established through the central office. In a preferable embodiment, the transport of video information to the end user is accomplished via multicasting. In an alternative embodiment, video information may be received from the central office via point-to-point TCP connection.

After some time, the user may indicate to the settop box, the desire to change or terminate receiving programming content. In step 470, the settop box terminates the switched virtual circuit upon such notice by the user. In a preferable embodiment, this is accomplished by means of an IGMP request to leave the multicast group of the host providing the content. In an alternate embodiment, this can be a TCP Abort or TCP Close request to sever a unicast connection between the content provider and the settop box.

In the related embodiment depicted by flow chart 409 in fig. 4E, decisional step 455 shows processing within the settop box to check if the channel requested by the user, either multicast group in the preferable embodiment, or uniform resource indicator in an alternate embodiment, is a member of the most recent channel list sent from the channel server. If it is not a member, then the system has detected an intrusion attempt by the subscriber and declines to process the subscriber’s selection request. The remainder of the processing steps in this embodiment closely mirror the steps in the embodiment depicted by flow chart 407 in fig. 4D.

In a related embodiment, processing will truncate IP header information from video content carried entirely over switched networks to save bandwidth. Headers are prepended to information by the various entities comprising the TCP/IP protocol stack to contain information useful to non-switched networks in routing the packet. For example, IP headers contain a source and destination address. UDP headers contain network addresses and ports. These headers are of a standard size and layout, which are well known to those of ordinary skill in the art. Packets flowing on a switched virtual circuit travel along a point to point link, and therefore have no need for the routing information contained within the IP
header. ATM networks are one example of networks using virtual circuits. Thus, whenever information packets cross a border onto a virtual circuit network, the border entity, which may be for example a router or an ATM edge machine, perhaps, can strip off these prepended headers.

The invention has now been explained with reference to specific embodiments. Other embodiments will be apparent to those of ordinary skill in the art. It is therefore not intended that the invention be limited except as indicated by the appended claims.
WHAT IS CLAIMED IS:

1. A method for receiving digital information comprising:
   distributing multicast header information representing multicast services available to end user units;
   thereupon
   selecting at each end user unit only one or more of the multicast services to be delivered; and thereupon
   establishing a dynamic switched virtual circuit between the end user unit and a central office via a dedicated
   DSL circuit for supplying said selected one or more of the multicast services.

2. The method according to claim 1 further including the step of suppressing said multicast header information upon establishing said switched virtual circuit.

3. The method according to claim 1 further comprising the step of verifying that the end user unit is authorized for the multicast service to be delivered in the selecting step.

4. The method according to claim 1 further comprising the steps of:
   prompting at said end user unit for a plurality of filtering parameters; and
   filtering said digital information according to said plurality of filtering parameters.

5. The method according to claim 1 further comprising the steps of:
   prompting at said end user unit for one or more values for a plurality of customizable settings; and
   applying said values to said plurality of customizable settings.
6. A method for receiving digital information from a plurality of content providers comprising:
   distributing information representing programming services available to a plurality of end user units; thereupon selecting at each end user unit only one or more of the programming services to be delivered; and thereupon establishing a dynamic switched virtual circuit between the end user unit and a central office via a dedicated DSL circuit for supplying said selected one or more of the programming services.

7. The method of claim 6 wherein said distributing step further comprises IP multicasting.

8. The method of claim 6 wherein said information comprises program identification information; source address information; and a program description.

9. The method of claim 8 wherein said information further comprises a segment of program content.

10. The method of claim 6 wherein said plurality of content providers provide programming content by multicast, and are associated with a multicast group.

11. The method of claim 10 wherein said supplying said selected one or more of the programming services further comprises:
   sending an IGMP join request from said end user unit to said central office in order to join said multicast group of a particular content provider of said plurality of content providers; and
   receiving from said particular content provider multicast programming content.

12. The method of claim 6 wherein said plurality of content providers provide programming content by unicast, and are associated with a unique uniform resource locator (URL).
13. The method of claim 12 wherein said supplying said selected one or more of the programming services further comprises:
   sending an HTTP GET request from said end user unit to said central office in order to obtain programming content from a particular content provider of said plurality of content providers; and
   receiving from said particular content provider unicast programming content.

14. The method according to claim 6 further comprising the step of verifying that the end user unit is authorized for the program service to be delivered in the selecting step.

15. The method according to claim 6 further comprising the step of verifying that the only one or more of the programming services to be delivered in the selecting step is contained in said programming services available in the distributing information step; and
   if not so contained, generating a security exception.

16. The method according to claim 6 further comprising the steps of:
   prompting at said end user unit for a plurality of filtering parameters; and
   filtering said digital information according to said plurality of filtering parameters.

17. The method according to claim 6 further comprising the steps of:
   prompting at said end user unit for one or more values for a plurality of customizable settings; and
   applying said values to said plurality of customizable settings.
18. A system for distributing digital information comprising:
   a plurality of content providers, distributing information representing available programming services;
   a central channel server for receiving said information representing available programming services;
   a plurality of end user subscribers, interactively receiving from said central channel server said information representing programming services available, selecting only one or more of the programming services to be delivered, and thereupon become connected via dynamic switched virtual circuits established between said end user units and a central office via a dedicated DSL circuit for supplying said selected one or more of the programming services.

19. A computer program product comprising:
   code for transmitting requests for program announcement information to a server;
   code for receiving programming announcement information;
   code for transmitting a selection of programming from the user to the server;
   code for establishing a session for receiving programming content from a content provider;
   and a computer readable storage medium for storing the codes.

20. The computer program product of claim 19 wherein said code for establishing a session further comprises code for joining an IP multicast group.

21. The computer program product of claim 19 wherein said code for establishing a session further comprises code for retrieving program content from a source by TCP connection.

22. The computer program product of claim 19 further comprising code for verifying that the selection of
programming from the user was contained in the program announcement information.

23. The computer program product of claim 19 further comprising code for allowing user to customize setting.

24. The computer program product of claim 19 further comprising code for allowing user to filter unwanted content.

Process Requests from subscriber clients joining channels

Fetch MAC address from Subscriber's request to join channel

Search subscriber database by MAC address to obtain user's identifier

Search channel list database using subscriber's identifier

Retrieve subscribed channel list from channel list database

Server Sends subscribed Channel list to Subscriber

Content Providers Distribute via multicasting Session Announcements (SAP)

Central Channel Server incorporates SAP information into Channel list database

Establish switched virtual circuit between subscriber and central office

Distribute via switched virtual circuit information services

Terminate switched virtual circuit in response to subscriber request
Transmit to Channel Server Request for Programming Announcements

Receive information about available Programming Services

Provide a menu of Programming available to the user

Transmit Request to join the Selected Channel

Receive Programming

Terminate the Reception of Programming Services

Fig. 4D
Transmit to Channel Server Request for Programming Announcements

Receive information about available Programming Services

Provide a menu of Programming available to the user

Channel selected one of the available services?

Yes

Transmit Request to join the Selected Channel

Receive Programming

Terminate the Reception of Programming Services

No

SUBSTITUTE SHEET (RULE 26)
