(57) **Abrégé/Abstract:**

Provided are compositions and methods for preparing and identifying antibodies having CDR3s that vary in sequence and in length from very short to very long which in certain embodiments may bind to a carbohydrate moiety or the active site of an enzyme. Libraries coding for antibodies with the CDR3s are also provided. The libraries can be provided by modifying a pre-existing nucleic acid library.

81802136

ABSTRACT

Provided are compositions and methods for preparing and identifying antibodies having CDR3s that vary in sequence and in length from very short to very long which in certain embodiments may bind to a carbohydrate moiety or the active site of an enzyme. Libraries coding for antibodies
5 with the CDR3s are also provided. The libraries can be provided by modifying a pre-existing nucleic acid library.

LIBRARIES OF GENETIC PACKAGES COMPRISING NOVEL HC CDR1, CDR2, AND CDR3 AND NOVEL LC CDR1, CDR2, AND CDR3 DESIGNS

CROSS REFERENCE TO RELATED APPLICATIONS

5 This application is a division of application 2722409 filed April 24, 2009.

BACKGROUND

[0001] It is now common practice in the art to prepare libraries of genetic packages that individually display, display and express, or comprise a member of a diverse family of peptides, polypeptides or proteins and collectively display, display and express, or comprise at least a
10 portion of the amino acid diversity of the family. In many common libraries, the peptides, polypeptides or proteins are related to antibodies (e.g., single chain Fv (scFv), Fv, Fab, whole antibodies or minibodies (i.e., dimers that consist of V_H linked to V_L)). Often, they comprise one or more of the CDRs and framework regions of the heavy and light chains of human antibodies.

[0002] Peptide, polypeptide or protein libraries have been produced in several ways. See, e.g.,
15 Knappik et al., *J. Mol. Biol.*, 296, pp. 57-86 (2000). One method is to capture the diversity of native donors, either naïve or immunized. Another way is to generate libraries having synthetic diversity. A third method is a combination of the first two. Typically, the diversity produced by these methods is limited to sequence diversity, i.e., each member of the library has the same length but differs from the other members of the family by having different amino acids or variegation
20 at a given position in the peptide, polypeptide or protein chain. Naturally diverse peptides, polypeptides or proteins, however, are not limited to diversity only in their amino acid sequences. For example, human antibodies are not limited to sequence diversity in their amino acids, they are also diverse in the lengths of their amino acid chains.

25 **SUMMARY**

[0003] For antibodies, heavy chain diversity in length occurs, for example, during variable region rearrangements. See e.g., Corbett et al., *J. Mol. Biol.*, 270, pp. 587-97 (1997). The joining of V genes to J genes, for example, results in the inclusion of a recognizable D segment in CDR3

in about half of the heavy chain antibody sequences, thus creating regions encoding varying lengths of amino acids. D segments are more common in antibodies having long HC CDR3s. The following also may occur during joining of antibody gene segments: (i) the end of the V gene may have zero to several bases deleted or changed; (ii) the end of the D segment may have zero to many bases removed or changed; (iii) a number of approximately random bases may be inserted between V and D or between D and J; and (iv) the 5' end of J may be edited to remove or to change several bases. These rearrangements result in antibodies that are diverse both in amino acid sequence and in length. HC CDR3s of different lengths may fold into different shapes, giving the antibodies novel shapes with which to bind antigens. The conformations depend on both the length and the sequence of the CDR3. It should be remembered that a HC CDR3 of length 8, for example, and of any sequence cannot adequately mimic the behavior of a CDR3 of length 22, for example.

[0004] Libraries that contain only amino acid sequence diversity are, thus, disadvantaged in that they do not reflect the natural diversity of the peptide, polypeptide or protein that the library is intended to mimic. Further, diversity in length may be important to the ultimate functioning of the protein, peptide or polypeptide. For example, with regard to a library comprising antibody regions, many of the peptides, polypeptides, proteins displayed, displayed and expressed, or comprised by the genetic packages of the library may not fold properly or their binding to an antigen may be disadvantaged, if diversity both in sequence and length are not represented in the library.

[0005] An additional disadvantage of such libraries of genetic packages that display, display and express, or comprise peptides, polypeptides and proteins is that they are not focused on those members that are based on natural occurring diversity and thus on members that are most likely to be functional and least likely to be immunogenic. Rather, the libraries, typically, attempt to include as much diversity or variegation as possible at every CDR position. This makes library construction time-consuming and less efficient than necessary. The large number of members that are produced by trying to capture complete diversity also makes screening more cumbersome than it needs to be. This is particularly true given that many members of the library will not be functional or will be non-specifically sticky.

[0006] In addition to the labor of constructing synthetic libraries is the question of immunogenicity. For example, there are libraries in which all CDR residues are either Tyr (Y)

or Ser (S). Although antibodies (Abs) selected from these libraries show high affinity and specificity, their very unusual composition may make them immunogenic. The present invention is directed toward making Abs that could well have come from the human immune system and so are less likely to be immunogenic. The libraries of the present invention retain as many
5 residues from V-D-J or V-J fusions as possible. To reduce the risk of immunogenicity, it may be prudent to change each non-germline amino acid in both framework and CDRs back to germline to determine whether the change from germline is needed to retain binding affinity. Thus, a library that is biased at each varied position toward germline will reduce the likelihood of isolating Abs that have unneeded non-germline amino acids.

10 [0007] Abs are large proteins and are subject to various forms of degradation. One form of degradation is the deamidation of Asn and Gln residues (especially in Asn-Gly or Gln-Gly) and the isomerization of Asp residues. Another form of degradation is the oxidation of methionines, tryptophan, and cysteine. Another form of degradation is the cleavage of Asp-Pro dipeptides. Another form of degradation is the formation of pyroglutamate from N-terminal Glu or Gln. It is
15 advantageous to provide a library in which the occurrence of problematic sequences is minimized.

[0008] Provided are libraries of vectors or packages that encode members of a diverse family of human antibodies comprising heavy chain (HC) CDR3s that are between about 3 amino acids in length to about 35 amino acids in length. The HC CDR3s may also, in certain embodiments,
20 may be rich in Tyr (Y) and Ser (S) and/or comprise diversified D regions and/or comprise extended JH regions. For example, the HC CDR3s may contain greater than about 40% (e.g., between about 43% and about 80%; e.g., greater than about 40% but less than about 100%) Y and/or S residues, e.g., as provided in the examples herein. Also provided are focused libraries comprising such HC CDR3s. Also provided are designs for HC CDR1, HC CDR2, and a library
25 of VKIII A27 with diversity in the CDRs. A library of vectors or packages that encode members of a diverse family of human antibodies comprising HC CDR3s described herein can further have diversity at one or more (e.g., at one, two or three) of HC CDR1, HC CDR2, LC CDR1, LC CDR2, and LC CDR3. For example, the library can have diversity at one or more (e.g., at one, two or three) of HC CDR1, HC CDR2, LC CDR1, LC CDR2, and LC CDR3 as described herein.

[0009] A diversified D region is a D region into which one or more amino acid changes have been introduced (e.g., as compared to the sequence of a naturally occurring D region; for example, a stop codon can be changed to a Tyr residue).

[0010] An extended JH region is a JH region that has one or more amino acid residues present at the amino terminus of the framework sequence of the JH region (e.g., amino terminal to FR4 sequences, e.g., which commence with WGQ ...). For example, JH1 is an extended JH region. As other examples, JH2, JH3, JH4, JH5, and JH6 are extended JH regions.

[0011] Provided also are methods of making and screening the above libraries and the HC CDR3s and antibodies obtained in such screening. Compositions and kits for the practice of these methods are also described herein.

[0012] In some aspects, the disclosure features a focused library of vectors or genetic packages that display, display and express, or comprise a member of a diverse family of human antibody related peptides, polypeptides and proteins (e.g., a diverse family of antibodies) and collectively display, display and express, or comprise at least a portion of the diversity of the family, wherein the vectors or genetic packages comprise variegated DNA sequences that encode a heavy chain (HC) CDR3 selected from the group consisting of:

(a) a HC CDR3 that is about 3 or about 4 or about 5 amino acids in length;

(b) a HC CDR3 that is about 23, about 24, about 25, about 26, about 27, about 28, about 29, about 30, about 31, about 32, about 33, about 34 or about 35 amino acids in length (e.g., about 23 to about 35 amino acids in length); and

(c) a HC CDR3 that is from about 6 to about 20 amino acids in length (e.g., about 6, about 7, about 8, about 9, about 10, about 11, about 12, about 13, about 14, about 15, about 16, about 17, about 18, about 19, or about 20 amino acids in length);

wherein the HC CDR3 comprises amino acids from a D region (e.g., a diversified D region) (or fragment thereof (e.g., 3 or more amino acids of the D region, e.g., diversified D region)) or a JH region (e.g., an extended JH region).

[0013] In some embodiments, the HC CDR3 is enriched in Tyr (Y) and Ser (S) (e.g., greater than 40% of the residues of the HC CDR3 are Y and/or S).

[0014] In some embodiments, the library (e.g., the vectors or genetic packages thereof)

comprises a D region or a fragment of a D region (e.g., wherein the D region is adjacent to a JH region).

[0015] In some embodiments, the library comprises a JH region, e.g., an extended JH region.

[0016] In some embodiments, the HC CDR3 comprises amino acids from a D region or a fragment of a D region (e.g., wherein the D region is adjacent to a JH region).

[0017] In some embodiments, the D region is selected from the group consisting of D2-2 (RF 2),
5 D2-8(RF 2), D2-15(RF 2), D2-21(RF 2), D3-16(RF 2), D3-22 (RF 2), D3-3 (RF-2), D3-9 (RF 2),
D3-10 (RF 2), D1-26 (RF 3), D4-11 (RF 2), D4-4 (RF 2), D5-5 (RF 3), D5-12 (RF 3), D5-18
(RF 3), D6-6 (RF1), D6-13 (RF 1), and D6-19 (RF 1).

[0018] In some embodiments, the HC CDR3 comprises amino acids from a JH region. The JH
region may be an extended JH region. In some embodiments, the extended JH region is selected
10 from the group consisting of JH1, JH2, JH3, JH4, JH5, and JH6. In some embodiments, the JH
region may be enriched in Y and/or S residues, for example, it may contain greater than about
40% (e.g., between about 43% and about 80%; e.g., greater than about 40% but less than about
100%) Y and/or S residues.

[0019] In some embodiments, the D region comprises one or more cysteine (Cys) residues and in
15 some embodiments, the one or more Cys residues are held constant (e.g., are not varied).

[0020] In some embodiments, the HC CDR3 (e.g., the DNA encoding the HC CDR3) comprises
one or more filling codons between FR3 and the D region and each filling codon is individually
NNK, TMY, TMT, or TMC (TMY, TMT, or TMC encode S or Y).

[0021] In some embodiments, the HC CDR3 (e.g., the DNA encoding the HC CDR3) comprises
20 one or more filling codons between the D region and JH and each filling codon is individually
NNK, TMY, TMT, or TMC.

[0022] In some embodiments, the library (e.g., the vectors or genetic packages of the library)
further comprises a HC CDR1, HC CDR2, and/or a light chain and also comprises diversity in
the HC CDR1, HC CDR2, or light chain comprises diversity in HC CDR1 and/or HC CDR2,
25 and/or a light chain (e.g., kappa or lambda light chain) (respectively). For example, HC CDR3
diversity can be constructed in the background of diversity in HC CDR1, HC CDR2, and/or light
chains. For example, the light-chain diversity may be encoded in the same DNA molecule as the
HC diversity or the LC and HC diversities may be encoded in separate DNA molecules.

[0023] In some aspects, the disclosure features a library comprising a HC CDR3 that is 3, 4, or 5
30 amino acids in length, wherein the CDR3 comprises amino acids from a JH region (e.g.,

extended JH region) or from a D region (e.g., a diversified D region) (or fragment thereof (e.g., 3 or more amino acids of the D region, e.g., diversified D region)) joined to the FR4 portion of a JH region.

5 [0024] In some embodiments, the HC CDR3 is from a D region joined to the FR4 portion of a JH region and comprises a trimer, a tetramer, or a pentamer, wherein the trimer, tetramer, or pentamer does not comprise a cysteine residue.

[0025] In some embodiments, the HC CDR3 is from a D region joined to the FR4 portion of a JH region and comprises a trimer, a tetramer, or a pentamer, wherein the trimer, tetramer, or pentamer does not comprise a stop codon.

10 [0026] In some embodiments, the D region (e.g., the DNA encoding the D region) comprises a TAG codon and the TAG codon is replaced by a codon selected from the group consisting of TCG, TTG, TGG, CAG, AAG, TAT, and GAG.

[0027] In some embodiments, the D region (e.g., the DNA encoding the D region) comprises a TAA codon and the TAA codon is replaced by a codon selected from the group consisting of
15 TCA, TTA, CAA, AAA, TAT, and GAA.

[0028] In some embodiments, the D region (e.g., the DNA encoding the D region) comprises a TGA codon and the TGA codon is replaced by a codon selected from the group consisting of TGG, TCA, TTA, AGA, and GGA.

[0029] In some embodiments, the library further comprises diversity in HC CDR1 and/or HC
20 CDR2, and/or a light chain (e.g., kappa or lambda light chain). For example, HC CDR3 diversity can be constructed in the background of diversity in HC CDR1, HC CDR2, and/or light chains. For example, the light-chain diversity may be encoded in the same DNA molecule as the HC diversity or the LC and HC diversities may be encoded in separate DNA molecules.

25 [0030] In some aspects, the disclosure provides a method of diversifying a library, the method comprising mutagenizing a library described herein.

[0031] In some embodiments, the mutagenizing comprises error-prone PCR.

[0032] In some embodiments, the mutagenizing comprises wobbling.

[0033] In some embodiments, the mutagenizing comprises dobbing.

[0034] In some embodiments, the mutagenizing introduces on average about 1 to about 10 mutations (e.g., about 1, about 2, about 3, about 4, about 5, about 6, about 7, about 8, about 9, about 10 mutations; e.g., base changes) per HC CDR3.

5 [0035] "Wobbling" is a method of making variegated DNA so that an original sequence is favored. If the original sequence had, for example, an Ala that could be encoded with GCT the mixture (0.7 G, 0.1 A, 0.1 T, 0.1 C) can be used for the first position, (0.7 C, 0.1 A, 0.1 T, 0.1 G) at the second position, and (0.7 T, 0.1 A, 0.1 G, 0.1 C) at the third. Other ratios of "doping" can be used. This allows Ala to appear about 50% of the time while V, D, G, T, P, and S occur about
10 7% of the time. Other AA types occur at lower frequency.

[0036] In some aspects, the present disclosure is drawn, e.g., to keeping a (purified) HC CDR1-2 repertoire, and building synthetic HC CDR3 and LC diversity.

[0037] In some embodiments, the disclosure provides a cassette for displaying a wobbled heavy chain (HC) CDR3, for example, wherein the cassette comprises the cassette shown in Table 400.

15 [0038] In some aspects, the present disclosure features a library in which Tyr levels are controlled in the HC CDR3. In some embodiments, the HC CDR3 regions contain about 15% or greater (e.g., about 16%, about 18%, about 20%, or greater) Tyr residues. In some embodiments, high levels (e.g., more than about 20%) of Tyr are inserted into the HC CDR3 of library
20 members, e.g., at D regions and J stumps (or synthetic sequences corresponding thereto) that contain Tyr. In some embodiments, at leadin or DJ filler positions (or synthetic sequences corresponding thereto), Tyr is allowed, but at no more than 20%. In some embodiments, the HC CDR3 regions contain less than about 15% (e.g., about 14%, about 12%, about 10%, about 8%, about 6% or less) Tyr residues. In some embodiments, the HC leadin or DJ filler positions (or
25 synthetic sequences corresponding thereto) contain less than about 15% (e.g., about 14%, about 12%, about 10%, about 8%, about 6% or less) Tyr residues.

[0039] In some aspects, the disclosure features a library of genetic packages that encode a human antibody heavy chain in which a parent amino-acid sequence comprises a VH sequence
30 followed by zero to ten amino acids selected from the group consisting of (Y, S, D, L, R), followed by a human D-region or fragment of a D-region, followed by zero to ten amino acids

selected from the group consisting of (Y,S,R,D,L), followed by a JH segment that comprises at least W103 onward wherein the variable DNA encoding this sequence is synthesized in a way that the parental amino-acid sequence is the most likely one (e.g., by wobbling).

5 [0040] In some aspects, the disclosure features a library of light chains having germline framework regions and wherein the CDRs are varied such that residues remote from the combining site or having buried side groups are held constant. In some embodiments, a method of variable DNA synthesis is used so that germline sequence is the most likely one (e.g., by wobbling).

10

[0041] In some aspects, the disclosure features a library of diverse members encoding antigen binding variable regions as disclosed herein.

[0042] In some aspects, the disclosure features a library of diverse members encoding HC CDR3 regions as disclosed herein. In some embodiments, the library is a library of Table 1097.

15 [0043] In some aspects, the disclosure features a library of diverse members, each member encoding comprising a HC CDR 3, wherein

at least 1, 2, 3, 4, 5, 6, 7, or 8 positions in the HDCR3, respectively, is occupied by G, S, R, D, L, and Y in the library in the following proportions [1.0G, .57S, .46R, .42D, .36L, .35Y] and optionally,

20

the last 4 positions of HC CDR3 are represented as follows:

the parental amino acid is present at 3, 4, 5, 6, 7, 8, 10 times as likely as other amino-acid types, wherein the other amino-acid types comprise Y, S, D, R, G.

[0044] In some aspects, the disclosure features a library of diverse members, each member encoding comprising a HC CDR 3, wherein

25

at least one and preferably all of the first 1, 2, 3, 4, 5, 6, 7, or 8 positions in the HC CDR3, is occupied by G, S, R, D, L, and Y, in the library in the following proportions [1.0G, .57S, .46R, .42D, .36L, .35Y] and optionally

the last 4 positions of HCDR3 are represented as follows:

30 the parental amino acid is present at 3, 4, 5, 6, 7, 8, 10 times as likely as other amino-acid types, wherein the other amino-acid types comprise Y, S, D, R, G.

[0045] In some aspects, the disclosure features a library of diverse members, each member encoding a HC CDR 3, wherein

the length of HC CDR3 is 10, 11, or 12 positions;

each of the first 6, 7, or 8 positions in the HC CDR3, respectively, is occupied by G, S,
5 R, D, L, and Y in the library in the following proportions [1.0G, .57S, .46R, .42D, .36L, .35Y];

the last 4 positions of HCDR3 are represented as follows:

the parental amino acid is present at 3, 4, 5, 6, 7, 8, 10 times as likely as other amino-acid types, wherein the other amino-acid types comprise Y, S, D, R, G.

[0046] In some embodiments, each of the last 4 HC CDR3 positions is represented in the library
10 as 7/12 parental, plus 1/12 each of Y, S, D, R, and G.

[0047] In some embodiments, each of the last 4 HC CDR3 positions is represented in the library as A6= 7/12 A, plus 1/12 each of Y, S, D, R, and G; F7 = 7/12 F plus 1/12 each of Y, S, D, R, and G; D8 = 7/11 D plus 1/11 of Y, S, R, and G; I9 = 7/12 I plus 1/12 Y, S, R, D, G.

[0048] In some embodiments, the members further encode HC CDR1, HC CDR2.

15 [0049] In some embodiments, the members further encode Fframework (FR) regions 1-4.

[0050] In some embodiments, the members encode HC CDR1, HC CDR2 and FR regions 1-4.

[0051] In some embodiments, the members comprise a 3-23 HC framework.

[0052] In some embodiments, the library further comprises a LC variable region.

20 [0053] In some embodiments, the library comprises members encoding diverse LC variable regions.

[0054] In some embodiments, the members comprising a LC variable region comprise an A27 LC framework.

[0055] In some embodiments, the library is a display library, e.g., a phage display library.

25 [0056] In some embodiments, the library has at least 10^4 , 10^5 , 10^6 , 10^7 , 10^8 , 10^9 , 10^{10} , 10^{11} diverse members.

[0057] In some aspects, the disclosure features a method of selecting a library member, comprising: contacting a library described herein with a target, allowing a member to bind to said target, and recovering the member which binds the target.

30

[0057a] In some aspects, the disclosure features a library of vectors or genetic packages, wherein the vectors or genetic packages comprise a first set of variegated DNA sequences that encode a first plurality of antibody heavy chain (HC) variable regions each comprising a heavy chain complementary determining region 1 (HC CDR1), a heavy chain complementary determining region 2 (HC CDR2) and a heavy chain complementary determining region 3 (HC CDR3), wherein the HC CDR3 regions encoded by the first set of variegated DNA sequences are three amino acids in length and: (i) the first residue of HC CDR3 varies among F, S, Y, D, and R in a 3:1:1:1:1 ratio; the second residue of HC CDR3 varies among Q, E, R, S, Y, and L in a 3:1:1:1:1:1 ratio; and the third residue of HC CDR3 varies among H, D, R, S, Y, and L in a 3:1:1:1:1:1 ratio; or (ii) the first residue of HC CDR3 varies among T, Y, R, D, and L in a 5:1:1:1:1 ratio; the second residue of HC CDR3 varies among T, Y, R, D, and L in a 5:1:1:1:1 ratio; and the third residue of HC CDR3 varies among G, S, Y, R, D, and L in a 5:1:1:1:1:1 ratio.

[0058] These embodiments of the present invention, other embodiments, and their features and characteristics will be apparent from the description, drawings, and claims that follow.

DETAILED DESCRIPTION

5 [0059] Antibodies ("Ab") concentrate their diversity into those regions that are involved in determining affinity and specificity of the Ab for particular targets. These regions may be diverse in sequence or in length. Generally, they are diverse in both ways. However, within families of human antibodies the diversities, both in sequence and in length, are not truly random. Rather, some amino acid residues are preferred at certain positions of the CDRs and
10 some CDR lengths are preferred. These preferred diversities account for the natural diversity of the antibody family.

[0060] According to this invention, and as more fully described below, libraries of vectors and genetic packages that encode members of a diverse family of human antibodies comprising heavy chain (HC) CDR3s that are between about 3 to about 35 amino acids in length may be
15 prepared and used. The HC CDR3s may also, in certain embodiments, may be rich in Y and S and/or comprise diversified D regions. Also provided are focused libraries comprising such HC CDR3s.

[0061] When an immune cell constructs an antibody heavy chain, it connects a V segment to a D segment and that to a J segment. The D segment is optional and about 50% of human Abs have recognizable Ds. The cell may perform considerable editing at the junction sites (V-to-D, D-to-
20 J, or V-to-J) both removing and adding bases, but not exactly randomly. The initially rearranged antibody is presented on the surface of the cell and if it binds an antigen (Ag), the cell is stimulated to perform somatic mutations to improve the affinity. There are hot spots encoded in the immunoglobulin germline genes so that certain places in the Ab gene are very likely to go
25 through a particular set of mutations in search of a better binder to a persistent Ag. In nature, some of the mutations are in framework positions but most are in the complementarity determining regions (CDRs). Of particular interest is the CDR3 of the heavy chain (HC) because it shows not only a high degree of sequence diversity but also length diversity. Antibody (Ab) libraries have been built in which the CDRs are replaced with random DNA, and useful Abs
30 have been obtained. However, some therapeutic Abs show a significant degree of antigenicity. It is possible that Abs that are closer to human germline would be less antigenic.

[0062] Definitions

[0063] For convenience, before further description of the present invention, certain terms employed in the specification, examples and appended claims are defined here.

5 **[0064]** The singular forms “a”, “an”, and “the” include plural references unless the context clearly dictates otherwise.

[0065] The term “affinity” or “binding affinity” refers to the apparent association constant or K_A . The K_A is the reciprocal of the dissociation constant (K_D). A binding protein may, for example, have a binding affinity of at least 10^5 , 10^6 , 10^7 , 10^8 , 10^9 , 10^{10} and 10^{11} M^{-1} for a particular target molecule. Higher affinity binding of a binding protein to a first target relative to a second target can be indicated by a higher K_A (or a smaller numerical value K_D) for binding the first target than the K_A (or numerical value K_D) for binding the second target. In such cases, the binding protein has specificity for the first target (e.g., a protein in a first conformation or mimic thereof) relative to the second target (e.g., the same protein in a second conformation or mimic thereof; or
10 a second protein). Differences in binding affinity (e.g., for specificity or other comparisons) can be at least 1.5, 2, 3, 4, 5, 10, 15, 20, 37.5, 50, 70, 80, 91, 100, 500, 1000, or 10^5 fold.

[0066] Binding affinity can be determined by a variety of methods including equilibrium dialysis, equilibrium binding, gel filtration, ELISA, surface plasmon resonance, or spectroscopy (e.g., using a fluorescence assay). Exemplary conditions for evaluating binding affinity are in
20 TRIS-buffer (50mM TRIS, 150mM NaCl, 5mM $CaCl_2$ at pH7.5). These techniques can be used to measure the concentration of bound and free binding protein as a function of binding protein (or target) concentration. The concentration of bound binding protein ([Bound]) is related to the concentration of free binding protein ([Free]) and the concentration of binding sites for the binding protein on the target where (N) is the number of binding sites per target molecule by the
25 following equation:

$$[Bound] = N \cdot [Free] / ((1/K_A) + [Free]).$$

[0067] It is not always necessary to make an exact determination of K_A , though, since sometimes it is sufficient to obtain a quantitative measurement of affinity, e.g., determined using a method such as ELISA or FACS analysis, is proportional to K_A , and thus can be used for comparisons,
30 such as determining whether a higher affinity is, e.g., 2-fold higher, to obtain a qualitative measurement of affinity, or to obtain an inference of affinity, e.g., by activity in a functional

assay, e.g., an *in vitro* or *in vivo* assay.

[0068] The term “antibody” refers to a protein that includes at least one immunoglobulin variable domain or immunoglobulin variable domain sequence. For example, an antibody can include a heavy (H) chain variable region (abbreviated herein as VH), and a light (L) chain variable region (abbreviated herein as VL). In another example, an antibody includes two heavy (H) chain variable regions and two light (L) chain variable regions. Heavy chain and light chain may also be abbreviated as HC and LC, respectively. The term “antibody” encompasses antigen-binding fragments of antibodies (e.g., single chain antibodies, Fab and sFab fragments, F(ab')₂, Fd fragments, Fv fragments, scFv, and domain antibodies (dAb) fragments (de Wildt et al., Eur J Immunol. 1996; 26(3):629-39.)) as well as complete antibodies. An antibody can have the structural features of IgA, IgG, IgE, IgD, IgM (as well as subtypes thereof). Antibodies may be from any source, but primate (human and non-human primate) and primatized are preferred.

[0069] The VH and VL regions can be further subdivided into regions of hypervariability, termed “complementarity determining regions” (“CDR”), interspersed with regions that are more conserved, termed “framework regions” (“FR”). The extent of the framework region and CDRs has been precisely defined (see, Kabat, E.A., et al. (1991) *Sequences of Proteins of Immunological Interest, Fifth Edition*, U.S. Department of Health and Human Services, NIH Publication No. 91-3242, and Chothia, C. et al. (1987) *J. Mol. Biol.* 196:901-917, see also www.hgmp.mrc.ac.uk). Kabat definitions are used herein. Each VH and VL is typically composed of three CDRs and four FRs, arranged from amino-terminus to carboxy-terminus in the following order: FR1, CDR1, FR2, CDR2, FR3, CDR3, FR4.

[0070] The VH or VL chain of the antibody can further include all or part of a heavy or light chain constant region, to thereby form a heavy or light immunoglobulin chain, respectively. In one embodiment, the antibody is a tetramer of two heavy immunoglobulin chains and two light immunoglobulin chains, wherein the heavy and light immunoglobulin chains are inter-connected by, e.g., disulfide bonds. In IgGs, the heavy chain constant region includes three immunoglobulin domains, CH1, CH2 and CH3. The light chain constant region includes a CL domain. The variable region of the heavy and light chains contains a binding domain that interacts with an antigen. The constant regions of the antibodies typically mediate the binding of the antibody to host tissues or factors, including various cells of the immune system (e.g., effector cells) and the first component (C1q) of the classical complement system. The light

chains of the immunoglobulin may be of types, kappa or lambda. In one embodiment, the antibody is glycosylated. An antibody can be functional for antibody-dependent cytotoxicity and/or complement-mediated cytotoxicity.

5 [0071] One or more regions of an antibody can be human or effectively human. For example, one or more of the variable regions can be human or effectively human. For example, one or more of the CDRs can be human, e.g., HC CDR1, HC CDR2, HC CDR3, LC CDR1, LC CDR2, and LC CDR3. Each of the light chain CDRs can be human. HC CDR3 can be human. One or more of the framework regions can be human, e.g., FR1, FR2, FR3, and FR4 of the HC or LC. For example, the Fc region can be human. In one embodiment, all the framework regions are
10 human, e.g., derived from a human somatic cell, e.g., a hematopoietic cell that produces immunoglobulins or a non-hematopoietic cell. In one embodiment, the human sequences are germline sequences, e.g., encoded by a germline nucleic acid. In one embodiment, the framework (FR) residues of a selected Fab can be converted to the amino-acid type of the corresponding residue in the most similar primate germline gene, especially the human germline gene. One or more of the constant regions can be human or effectively human. For example, at
15 least 70, 75, 80, 85, 90, 92, 95, 98, or 100% of an immunoglobulin variable domain, the constant region, the constant domains (CH1, CH2, CH3, CL), or the entire antibody can be human or effectively human.

[0072] All or part of an antibody can be encoded by an immunoglobulin gene or a segment
20 thereof. Exemplary human immunoglobulin genes include the kappa, lambda, alpha (IgA1 and IgA2), gamma (IgG1, IgG2, IgG3, IgG4), delta, epsilon and mu constant region genes, as well as the many immunoglobulin variable region genes. Full-length immunoglobulin "light chains" (about 25 KDa or about 214 amino acids) are encoded by a variable region gene at the NH2-terminus (about 110 amino acids) and a kappa or lambda constant region gene at the COOH--
25 terminus. Full-length immunoglobulin "heavy chains" (about 50 KDa or about 446 amino acids), are similarly encoded by a variable region gene (about 116 amino acids) and one of the other aforementioned constant region genes, e.g., gamma (encoding about 330 amino acids). The length of human HC varies considerably because HC CDR3 varies from about 3 amino-acid residues to over 35 amino-acid residues.

30 [0073] Herein, the terms "D segment" and "D region" are used interchangeably and are identical. It is to be understood that these items have both DNA and amino-acid representations and that

which is meant is clear from the context.

[0074] A “library” or “display library” refers to a collection of nucleotide, e.g., DNA, sequences within clones; or a genetically diverse collection of polypeptides displayed on replicable display packages capable of selection or screening to provide an individual polypeptide or a mixed population of polypeptides.

[0075] The term “package” as used herein refers to a replicable genetic display package in which the particle is displaying a polypeptide at its surface. The package may be a bacteriophage which displays an antigen binding domain at its surface. This type of package has been called a phage antibody (pAb).

[0076] A “pre-determined target” refers to a target molecule whose identity is known prior to using it in any of the disclosed methods.

[0077] The term “replicable display package” as used herein refers to a biological particle which has genetic information providing the particle with the ability to replicate. The particle can display on its surface at least part of a polypeptide. The polypeptide can be encoded by genetic information native to the particle and/or artificially placed into the particle or an ancestor of it. The displayed polypeptide may be any member of a specific binding pair e.g., heavy or light chain domains based on an immunoglobulin molecule, an enzyme or a receptor etc. The particle may be, for example, a virus e.g., a bacteriophage such as fd or M13.

[0078] The term “vector” refers to a DNA molecule, capable of replication in a host organism, into which a gene is inserted to construct a recombinant DNA molecule. A “phage vector” is a vector derived by modification of a phage genome, containing an origin of replication for a bacteriophage, but not one for a plasmid. A “phagemid vector” is a vector derived by modification of a plasmid genome, containing an origin of replication for a bacteriophage as well as the plasmid origin of replication.

[0079] In discussing oligonucleotides, the notation “[RC]” indicates that the Reverse Complement of the oligonucleotide shown is the one to be used.

[0080] Human Antibody Heavy Chain CDR3s

[0081] The heavy chain (“HC”) Germ-Line Gene (GLG) 3-23 (also known as VP-47) accounts for about 12% of all human Abs and is preferred as the framework in the preferred embodiment of the invention. It should, however, be understood that other well-known frameworks, such as

4-34, 3-30, 3-30.3 and 4-30.1, may also be used without departing from the principles of the focused diversities of this invention.

[0082] In addition, JH4 (YEDYW₁₀₃GQGTLVTVSS (SEQ ID NO:1)) occurs more often than JH3 in native antibodies. Hence, it is preferred for the focused libraries of this invention.

5 However, JH3 (AFDIW₁₀₃GQGTMVTVSS (SEQ ID NO:2)), JH6 (YYYYYGMDYW₁₀₃GQGTTVTVSS (SEQ ID NO:3)), JH1, JH2, or JH5 could be used as well. JH2 has the advantage of having RG at 105-106 instead of QG in all the other human JHs. JH3 has the disadvantage of M₁₀₈. In a collection of 1419 Abs that were ELISA positive for at least one target, we saw 17 JH1s, 31 JH2s, 452 JH3s, 636 JH4s, 32 JH5s, and 251 JH6s. If
10 present, the double underscored portions of the JHs are considered to be part of CDR3. In Table 3, the FR4 parts of the JHs are underscored.

[0083] The frequency at which each amino-acid appeared in the HC CDR3s of these 1419 Abs was tabulated and recorded in Table 75. Note that the most common amino acid is Tyr with Gly, Asp, Ser, and Arg following in that order. Rel. Up is the relative abundance of each type
15 compared to Cys, the least common. Rel. Down is the abundance of each type compared to Tyr, the most common. Hence the preferred amino-acid types to substitute into HC CDR3s are Y, G, D, S, and R.

[0084] Naturally, HC CDR3s vary in length. About half of human HCs consist of the components: V::nz::D::ny::JHn where V is a V gene, nz is a series of bases that are essentially
20 random, D is a D segment, often with heavy editing at both ends, ny is a series of bases that are essentially random, and JHn is one of the six JH segments, often with heavy editing at the 5' end. The D segments appear to provide spacer segments that allow folding of the IgG. The greatest diversity is at the junctions of V with D and of D with JH.

[0085] Corbett et al. (Corbett SJ, Tomlinson IM, Sonnhhammer EL, Buck D, Winter G. *J Mol Biol.* 1997 V270:587-97.) showed that the human immune system does not insert multiple D
25 segments and recombining D segments. Nevertheless, D segments have been selected to be good components of HC CDR3s and the present invention comprises HC CDR3 that contain more than one D segment.

[0086] Human D segments have some very strong biases. The tally of the 522 amino-acids in
30 human D segments is Y 70 (13.4%), L 63 (12.1%), V 52 (10%), G 49 (9.4%), I 41 (7.9%), T 40 (7.7%), S 33 (6.3%), W 27 (5.2%), D 21 (4%), A 19 (3.6%), R 16 (3.1%), TAG 15 (2.9%), N 14

2.7%), Q 11 (2.1%), C 9 (1.7%), E 9 (1.7%), F 8 (1.5%), M 8 (1.5%), TGA 8 (1.5%), TAA 7 (1.3%), P 1 (0.2%), H 1 (0.2%), and K 0 (0%). There is one D (2-8 RF 1) that has an unpaired Cys but also a TGA stop codon, so it is little used. Thus, D segments are primarily hydrophobic. The frequencies of amino acids in human HC CDR3s are shown in Table 75. There are both

5 similarities and differences in the frequencies. In HC CDR3s overall, Tyr is the most common and only Gly comes close (96% as common as Tyr). Asp (75% as common as Tyr), Ser (53% as common as Tyr). Leu, Val, and Ile are relatively common in the D segments if all the D segments are counted as equal. The immune system does not use the D segments with equal frequency. Table 77 shows the frequency of utilization of D segments. The D segments that are

10 often used are very rich in Tyr, Gly, Ser, and Asp. Arg is not found in the most often used D segments nor is Arg encoded in any of the CDR portions of JH segments. Arg comes to prominence either by mutation of V, D, and J or in the filler regions between V and D, D and J, or V and J. In this sample, 50% of all the amino acids are Tyr, Gly, Asp, Ser, or Arg. In one embodiment of the present invention, substitutions of "parental" HC CDR3 sequences is limited

15 to the set of amino acids consisting of Tyr, Gly, Ser, Asp, and Arg. In one embodiment of the present invention, Arg is made common in the filler regions between V and D, between D and J, or between V and J.

[0087] In the preferred libraries of this invention, both types of HC CDR3s are used. In HC CDR3s that have no identifiable D segment, the structure is V::nz::JH_n (n=1,6) where JH is

20 usually edited at the 5' end. In HC CDR3s that have an identifiable D segment, the structure is V::nz::D::ny::JH_n.

[0088] Provided herein are HC CDR3s that are between about 3 to a about 35 amino acids in length. The HC CDR3s may also, in certain embodiments, be rich in Y and S and/or comprise diversified D regions, where a D region is present. For example, the HC CDR3s may contain

25 between about 43% and about 80% Y and/or S residues, e.g., about 43%, about 48%, about 69%, about 63%, about 71%, about 62%, about 58%, about 68%, about 80%, about 77%, or greater than about 40%, or about 40% to less than about 100%, of the residues are Y and/or S. For example, not all of the residues in the CDR3 are Y and/or S. The HC CDR3s may, in certain embodiments, comprise an extended JH region. Exemplary HC CDR3 component designs of the

30 preferred libraries of this invention are shown and described in Examples 1, 2, and 3.

[0089] In some embodiments, diversity (e.g., in a CDR, e.g., HC CDR3, or framework region (e.g., framework region near or adjacent to a CDR, e.g., CDR3, e.g., HC CDR3) is generated to create on average about 1, about 2, about 3, about 4, about 5, about 6, about 7, about 8, about 9, about 10, or about 1 to about 10 mutations (e.g., base change), e.g., per CDR (e.g., HC CDR3) or framework region (e.g., framework region near or adjacent to a CDR, e.g., CDR3, e.g., HC CDR3). In some implementations, the mutagenesis is targeted to regions known or likely to be at the binding interface. Further, mutagenesis can be directed to framework regions near or adjacent to the CDRs. In the case of antibodies, mutagenesis can also be limited to one or a few of the CDRs, e.g., to make precise step-wise improvements. Likewise, if the identified ligands are enzymes, mutagenesis can provide antibodies that are able to bind to the active site and vicinity. The CDR or framework region (e.g., an HC CDR3 described herein) may be, in certain embodiments, subjected to error-prone PCR to generate the diversity. This approach uses a "sloppy" version of PCR, in which the polymerase has a fairly high error rate (up to 2%), to amplify the wild-type sequence, and is generally described in Pritchard, et al. (2005) *J. Theor. Biol.* 234: 497-509 and Leung et al. (1989) *Technique* 1:11-15. Other exemplary mutagenesis techniques include DNA shuffling using random cleavage (Stemmer (1994) *Nature* 389-391; termed "nucleic acid shuffling"), RACHITTTM (Coco et al. (2001) *Nature Biotech.* 19:354), site-directed mutagenesis (Zoller et al. (1987) *Nucl Acids Res* 10:6487-6504), cassette mutagenesis (Reidhaar-Olson (1991) *Methods Enzymol.* 208:564-586) and incorporation of degenerate oligonucleotides (Griffiths et al. (1994) *EMBO J.* 13:3245).

[0090] In some embodiments of the invention, D segments in which a majority of the residues are either Ser or Tyr are picked. In some embodiments, when the DNA encoding the D region is synthesized, each Ser or Tyr residue is encoded by TMT, TMC, or TMY so that the encoded amino acid is either Ser or Tyr.

[0091] In some embodiments, the HC CDR3 sequences described herein may be subjected to selection for open reading frames by fusing the sequence encoding the HC CDR3 of interest in frame to an antibiotic resistance gene, such as *Kan^R* gene and selecting for kanamycin resistance. Cells in which the potential CDR3 has a stop codon or a frame shift will not have the antibiotic resistance and that sequence will be eliminated.

[0092] Methods of Construction of Libraries comprising Human Antibody Heavy Chain CDR3s and Libraries comprising Human Antibody Heavy Chain CDR3s

[0093] An antibody library is a collection of proteins that include proteins that have at least one immunoglobulin variable domain sequence. For example, camelized variable domains (e.g., VH domains) can be used as a scaffold for a library of proteins that include only one immunoglobulin variable domain sequence. In another example, the proteins include two variable domains sequences, e.g., a VH and VL domain, that are able to pair. An antibody library can be prepared from a nucleic acid library (an antibody-coding library) that includes antibody-coding sequences, e.g., comprising the sequences encoding the HC CDR3s provided herein.

[0094] In cases where a display library is used, each member of the antibody-coding library can be associated with the antibody that it encodes. In the case of phage display, the antibody protein is physically associated (directly or indirectly) with a phage coat protein. A typical antibody display library member displays a polypeptide that includes a VH domain and a VL domain. The display library member can display the antibody as a Fab fragment (e.g., using two polypeptide chains) or a single chain Fv (e.g., using a single polypeptide chain). Other formats can also be used.

[0095] As in the case of the Fab and other formats, the displayed antibody can include one or more constant regions as part of a light and/or heavy chain. In one embodiment, each chain includes one constant region, e.g., as in the case of a Fab. In other embodiments, additional constant regions are included. It is also possible to add one or more constant regions to a molecule after it is identified as having useful antigen binding site. See, e.g., US 2003-0224408.

[0096] Antibody libraries can be constructed by a number of processes (see, e.g., de Haard et al. (1999) *J. Biol. Chem* 274:18218-30; Hoogenboom et al. (1998) *Immunotechnology* 4:1-20, Hoogenboom et al. (2000) *Immunol Today* 21:371-8, and Hoet et al. (2005) *Nat Biotechnol.* 23(3):344-8.

[0097] In certain embodiments for constructing libraries, the heavy chains comprising the CDR3s described herein and the kappa and lambda light chains are best constructed in separate vectors. First, a synthetic gene is designed to embody each of the synthetic variable domains. The light chains may be bounded by restriction sites for ApaLI (positioned at the very end of the signal sequence) and AscI (positioned after the stop codon). The heavy chain may be bounded

by SfiI (positioned within the PeIB signal sequence) and NotI (positioned in the linker between CH1 and the anchor protein). Signal sequences other than PeIB may also be used, e.g., a M13 pIII signal sequence.

[0098] The initial genes may be made with “stuffer” sequences in place of the desired CDRs. A “stuffer” is a sequence that is to be cut away and replaced by diverse DNA, but which does not allow expression of a functional antibody gene. For example, the stuffer may contain several stop codons and restriction sites that will not occur in the correct finished library vector. Stuffers are used to avoid have any one CDR sequence highly represented.

[0099] In another embodiment of the present invention, the heavy chain and the kappa or lambda light chains are constructed in a single vector or genetic packages (e.g., for display or display and expression) having appropriate restriction sites that allow cloning of these chains. The processes to construct such vectors are well known and widely used in the art. Preferably, a heavy chain and kappa light chain library and a heavy chain and lambda light chain library would be prepared separately.

[00100] Most preferably, the display is on the surface of a derivative of M13 phage. The most preferred vector contains all the genes of M13, an antibiotic resistance gene, and the display cassette. The preferred vector is provided with restriction sites that allow introduction and excision of members of the diverse family of genes, as cassettes. The preferred vector is stable against rearrangement under the growth conditions used to amplify phage.

[00101] In another embodiment of this invention, the diversity captured by the methods of the present invention may be displayed and/or expressed in a phagemid vector (e.g., pMID21 (DNA sequence shown in Table 35)) that displays and/or expresses the peptide, polypeptide or protein. Such vectors may also be used to store the diversity for subsequent display and/or expression using other vectors or phage.

[00102] In still other embodiments, a method termed the Rapid Optimization of Light Chains or “ROLIC”, described in U.S.S.N. 61/028,265 filed February 13, 2008, U.S.S.N. 61/043,938 filed April 10, 2008, and U.S.S.N. 12/371,000 filed February 13, 2009, a large population of LCs is placed in a phage vector that causes them to be displayed on phage. A small population (e.g., 3, 10, or 25) of HCs are cloned into *E. coli* so that the HCs are secreted into the periplasm, e.g., those HCs having the CDR3s described herein. The *E. coli* are then

infected with the phage vectors encoding the large population of LCs to produce the HC/LC protein pairings on the phage. The phage particles carry only a LC gene.

[00103] In another aspect, in a method termed the Economical Selection of Heavy Chains or "ESCH", also described in U.S.S.N 61/028,265 filed February 13, 2008, U.S.S.N. 61/043,938 filed April 10, 2008, and U.S.S.N. 12/371,000 filed February 13, 2009, a small population of LCs may be placed in a vector that causes them to be secreted. A new library of HCs in phage is constructed, such as those provided herein comprising the CDR3s. The LCs and HCs can then be combined by the much more efficient method of infection. Once a small set of effective HC are selected, these can be used as is, fed into ROLIC to obtain an optimal HC/LC pairing, or cloned into a Fab library of LCs for classical selection.

[00104] In another embodiment of this invention, the diversity captured by the methods of the present invention may be displayed and/or expressed using a vector suitable for expression in a eukaryotic cell, e.g., a yeast vector, e.g., for expression in a yeast cell.

[00105] Other types of protein display include cell-based display (see, e.g., WO 03/029,456); ribosome display (see, e.g., Mattheakis et al. (1994) *Proc. Natl. Acad. Sci. USA* 91:9022 and Hanes et al. (2000) *Nat Biotechnol.* 18:1287-92); protein-nucleic acid fusions (see, e.g., U.S. Pat. No. 6,207,446); and immobilization to a non-biological tag (see, e.g., U.S. Pat. No. 5,874,214).

[00106] Antibodies isolated from the libraries of the present disclosure may be analyzed to determine the type of the LC and the closest germline gene. In a preferred embodiment, non-germline framework residues are changed back to the germline amino acid so long as binding affinity and specificity are not adversely affected to an unacceptable extent. The substitutions may be done as a group or singly. Human germline sequences are disclosed in Tomlinson, I.A. et al., 1992, *J. Mol. Biol.* 227:776-798; Cook, G. P. et al., 1995, *Immunol. Today* 16 (5): 237-242; Chothia, D. et al., 1992, *J. Mol. Bio.* 227:799-817. The V BASE directory provides a comprehensive directory of human immunoglobulin variable region sequences (compiled by Tomlinson, I.A. et al. MRC Centre for Protein Engineering, Cambridge, UK). Antibodies are "germlined" by reverting one or more non-germline amino acids in framework regions to corresponding germline amino acids of the antibody, so long as binding properties are substantially retained. Similar methods can also be used in the constant region, e.g., in constant immunoglobulin domains.

[00107] For example, an antibody can include one, two, three, or more amino acid substitutions, e.g., in a framework, CDR, or constant region, to make it more similar to a reference germline sequence. One exemplary germlining method can include identifying one or more germline sequences that are similar (e.g., most similar in a particular database) to the sequence of the isolated antibody. Mutations (at the amino acid level) are then made in the isolated antibody, either incrementally or in combination with other mutations. For example, a nucleic acid library that includes sequences encoding some or all possible germline mutations is made. The mutated antibodies are then evaluated, e.g., to identify an antibody that has one or more additional germline residues relative to the isolated antibody and that is still useful (e.g., has a functional activity). In one embodiment, as many germline residues are introduced into an isolated antibody as possible.

[00108] In one embodiment, mutagenesis is used to substitute or insert one or more germline residues into a framework and/or constant region. For example, a germline framework and/or constant region residue can be from a germline sequence that is similar (e.g., most similar) to the non-variable region being modified. After mutagenesis, activity (e.g., binding or other functional activity) of the antibody can be evaluated to determine if the germline residue or residues are tolerated (i.e., do not abrogate activity). Similar mutagenesis can be performed in the framework regions.

[00109] Selecting a germline sequence can be performed in different ways. For example, a germline sequence can be selected if it meets a predetermined criteria for selectivity or similarity, e.g., at least a certain percentage identity, e.g., at least 75, 80, 85, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, or 99.5% identity. The selection can be performed using at least 2, 3, 5, or 10 germline sequences. In the case of CDR1 and CDR2, identifying a similar germline sequence can include selecting one such sequence. In the case of CDR3, identifying a similar germline sequence can include selecting one such sequence, but may include using two germline sequences that separately contribute to the amino-terminal portion and the carboxy-terminal portion. In other implementations, more than one or two germline sequences are used, e.g., to form a consensus sequence.

[00110] CDR1, CDR2, and light-chain diversity

[00111] It is to be understood that the libraries of HC CDR3 are constructed in the background of diversity in HC CDR1, HC CDR2, and light chains. The light-chain diversity may be encoded in the same DNA molecule as the HC diversity or the LC and HC diversities may be encoded in separate DNA molecules. In Table 22 the fusion of a signal sequence::

VH::CH1::His6::Myc::IIIstump. CDR1 comprises residues 31-35; there is diversity at residues 31, 33, and 35. In one embodiment, residues 31, 33, and 35 can be any amino-acid type except cysteine. CDR2 comprises residues 50 through 65. There is diversity at positions 50, 52, 52a, 56, and 58. In one embodiment, residues 50, and 52 can be any of the types Ser, Gly, Val, Trp, Arg, Tyr; residue 52a can be Pro or Ser and residues 56 and 58 can be any amino-acid type except Cys. The diversity of HC CDR3 is cloned into a diversity of HC CDR1 and 2 that is at least 1. E 4, 1. E 5, 1. E 6, 1. E 7, 5. E 7, or 1. E 8.

[00112] In one embodiment, residues 31, 33, 35, 50, 52, 56, and 58 can be any amino-acid type except Cys or Met and residue 52a can be Gly, Ser, Pro, or Tyr. The diversity of HC CDR3 is cloned into a diversity of HC CDR1 and 2 that is at least 1. E 4, 1. E 5, 1. E 6, 1. E 7, 5. E 7, or 1. E 8.

[00113] In one embodiment, the diversity of the HC is cloned into a vector (phage or phagemid) that contains a diversity of light chains. This diversity is at least 25, 50, 100, 500, 1. E 3, 1. E 4, 1. E 5, 1. E 6, or 1. E 7. The diversity of HC CDR3 is at least 221, 272, 500, 1000, 1. E 4, 1. E 5, 1. E 6, 1. E 7, 1. E 8, or 1. E 9.

[00114] In one embodiment, the diversity of the HC is cloned into a phage vector that displays the HC on a phage protein such as III, VIII, VII, VI, or IX or a fragment of one of these sufficient to cause display and light chains are combined with the HC by infecting a cell collection wherein each cell secretes a light chain. The diversity of the light chains in the cells is at least 5, 10, 15, 20, 25, 30, 35, 40, 50, 75, or 100. The diversity of HC CDR3 is at least 221, 272, 500, 1000, 1. E 4, 1. E 5, 1. E 6, 1. E 7, 1. E 8, or 1. E 9.

[00115] Table 30 shows the sequence of the phage vector DY3FHC87 (SEQ ID NO:894) which carries a *bla* gene, a display cassette for heavy chains under control of a P_{lac} promoter. DY3FHC87 contains all the genes of M13 as well. Infecting F+ *E. coli* cells that harbor a diversity of light chains in a vector such as pLCSK23 (Sequence in Table 40) (SEQ ID NO:896). The vector pLCSK23 carries a *Kan^R* gene. Under the control of P_{lac} promoter, there is a gene

beginning at base 2215 having a signal sequence (bases 2215-2277), a VL (in this sequence the VL encodes the sequence shown in (SEQ ID NO:897) from base 2278 to base 2598, Ckappa from base 2599 to 2922, a linker that allows an NotI site from 2923 to 2931, and a V5 tag (bases 2932-2973). There are an SfiI site at 2259-2271 and a KpnI site at 2602-2605 to allow easy replacement of Vkappas. (SEQ ID NO:897) is an example of the proteins that are secreted. It is to be understood that CKappa and the V5 tag are constant. All of the proteins shown in Table 19 (VK1O2gl-JK3, VK1O2var1, VK1O2var2, VK1O2var3, VK1O2var4, VK1O2var5, VK3L6gl-JK4, VK3L6var1, VK3L6var2, VK3L6var3, VK3L6var4, VK3L6var5, VK3L6var6, VK3L6var7, VK3L6var8, VK3A27gl-JK3, VK3A27var1, VK3A27var2, VK3A27var3, VK3A27var4, VK3A27var5, VK3A27var6, VK3A27var7, VK3L2gl-JK3, and VK1glL8-JK5) will have these sequences attached at the carboxy end.

[00116] Light Chain Diversity

[00117] Table 800 shows a kappa LC (light chain) that is known to pair well with 3-23 and with five CDR mutations with one HC based on 3-23, LC K1(O12)::JK1 makes a high affinity Ab to a protein target. O12 is a frequently used VKI. The gene has been designed to have useful, distinct restriction sites in the signal sequence (*Apa*LI), FR1 (*Xho*I, *Sgf*I), FR2 (*Kpn*I), FR3(*Xba*I), and Fr4::Ckappa (*Bsi*WI) so that each CDR and be replaced with a varied population.

[00118] In human LCs, CDR3 is most important and CDR1 is next most important. CDR2 seldom makes contact with the Ag. Diversity is introduced into the CDRs as shown in Table 900 and Table 1000 (CDR1), Table 1100 and Table 1200 (CDR2), Tables 1300, 1400, and 1500 (CDR3). For Economical Selection of Heavy Chains (ESHC), a small number, for example, 50 LCs with diversity in CDR3 as in Table 1200 are picked for expression in pLCSK24 for secretion into the periplasm. More LCs can be used if several cell lines are maintained so that each cell line contains, for example, 50 or fewer LC.

[00119] Table 900 shows diversity for LC CDR1. The library can contain the O12 residue with the added diversity of the AA types shown as "allowed"; reading "allowed" as "additional allowed types" in Tables 900, 1000, 1100, 1200, 1300, 1400. O12 has R₂₄ASQSISSYLN₃₄. Other VKI loci have Q at 24. Other loci have M at 25. S₂₆ and Q₂₇ are invariant in VKI. Other VKI loci have D or G at 28. I₂₉ and L₃₃ are invariant in VKI and the side groups are oriented.

inward. Other VKI loci allow the diversity shown in Table 900 at positions 30, 31, 32, and 34. In Table 900, only seven of the eleven positions are varied and the total diversity is 576.

[00120] Table 1000 shows a higher level of diversity for LC CDR1. Here 8 of 11 positions have been varied. Those that are constant are either far from the combining site or have buried side groups.

[00121] Table 1100 shows a low level variegation for CDR2. CDR2 is far from the antigen combining site and diversity here may not be very useful. Indeed, the GL diversity is very limited. Table 1100 includes the GL diversity. Table 1200 contains a higher level of diversity, 1920 sequences allowed.

10 [00122] Table 1300 shows a low level of diversity for LC CDR3, 2160 sequences. Table 1400 shows a higher level which allows 105,840 sequences.

[00123] For ROLIC, about 3×10^7 LC are produced having the diversity shown in Tables 900, 1100, and 1300.

15 [00124] **Heavy Chain Diversity**

[00125] Ab HC (heavy chain) have diversity in CDR1, CDR2, and CDR3. The diversity in CDR3 is especially complex because there is both sequence and length diversity. The sequence diversity is not random. Cells making Ab genes join a V segment to a D segment to a JH segment. The D segment is optional; about half of natural human Abs have a recognizable D. There can be extensive editing at the V-D, D-J, or V-J boundaries with none to many bases added or removed. An Ab that has a germline V::D::JH could be viewed as a germline Ab.

20 [00126] Human D segments are shown in Table 21. Each germline (GL) D segment may appear in an Ab gene in any of the three forward reading frames. In some reading frames, some of the D segments encode stop codons. These D segments do occur rarely with the stop codon modified. Table 600 shows the frequency of each D segment as a percent of all observed D segments. Most of the examples herein that contain D segments use Ds that are fairly common (>2% of all observed Ds).

25 [00127] In one aspect, the present invention involves composing Ab HC genes by fusing 3-23 (or another VH, such as 4-34) to one of a) a number of amino acids picked from the set comprising (S, Y, D, R, N), b) a D region, c) a JH region, and d) the FR4 portion of a JH region. 30 These fusions can be a GL 3-23 or a 3-23 that has synthetic diversity in CDR1 and/or CDR2.

The lengths of the HC CDR3 and be any number from about 3 to about 24. Preferably, the library would contain member with HC CDR3 of lengths 6, 8, 10, 12, 14, 16, 18, and 20. Alternatively, the lengths could be 5, 8, 11, 14, 17, and 20 or any other combination.

[00128] Table 21 shows a number of examples of designs of suitable CDR3s with lengths from 6 to 20. The codons that specify the uppercase letters in column 2 are to be synthesized with wobbling. Column 3 shows the level of doping. Table 100 shows ratios in which the various lengths of HC CDR3 could be combined to form a library that is expected to contain Abs that bind almost all protein targets.

Table 100							
Length	6	8	10	12	14	16	20
Diversity	1. x 10 ⁵	2. x 10 ⁵	4. x 10 ⁵	8. x 10 ⁵	8. x 10 ⁵	8. x 10 ⁵	4. x 10 ⁵

10 [00129] For length 6, Table 21 four examples are given. For example, 6a has VH(3-23) joined directly to JH1 with the first six AAs wobbled, 6b has Tyr joined to D4-17 in second reading frame joined to the FR4 AAs of JH1, and 6c has D5-5(3) joined to the FR residues of JH1. Since these give different kinds of diversity, including all is preferred, but a library containing only one of these should give useful Abs.

15 [00130] For length 8, Table 21 shows three examples. 8a has YY fused to all of JH1 while 8b has one Y fused to D6-13(1) fused to the FR region of JH1. Lengths 10, 12, 14, 16, and 20 are also shown in Table 21. The HC CDR3 diversity could be built in a germline 3-23 or 3-23 containing synthetic diversity. Alternatively, a different VH, such as 4-34 could be used.

[00131] ROLIC is a method in which a small population of HCs are expressed in F⁺ *E. coli* as soluble proteins. The population is infected with phage that carry LC::III_{stump} fusions. The phage produced obtain a HC from the periplasm of the cell that produces them. These phage can be bound to immobilized target and the binder are separated from the non-binders. The size of the population is important because when the recovered phage are propagated, the recovered phage must find the same type of cell as it came from to continue the association between LC and HC. Thus it is desirable that the number of HC be small in each cell line. Thus it may be desirable to maintain a number of cell lines with up to 10, 20, 30, or 40 different HC in each cell line. Thus we may have 1, 2, 4, 6, 8, 10, 24, 48, or 96 cell lines and we perform the same number of parallel phage productions, selections, and amplifications. After one or two rounds,

we test colonies for production of phage that bind the target by an ELISA assay. Each ELISA⁺ colony contains a useful LC and a useful HC, but they are not on the same piece of DNA.

Nevertheless, we know the start and end of each LC and each HC and can therefore use PCR on the colony to produce a Fab display or Fab secretion cassette that can be put into a display phage or phagemid or into a Fab-production plasmid.

[00132] In Efficient Selection of HCs (ESHC), we reverse the roles of LC and HC in ROLIC and have LCs in a plasmid so that they are produced as soluble proteins in the periplasm of F⁺ *E. coli*. We produce the HC diversity in a phage vector that has no LC gene. We infect the LC-producing F⁺ *E. coli* with the HC-carrying phage. We obtain phage that carry an HC gene and both HC and LC proteins. We select these phage for binding to the target. In many Abs, the LC is permissive and does not contribute greatly to binding affinity. Picking the best LC can greatly increase affinity, but it is usually possible to select a Fab with a very limited repertoire of LCs. Thus, we place a small set of LCs, preferable germline in the framework regions in the LC-producing F⁺ *E. coli*. If there are, for example, 25 LC in the LC cell line, then we obtain a 25-fold reduction in the number of cell transformants that need to be made.

[00133] The libraries described have a range of HC CDR3 lengths. To favor proper folding, the HC CDR3 have either a D segment or no D segment joined to most, all, or the framework portion of a JH segment. The sequences are diversified by using wobble DNA synthesis. Although this theoretically allows any amino-acid type at any position, in practice, the actual sequences are strongly biased toward the parental sequences and AA types that are close in the genetic code table.

[00134] By using ESHC, we can sample new designs of synthetic HC CDR3 diversity. In the examples given, we use a pool of, for example, 50 LCs. A library of 5×10^8 HC should perform as well as an old-style library of 2.5×10^{10} but require far less effort.

[00135] When wobbling a sequence, picking the initial codons affects the actual mixture of AAs seen in the library. Table 300 shows which amino-acid substitutions require 1, 2, or 3 base changes from each starting parental codon. For example, if we start with gct or gcc for Ala, all three stop codons require three base changes and so are rare. If using 76:8:8:8 mixtures, Ala will appear in 57% of the cases (0.76×0.76). V, G, T, P, S will each appear in about 6% and D about 3%. E, I, L, F, Y, H, N, C, and R will be down about 10-fold. M, W, Q, K, Am, Oc, and Op will be even rarer. If we started with gca, then E would replace D in needing only one base

change, but opal and ochre stops require only two base changes, which is undesirable. The preferred codons are marked with a star (*). The choice for serine is complicate our desire to have Y substitute for S with high frequency. This brings Op and Oc into the group that differ from the parent by only two bases. This problem can be overcome by cloning the HC CDR3 repertoire before an antibiotic resistance gene such as KanR or AmpR and selecting for resistance, thus eliminating the members that contain stop codons. In addition, the library can be produced in supE *E. coli* which insert Q instead of stopping.

[00136] Methods of Using the Libraries

[00137] Off-Rate Selection. Since a slow dissociation rate can be predictive of high affinity, particularly with respect to interactions between polypeptides and their targets, the methods described herein can be used to isolate ligands with a desired kinetic dissociation rate (i.e., reduced) for a binding interaction to a target.

[00138] To select for slow dissociating antibodies from a display library, the library is contacted to an immobilized target. The immobilized target is then washed with a first solution that removes non-specifically or weakly bound antibodies. Then the bound antibodies are eluted with a second solution that includes a saturating amount of free target, i.e., replicates of the target that are not attached to the particle. The free target binds to antibodies that dissociate from the target. Rebinding of the eluted antibodies is effectively prevented by the saturating amount of free target relative to the much lower concentration of immobilized target.

[00139] The second solution can have solution conditions that are substantially physiological or that are stringent (e.g., low pH, high pH, or high salt). Typically, the solution conditions of the second solution are identical to the solution conditions of the first solution. Fractions of the second solution are collected in temporal order to distinguish early from late fractions. Later fractions include antibodies that dissociate at a slower rate from the target than biomolecules in the early fractions. Further, it is also possible to recover antibodies that remain bound to the target even after extended incubation. These can either be dissociated using

chaotropic conditions or can be amplified while attached to the target. For example, phage bound to the target can be contacted to bacterial cells.

[00140] Selecting or Screening for Specificity. The display library screening methods described herein can include a selection or screening process that discards antibodies that bind to a non-target molecule. Examples of non-target molecules include, e.g., a carbohydrate molecule that differs structurally from the target molecule, e.g., a carbohydrate molecule that has a different biological property from the target molecule. In the case of a sulfated carbohydrate, a non-target may be the same carbohydrate without the sulfate or with the sulfate in a different position. In the case of a phosphopeptide, the non-target may be the same peptide without the phosphate or a different phosphopeptide.

[00141] In one implementation, a so-called "negative selection" step is used to discriminate between the target and related non-target molecule and a related, but distinct non-target molecules. The display library or a pool thereof is contacted to the non-target molecule. Members that do not bind the non-target are collected and used in subsequent selections for binding to the target molecule or even for subsequent negative selections. The negative selection step can be prior to or after selecting library members that bind to the target molecule.

[00142] In another implementation, a screening step is used. After display library members are isolated for binding to the target molecule, each isolated library member is tested for its ability to bind to a non-target molecule (e.g., a non-target listed above). For example, a high-throughput ELISA screen can be used to obtain this data. The ELISA screen can also be used to obtain quantitative data for binding of each library member to the target. The non-target and target binding data are compared (e.g., using a computer and software) to identify library members that specifically bind to the target.

[00143] In certain embodiments, the antibodies comprising the CDR3s of the invention may be able to bind carbohydrates. Methods for evaluating antibodies for carbohydrate binding include ELISA, immunohistochemistry, immunoblotting, and fluorescence-activated cell sorting. These methods can be used to identify antibodies which have a K_D of better than a threshold, e.g., better than 100 nM, 50 nM, 10 nM, 5 nM, 1 nM, 500 pM, 100 pM, or 10 pM.

[00144] ELISA. Proteins encoded by a display library can also be screened for a binding property using an ELISA assay. For example, each protein is contacted to a microtitre plate whose bottom surface has been coated with the target, e.g., a limiting amount of the target. The

plate is washed with buffer to remove non-specifically bound polypeptides. Then the amount of the protein bound to the plate is determined by probing the plate with an antibody that can recognize the polypeptide, e.g., a tag or constant portion of the polypeptide. The antibody is linked to an enzyme such as alkaline phosphatase, which produces a calorimetric product when appropriate substrates are provided. The protein can be purified from cells or assayed in a display library format, e.g., as a fusion to a filamentous bacteriophage coat. Alternatively, cells (e.g., live or fixed) that express the target molecule, e.g., a target that contains a carbohydrate moiety, can be plated in a microtitre plate and used to test the affinity of the peptides/antibodies present in the display library or obtained by selection from the display library.

10 [00145] In another version of the ELISA assay, each polypeptide of a diversity strand library is used to coat a different well of a microtitre plate. The ELISA then proceeds using a constant target molecule to query each well.

[00146] Cell Binding Assays. Antibodies can be evaluated for their ability to interact with one or more cell types, e.g., a hematopoietic cell. Fluorescent activated cell sorting (FACS) is one exemplary method for testing an interaction between a protein and a cell. The antibody is labeled directly or indirectly with a fluorophore, before or after, binding to the cells, and then cells are counted in a FACS sorter.

[00147] Other cell types can be prepared for FACS by methods known in the art.

20 [00148] Homogeneous Binding Assays. The binding interaction of candidate polypeptide with a target can be analyzed using a homogenous assay, i.e., after all components of the assay are added, additional fluid manipulations are not required. For example, fluorescence resonance energy transfer (FRET) can be used as a homogenous assay (see, for example, Lakowicz et al., U.S. Pat. No. 5,631,169; Stavrianopoulos, et al., U.S. Pat. No. 4,868,103). A fluorophore label on the first molecule (e.g., the molecule identified in the fraction) is selected such that its emitted fluorescent energy can be absorbed by a fluorescent label on a second molecule (e.g., the target) if the second molecule is in proximity to the first molecule. The fluorescent label on the second molecule fluoresces when it absorbs to the transferred energy. Since the efficiency of energy transfer between the labels is related to the distance separating the molecules, the spatial relationship between the molecules can be assessed. In a situation in which binding occurs between the molecules, the fluorescent emission of the `acceptor` molecule label in the assay should be maximal. A binding event that is configured for monitoring by FRET can be

conveniently measured through standard fluorometric detection means well known in the art (e.g., using a fluorimeter). By titrating the amount of the first or second binding molecule, a binding curve can be generated to estimate the equilibrium binding constant.

[00149] Another example of a homogenous assay is Alpha Screen (Packard Bioscience, Meriden Conn.). Alpha Screen uses two labeled beads. One bead generates singlet oxygen when excited by a laser. The other bead generates a light signal when singlet oxygen diffuses from the first bead and collides with it. The signal is only generated when the two beads are in proximity. One bead can be attached to the display library member, the other to the target. Signals are measured to determine the extent of binding.

[00150] The homogenous assays can be performed while the candidate polypeptide is attached to the display library vehicle, e.g., a bacteriophage.

[00151] Surface Plasmon Resonance (SPR). The binding interaction of a molecule isolated from a display library and a target can be analyzed using SPR. SPR or Biomolecular Interaction Analysis (BIA) detects biospecific interactions in real time, without labeling any of the interactants. Changes in the mass at the binding surface (indicative of a binding event) of the BIA chip result in alterations of the refractive index of light near the surface (the optical phenomenon of surface plasmon resonance (SPR)). The changes in the refractivity generate a detectable signal, which are measured as an indication of real-time reactions between biological molecules. Methods for using SPR are described, for example, in U.S. Pat. No. 5,641,640; Raether (1988) Surface Plasmons Springer Verlag; Sjolander and Urbaniczky (1991) Anal. Chem. 63:2338-2345; Szabo et al. (1995) Curr. Opin. Struct. Biol. 5:699-705 and on-line resources provide by BIAcore International AB (Uppsala, Sweden).

[00152] Information from SPR can be used to provide an accurate and quantitative measure of the equilibrium dissociation constant (K_D), and kinetic parameters, including k_{on} and k_{off} , for the binding of a biomolecule to a target. Such data can be used to compare different biomolecules. For example, proteins encoded by nucleic acid selected from a library of diversity strands can be compared to identify individuals that have high affinity for the target or that have a slow k_{off} . This information can also be used to develop structure-activity relationships (SAR). For example, the kinetic and equilibrium binding parameters of matured versions of a parent protein can be compared to the parameters of the parent protein. Variant amino acids at given positions can be identified that correlate with particular binding parameters, e.g., high affinity

and slow k_{off} . This information can be combined with structural modeling (e.g., using homology modeling, energy minimization, or structure determination by crystallography or NMR). As a result, an understanding of the physical interaction between the protein and its target can be formulated and used to guide other design processes.

5 [00153] Protein Arrays. Proteins identified from the display library can be immobilized on a solid support, for example, on a bead or an array. For a protein array, each of the polypeptides is immobilized at a unique address on a support. Typically, the address is a two-dimensional address. Methods of producing polypeptide arrays are described, e.g., in De Wildt et al. (2000) Nat. Biotechnol. 18:989-994; Lueking et al. (1999) Anal. Biochem. 270:103-111; Ge (2000) 10 Nucleic Acids Res. 28, e3, I-VII; MacBeath and Schreiber (2000) Science 289:1760-1763; WO 01/40803 and WO 99/51773A1. Polypeptides for the array can be spotted at high speed, e.g., using commercially available robotic apparatus, e.g., from Genetic MicroSystems or BioRobotics. The array substrate can be, for example, nitrocellulose, plastic, glass, e.g., surface-modified glass. The array can also include a porous matrix, e.g., acrylamide, agarose, or another polymer.

15

[00154] **Kits**

[00155] Also provided are kits for use in carrying out a method according to any aspect of the invention. The kits may include the necessary vectors. One such vector will typically have an origin of replication for single stranded bacteriophage and either contain the sbp member 20 nucleic acid or have a restriction site for its insertion in the 5' end region of the mature coding sequence of a phage capsid protein, and with a secretory leader coding sequence upstream of said site which directs a fusion of the capsid protein exogenous polypeptide to the periplasmic space.

[00156] Also provided are packages encoding the HC CDR3s as defined above and polypeptides comprising the HC CDR3s and fragments and derivatives thereof, obtainable by 25 use of any of the above defined methods. The derivatives may comprise polypeptides fused to another molecule such as an enzyme or a Fc tail.

[00157] The kit may include a phage vector (e.g., DY3F87HC) which has a site for insertion of HC CDR3s for expression of the encoded polypeptide in free form. The kit may also include a plasmid vector for expression of soluble light chains, e.g., pLCSK23. The kit may also 30 include a suitable cell line (e.g., TG1). The diversity of light chains encoded by pLCSK23 may be 10, 15, 20, 25, 30, or 50. The LCs in the diversity may be constructed or picked to have

certain desirable properties, such as, being germline in the framework regions and having diversity in CDR3 and/or CDR1. The germlines may be of highly utilized ones, e.g., VK1_2-O2, VK3_1-A27, VK3_5-L6, VK3_3-L2 for kappa and VL2_2a2, VL1_1c, VL1_1g, VL3_3r for lambda.

5 [00158] For example, one could clone genes for

- 25 **[00160]** The kits may include ancillary components required for carrying out the method, the nature of such components depending of course on the particular method employed. Useful ancillary components may comprise helper phage, PCR primers, buffers, and/or enzymes of various kinds. Buffers and enzymes are typically used to enable preparation of nucleotide sequences encoding Fv, scFv or Fab fragments derived from rearranged or unrearranged immunoglobulin genes according to the strategies described herein.
- [00161] METHODS OF INTRODUCING DIVERSITY**
- 30 **[00162]** There are many ways of generating DNA that is variable. One way is to use mixed-nucleotide synthesis (MNS). One version of MNS uses equimolar mixtures of nucleotides as shown in Table 5. For example, using NNK codons gives all twenty amino acids and one TAG stop codon. The distribution is 3(R/S/L): 2(A/G/V/T/P): 1(C/D/E/F/H/I/K/M/N/Q/W/Y) (e.g., 3 of each of Arg, Ser, and Leu, and so forth). An alternative, herein termed "wobbling", uses mixed nucleotides but not in equimolar amounts. For example, if a parental codon were TTC (encoding Phe), we could use a mixture of (0.082 T, 0.06 C, 0.06 A, and 0.06 G) in place of T and a mixture of (0.082 C, 0.06 T, 0.06 A, and 0.06 G) in place of C. This would give TTC or TTT (encoding Phe) 59% of the time and Leu 13%, S/V/I/C/Y ~5%, and other amino-acid types less often.
- [00163]** Van den Brulle et al. (*Biotechniques* 45:340-3 (2008)) describe a method of synthesis of variable DNA in which type II restriction enzymes are used to transfer

trinucleotides from an anchored hair-pin oligonucleotide (PHONs) to a so called “splinker”. See also EP patents 1 181 395, EP 1 411 122, EP 1 314 783 and EP applications EP 01127864.5, EP 04001462.3, EP 08006472.8. By using mixtures of anchored PHONs and splinkers, one can build libraries in which desired amino-acid types are allowed in designer-determined ratios.

5 Thus, one can direct that one amino-acid type is present, for example 82% of the time and 18 other amino-acid types (all non-parental amino-acid types except Cys) are present at 2% each. Herein, we will refer to such a synthesis as “dobbling” (digital wobbling). In some aspects, dobbling is preferred to wobbling, but wobbling provides useful embodiments, partly because the structure of the genetic code table causes wobbling to make mostly conservative substitutions.

10 Dobbling does offer the possibility to exclude unwanted amino-acid types. In CDRs, unpaired cysteines are known, even in Abs approved as therapeutics, but in some embodiments, one would like to avoid them. In some embodiments, when diversifying a D region that contains a pair of cysteines, the cysteines are not allowed to vary because the disulfide-closed loop is an important structural element and because one does not want unpaired cysteines.

15 [00164] In addition, one can synthesize a DNA molecule that encodes a parental amino-acid sequence and subject that DNA to error-prone PCR using primers that cover the framework regions so that mutations in the framework regions are avoided.

Table 5: Standard codes for mixed nucleotides

20	N is equimolar A, C, G, T	
	B is equimolar C, G, T	(not A)
	D is equimolar A, G, T	(not C)
	H is equimolar A, C, T	(not G)
	V is equimolar A, C, G	(not T)
25	K is equimolar G, T	(Keto)
	M is equimolar A, C	(aMino)
	R is equimolar A, G	(puRine)
	S is equimolar C, G	(Strong)
	W is equimolar A, T	(weak)
30	Y is equimolar C, T	(pYrimidine)

Table 6: Example of mixed nucleotides for wobbling

$e = 0.82 A + 0.06 C + 0.06 G + 0.06 T$

$q = 0.06 A + 0.82 C + 0.06 G + 0.06 T$

$$j = 0.06 A + 0.06 C + 0.82 G + 0.06 T$$

$$z = 0.06 A + 0.06 C + 0.06 G + 0.82 T$$

EXEMPLIFICATION

5 [00165] The present invention is further illustrated by the following examples which should not be construed as limiting in any way.

[00166] Prophetic Example 1: Libraries With Very Short HC CDR3s

[00167] Very short HC CDR3s have been described in the art. Kadirvelraj et al. (2006)
 10 *Proc. Natl. Acad. Sci. USA* 103:8149-54 have described a four amino-acid HC CDR3 sequence in an antibody that binds *Streptococcus* Type B III Ag (GBS-Ag) but not to *Streptococcus pneumoniae* capsular Ag. GBS-Ag is sialylated at regular intervals. *S. pneumoniae* capsular Ag (SPC-Ag) is very similar but lacks the sialic acid groups. Such a short HC CDR3 creates a wide groove into which a carbohydrate could bind, and such Abs are very, very rare in existing
 15 antibody libraries. Thus, current libraries do not afford a large variety of potential binders to carbohydrates.

[00168] Ab 1B1 is the murine mAb that binds GBS-Ag; Ab 1QFU is the mAb having a known 3D structure and the closest sequence; and INSN is an antibody of known 3D structure having a HC CDR3 of length 4. Examination of a 3-23 HC structure gives a distance from C α of
 20 R₉₄ (which ends FR3) to the C α of the W₁₀₄ (which begins FR4) of ~10 Å. The CDR3 of 1B1 (NWDY (SEQ ID NO:29)) shows that the AAs need not have only small side groups or be mostly of glycine. Three amino acids (AAs) can bridge 10 Å, although PPP might not work. Indeed, we have obtained a few Fabs with CDR3s as short as 3 AAs, but they are very rare.

[00169] Although short and very short HC CDR3s have been described, no one
 25 has suggested making an Ab library having many members (e.g., greater than about 50%, about 60%, about 70%, about 80%, about 90%, or about 95% of members) with short HC CDR3s (e.g., HC CDR3s of 3 to 5 amino acids). One approach to building an effective library is to first design amino-acid sequences that could arise from V-J or V-D-J coupling. For CDR3 length 3, 4, or 5, we start with the amino-acid sequences shown in Table 7. For example, Sequence V-
 30 3JH1 shows the C-terminal end of 3-23 FR3 (TAVYYCAK (SEQ ID NO:30)) followed by

JH1 which has been trimmed from the N-terminal end until three amino-acids before the Trp-Gly that starts FR4. V-3JH2 shows the end of FR3 followed by the trimmed JH2. The sequence following V-3JH6 are constructed by joining FR4 to a trimer taken from a human D segment followed by the FR4 region of a human JH segment. 3D3-3.3.2 would be a trimer from segment D3-3, third reading frame starting at the second amino acid. 5D5-12.2.3 is a pentamer from D5-12 in reading frame 2 starting at amino acid 3. Some of the germ-line D segments contain stop codons, yet they appear in natural antibodies when the stop codons are edited away: Here we assume that the most likely change from TAA and TAG codons is to Tyr (Y) and that TGA stops are most likely mutated to Trp (W). Table 20 shows the amino-acid sequences of the human D segments; the types of stop codons is indicated by the use of * for TAG, @ for TAA, and \$ for TGA. In Table 11 are 266 distinct trimers that can be constructed from human D segments. The TAA and TAG stops have been changed to Tyr shown as "y" (i.e., lowercase). These could also be changed to Ser, Cys, Phe, Gln, Lys, or Glu by single base changes. TAG could be changed by single base changes to Trp as well as Tyr, Gln, Lys, Glu, Ser, and Leu. Table 12 shows the 266 distinct tetramers that can be obtained by trimming human D segments. Table 13 shows the 215 pentamers that can be obtained from trimming human D segments. Table 14 shows the 155 hexamers that can be obtained by trimming human D segments. The libraries to be built have substantial diversity in HC CDR1 and HC CDR2. The sequence diversity of HC CDR3 may be less important than having a short, but acceptable sequence. The diversity of JH segments or fragments (e.g., 3 or more amino acids) of D segments provides sequences that could be built by the human immune system and so are less likely to be immunogenic.

[00170] In one embodiment, the trimers, tetramers, and pentamers that contain a Cys are eliminated.

[00171] In one embodiment, the trimers, tetramers, and pentamers that contain a Cys or the came from a D fragment containing a stop are eliminated.

[00172] The short libraries constructed using the trimers of Table 11, tetramers of Table 12, pentamers of Table 13 have substantial diversity: 266, 266, and 215 respectively. This is to be compared to the number of peptides of these lengths: 8000, 160000, and 3200000 respectively.

[00173] V-3D1-1.1.1-JH1 contains the final portion of FR3 followed by three amino acids from D1-1 (RF1), viz. GTT (SEQ ID NO:257). V-3D1-1.2-JH1 uses amino acids 2-4 of D1-1

(RF1) as the parental CDR3. V-3D3-3.3.3-JH2 shows the end of FR3 followed by amino acids 3-5 of D3-3 (RF 3). The invention comprises any amino-acid sequence comprising FR3::(three, four, or five stop-free AAs of a human D segment)::FR4 from a human JH. Fragments of D regions containing unpaired Cys residues are less preferred than those that are free of unpaired Cys residues. In V-5JH3, there is a Tyr shown as 'y' because JH3 has only 4 codons before the codons for Trp-Gly that define the beginning of FR4. V-5JH4 has a Ser shown as 's' for the same reason. If wobbling is used, the preferred level of purity is between 0.75 and 0.90. The invention comprises the sequences V-3JH1 through V-3JH6, V-4JH1 through V-4JH6, and V-5JH1 through V-5JH6, and libraries containing the same. The invention also comprises the sequences in which the CDR region is replaced by a 3, 4, or 5 amino-acid segment from a human D region, and libraries containing the same. The invention further comprises DNA in which the parental sequence has been mutated in the CDR3 region, and libraries containing the same. A preferred embodiment is one in which the average number of base changes per CDR3 is one, two, or three. The methods of mutagenesis include error-prone PCR, wobbling, and dobbing.

[00174] Alternatively, one could synthesize three fragments of DNA that correspond to the region from *Xba*I to *Bsr*EII and having residue 94 being K or R followed by 3, 4, or 5 NNK codons, followed by WG... of FR4. The allowed variation is $20^3 + 20^4 + 20^5 = 3,368,000$. After
25 amplification, these DNA molecules would be mixed in the ratio 1:10:100 (so that shorter sequences are relatively oversampled) and cloned into the phagemid encoding the kappa library with HC CDR1/2 diversity. A library of 1×10^9 would give significant diversity and will allow isolation of antibodies that bind to targets that have small to medium protrusions. For example, various carbohydrates, loops of proteins that are not well ordered (such as GPCRs) may benefit
30 from a groove in the antibody created by having a very short HC CDR3. We can also build a lambda library. The ratio of AA sequences is 1:20:400, and it may be important to sample the shorter sequences more densely. Getting a big, wide gulley in the Ab may require exactly one 3 AA CDR3, but with a 4 AA CDR3, one probably has more leeway and with 5 AAs, even more leeway. In this Example, we use the JH6 version of FR4 from the WG motif onward.

[00175] We can select from our current kappa library a collection of, for example, 25 kappa light chains that are a) germline in the framework regions, b) show suitable diversity in CDRs, and c) are of types that produce well and pair well with 3-23. These LCs will be made in *E. coli* from a vector that carries *Kan^R* and no phage packaging signal. We would then build our HC library in a phage vector that has no LC. HC and LC will be crossed by infecting the LC producing cells with the HC phage. HC phage that are selected can be combined with the LC of the cell that produces ELISA⁺ phage or the HCs can be cloned into pMID21 that have the whole LC diversity. Alternatively, the selected HC can be moved into pHCSK85 and used with ROLIC to combine with all the LCs of our collection. Lambda LCs could also be used. Thus, a library of 1×10^9 HC in phage can be expanded into a Fab library of 1.2×10^{11} ($1 \times 10^9 \times 117$). If we combined 1×10^7 CDR1-2s with 10^6 HC CDR3s, we could make a library of 5×10^7 in which each CDR3 is coupled with 50 CDR1-2s. A library of 5×10^7 HCs in phage could give results similar to an old-style library of 6×10^9 .

Alternatively, the current HC diversity can be cloned into DY3F87HC and the CDR3
 diversity described above is cloned into that diversity as XbaI - BstEII fragments. A library of,
 for example, 25 LC are cloned into pLCSK23 and used to create a cell line in TG1 *E. coli*.
 These cells are infected with the DY3F87HC phage which harbor the novel HC CDR3 (and
 40 CDR1-2) diversity. The phage obtained from this infection are selected for binding to a desired
 target. After two to four rounds of selection, the selected HCs are transferred to pHCSK22 and
 used to create a cell line which can be used with ROLIC to combine the selected HC with all the
 LCs in the ROLIC LC library. In this way, a library of 1. E 9 can be give Abs that normally
 would require construction of a library of 1. E 16 (assuming a LC diversity of 1. E 7).
 45

[00176] Prophetic Example 2: Libraries with Very Long HC CDR3s

[00177] Sidhu *et al.* (*J Mol Biol.* 2004 338:299-310. and US application 20050119455A1)
 report high-affinity Abs selected from a library in which only Y and S were allowed in the CDRs

which were limited in length to 20 amino acids. It may be possible to generate high affinity Abs from a library that has HC CDR3s with one or more of the following forms of diversity: a) several (but not all) sites allowing Y or S, b) including 4-6 NNK codons, c) introducing D segments (with or without diversification in the D), and/or d) using error-prone PCR. We have
5 already sampled the Ab space in which HC CDR3 is in the range ~8 to ~22 with a median length of 13. Thus, libraries in which HC CDR3 is either ~23 AAs or ~35 AAs are possible and may have advantages with certain types of targets. For example, GPCRs are integral membrane proteins with seven helical segments transversing the lipid bilayer of the cell that are thought to have multiple states. An antibody having a very long HC CDR3 could form a protuberance that
10 fits into the channel formed by the seven strands. Finding Abs that bind GPCRs has been difficult and intentionally building libraries in which all the members have very long HC CDR3s may ameliorate this problem. The lengths may be made somewhat variable, say 23, 24, or 25 in one library and 33, 34, or 35 in a second.

[00178] Below are a number of representative designs. The CDR3 have been broken up and diversity generated that lets the various parts have differing relationships depending on the
15 value of X. A full-length JH1 has been used, and in some designs diversity allowed diversity in the CDR3 part of JH1. Other JHs could be used. In the designs, the D segments are either rich in Y or have an S-rich disulfide loop. The amino-acid sequences of human D segments are shown in Table 3. The places where the D region has either S or Y or allowed other
20 combinations have in particular been varied. Table 4 shows the amino-acid sequences of human J regions.

[00179] Each of the libraries could be built in at least four ways: 1) DNA encoding a particular amino acid sequence is first synthesized and subjected to error-prone PCR, 2) the library can be synthesized by wobbling or with mixtures of nucleotides, 3) the library can be
25 built using dobbing, and 4) routes (2) or (3) could be followed by error-prone PCR. As an example of route (1), in Design 12, DNA encoding SEQ ID NO:908 could be synthesized, as shown in SEQ ID NO:911. This DNA could be subjected to error-prone PCR using the primers shown in SEQ ID NO:909 and SEQ ID NO:910. Because these primers cover the framework regions, the errors will occur only in the CDR3.

[00180] A library of HCs with CDR3 with length 23 of, for example, 2×10^9 members and a second library with HC CDR3s of length ~35 also having 2×10^9 members could be built. Alternatively, the DNA could be mixed to build one library of 4×10^9 .

Table 4: Human JH amino-acid sequences

5		H3

15	JH5	---NWFDPW QG TLVTVSS	(SEQ ID NO:68)
	JH6	YYYYYGMDVW QG TTVTVSS	(SEQ ID NO:3)

[00181] In each of the following designs, the amino-acid sequence begins with YYCA(K/R) which is the end of FR3. FR4 starts with WG and is shown bold.

Design 1

SEQ ID NO:898 comprises the end of FR3 joined to two residues (DY) of types often found in the filler sequence that the immune system places between V and D. These are followed by D2-2.2, preferred because it has a disulfide loop and is rich in Ser and Tyr residues. This is followed by YGYSY, which is rich in Tyr and Ser residues, which is followed by full-length JH1.

Amino-acid diversity = 1.28 E 8
 DNA diversity = 2.15 E 9
 15 Stop-free = 83%
 Gratuitous Cys-free = 83%
 Free of stop and Cys = 68%

Design 1(C23D222) has 94 being R or K, then 2 Xs, D2-2 in second reading frame with two Xs
 20 in the loop, followed by two Xs, and JH1. D2-2 2nd reading frame has a disulfide-closed loop
 into which diversity at two points has been introduced. This CDR3 is 23 long. Using primers
 that include DNA up to ...YYCA and from WGQG..., error-prone PCR on the CDR3 could be
 performed before amplifying out to *Xba*I and *Bst*EII for cloning into the library of kappa LC and
 HC CDR1/2. Thus, the AAs that are shown as fixed will be allowed to vary some. The AAs that
 25 are part of the PCR overlap region will be reinforced by the final non-error prone PCR. Error-
 prone PCR is not a necessary part of the design.

Selection against stop codons:

[00182] Because some of these libraries have NNK codons, they will have some TAG stop
 codons. We could remove the clones with TAG by cloning the amplified DNA into an *Xba*I-

*Bst*EII site between the signal sequence for a *bla* gene and the actual *bla* protein and express in Sup⁰ cells. Bla^R colonies do not contain TAG stops. Alternatively, we could clone the *Xba*I-*Bst*EII fragments ahead of a kanamycin-resistance gene and select for Kan^R. We would then move the *Xba*I-*Bst*EII cassette into the phage library.

- 5 [00183] Also, because wobbling allows some stop codons, we can improve the library by removing the clones with stops by cloning the amplified DNA into an *Xba*I-*Bst*EII site between the signal sequence for a *bla* gene and the actual *bla* protein and express in Sup⁰ cells. Bla^R colonies do not contain stops. Alternatively, we can clone the *Xba*I-*Bst*EII fragments ahead of a kanamycin-resistance gene and select for Kan^R. We can then move the *Xba*I-*Bst*EII cassette into
10 the phage library.

Table 11: Trimers that can be extracted from human D segments

In Tables 11-14, the use of a lower case letter in an amino acid sequence indicates that a stop codon was changed to the residue listed as the lower case letter. For example, in the amino acid sequence "yLE", a Tyr residue was introduced in place of a stop codon.

10 **Example 3: CDR3 of length 6-20.**

15 **[00184]** Insertion of D segments into synthetic HC CDR3s can lead to greater stability and lower immunogenicity. Libraries are designed at the amino-acid level by joining a VH to an optional filler of some length which is joined to a D segment an optional second filler and a JH. For libraries of length six or eight, a full-length JH may follow VH and a short filler. Table 77 shows the frequency of D segments in a sampling of 1419 Abs selected from FAB-310 or FAB-410 for binding to one target or another. In the sample, 1099 Abs had no detectable D segment (i.e., less than 70% match). Where D segments are used, the D segments D1-1.3, D1-26.3, D2-2.2, D2-8.2, D2-15.2, D2-21.2, D3-16.2, **D3-22.2**, **D3-3.2**, D3-9.1, D3-9.2, D3-10.2, D3-16.2, D4-4.2, D4-4.3, D4-11.2, D4-4.2, D4-17.2, D4-23.2, **D5-5.3**, **D5-12.3**, D5-18.3, D6-6.1, D6-6.2, **D6-13.1**, D6-13.2, **D6-19.1**, D6-19.2, and D7-27.1 are preferred.

20 **[00185]** Once the parental amino-acid sequence has been designed, it can be diversified in several ways: error-prone PCR, wobbling, and dobbling. Table 14 shows a number of hexamers that can be derived from human D regions. In one embodiment, the hexamers that contain cysteine residues are excluded. In one embodiment, the fragments of D regions that contain stops are excluded. In one embodiment, any TAG codon found in the D region is replaced by a codon picked from the set comprising TCG, TTG, TGG, CAG, AAG, TAT, and GAG. In one embodiment, any TAA codon found in the D region is replaced by a codon picked from the set comprising TCA, TTA, CAA, AAA, TAT, and GAA. In one embodiment, any TGA of the D region is replaced by a codon picked from the set comprising TGG, TCA, TTA, AGA, and GGA.

30 **[00186]** Table 21 shows exemplary parental amino-acid sequences for CDR3s from 6 to 20 amino acids. These parental sequences can be combined with diversity in HC CDR1 and CDR2 to form a library. The utility is likely to improve if the CDR3 regions are diversified by, for example, wobbling, dobbling, or error-prone PCR of the CDR3s. In Table 21, sequence 6a comprises the end of VH from 3-23 fused to whole JH1. Sequence 6b contains the end of 3-23 joined to a Y joined to D4-17 (RF 2) joined to the FR4 region of JH1. Sequence 6c contains the

35

end of 3-23 followed by D5-5 (RF 3) followed by the FR4 part of JH1. Sequence 6d contains the end of 3-23 joined to SY joined to the whole JH4. Table 21 shows the level of doping that would be appropriate for the wobbling of the CDR3; other levels could be used as well. Other D regions or fragments of D regions could be used. Other JH sequences could be used.

Table 21: Parental amino-acid sequences for HC CDR3s of 6-20 AAs.

```

40 Table 25: The DNA sequence of DY3F85LC containing a sample germline O12 kappa light chain. The antibody sequences shown are of the form of actual antibody, but have not been identified as binding to a particular antigen.

On each line, everything after an exclamation point (!) is commentary.

The DNA of DY3F85LC is SEQ ID NO:27

[00187] Example 4: Dobbling of CDRs

[00188] The following examples exemplify the use of dobbling in constructing synthetic
 libraries. The parental 3-23 heavy chain (HC) is diversified in CDR1, 2, and 3. This diversity is
 30 combined with a synthetically diversified A27 light chain (LC). The diversity will be as follows:

[00189] Example 4.1 HC CDR1

[00190] The following dobbling diversity allows 5,832 variants. See Table 50. At
 position 31, Ser is the germline (GL) amino-acid type. Hence we make Ser three times more
 35 likely than the other types. Since 18 types are allowed, Ser will be allowed 15% of the time and
 all the others are allowed at 5%. Thus, if there is no selection for the AA type at 31, we are more
 likely to isolate an Ab with Ser. Similarly, at 33 the GL AA type is Ala and we make Ala 3
 times as likely (15%) as all the others (5%). At 35 Ser is the GL AA type and we make it three
 times as likely as the others. At all three positions, we have excluded Cys and Met. We exclude
 40 Cys because we do not want gratuitous disulfides or exposed unpaired cysteines that could
 adversely affect the solubility and reactivity of the Ab. We exclude Met because exposed
 methionines side groups are subject to oxidation which can alter binding properties and shelf life.

We could make the germline amino-acid type 2, 3, 4, 5, 6, 8, or 10 times more likely than the other AA types.

Table 50: Diversity for CDR1 in 3-23

Position	Parental AA	Allowed
31	S (three-times more likely as the others)	ADEFGHKLNPQRSTVWY
33	A (3-X more likely)	ADEFGHKLNPQRSTVWY
35	S (3-X more likely)	ADEFGHKLNPQRSTVWY

5 [00191] Throughout this disclosure, the shown “Allowed” amino acids are the amino acids that can be used at a given position. For example, in Table 50, at position 31, allowed amino acids “ADEFGHKLNPQRSTVWY” are shown. This indicates that amino acids A, D, E, F, G, H, K, L, N, P, Q, R, S, T, V, W, and Y are all allowed at position 31.

[00192] Example 4.2: HC CDR2

10 [00193] In CDR2, we allow diversity at positions 50, 52, 52a, 56, and 58. At 50, 52, 56, and 58 we allow all amino-acid types except Cys and Met and we make the GL AA types more likely by three fold. We could make the GL AA type 2, 3, 4, 5, 6, 8, or 10 times more likely than the other AA types.

15 Table 51: HC CDR2: Diversity = 419,904

Position	Parental AA	Allowed
50	A (3-X more likely)	ADEFGHKLNPQRSTVWY
52	S (3-X more likely)	ADEFGHKLNPQRSTVWY
52a	G (3-X more likely)	GPSY
56	S (3-X more likely)	ADEFGHKLNPQRSTVWY
58	Y (3-X more likely)	ADEFGHKLNPQRSTVWY

[00194] Combined CDR1 and CDR2 diversity = 2.45 E 9

[00195] Example 4.3 HC CDR3, lengths 3, 4, 5

20 [00196] Very short CDR3 can be made by doobling. Table 7 shows several parental sequences for CDR3 length 3. At 94 many VH3s have Arg and we have allowed this change, but

Lys is made 3-X as likely. At 95, F is found at this position in JH1. We also allow Ser, Tyr, Asp, and Arg to allow small, large, plus charge, and minus charge. At 96, JH1 has Q. Since Q is very similar to Glu, we allow Glu as an acidic alternative plus Arg, Ser, Tyr, and Leu. At 97, His is the germline AA from JH1. We allow minus charge (D), plus charge (R), small polar (S),
 5 large hydrophobic (Y), and aliphatic (L). The parental sequence makes up 4.5% of the library, but this is combined with a large diversity in CDR1 and CDR2. The dobling allows 360 sequences in all. The least likely sequences occur at 1 in 1792. The most likely (parental) sequence occurs about 1 in 22.

10 Table 60: A doblled HC CDR3 of length 3 (V-3JH1 of Table 7)

Position	Parental amino acid (source)	Allowed
94	K (VH 3-23)	KR (3:1)
95	F (JH1)	FSYDR (3:1:1:1:1)
96	Q (JH1)	QERSYL (3:1:1:1:1:1)
97	H (JH1)	HDRSYL (3:1:1:1:1:1)
103	W (JH1)	W

[00197] Table 61 shows a doblled HC CDR3 of length 3. Here K94 is fixed as is W103. We have made the "parental" D segment amino acid five times as likely as the other allowed AA types.

15

Table 61: A doblled HC CDR3 of length 3 from a D fragment (V-3D1-1.1.2-JH1 of Table 7).

Position	Parental	Allowed
94	K (V 3-23)	K
95	T (D1-1.1.2)	TYRDL (5:1:1:1:1)
96	T (D1-1.1.2)	TYRDL (5:1:1:1:1)
97	G (D1-1.1.2)	GSYRDL (5:1:1:1:1:1)
103	W (JH1)	W

[00198] In this example (Table 62, using V-4JH2 from Table 8), 94 is fixed as Lys. At 95, JH2 has Tyr and we have allowed Ser, Asp, Arg, and Leu so that size, charge, and
 20 hydrophobicity can alter to suit the antigen. JH2 has Phe at 96 and we have allowed Ser, Tyr,

Asp, Arg, and Leu. At 97, JH2 has Asp and we have allowed Arg, Ser, Tyr, and Leu. At 98, JH2 has Leu and we have allowed Ser, Tyr, Asp, and Arg. This pattern allows 750 distinct sequences, of which the parental is the most likely (1 in 18). The least likely sequences occur at 1 in 4608 or 256 times less likely than the most likely.

5

Table 62: HC CDR3 length 4 from JH2 (V-4JH2 in Table 7)

Position	Parental AA (source)	Allowed
94	K (VH 3-23)	K
95	Y (JH2)	YSDRL (4:1:1:1:1)
96	F (JH2)	FSYDRL (4:1:1:1:1:1)
97	D (JH2)	DRSYL (4:1:1:1:1)
98	L (JH2)	LSYDR (4:1:1:1:1)
103	W (JH2)	W

[00199] In Table 63, there is a dobling of V-4D3-10.1a-JH2 from Table 8. At 94, we allow Lys and Arg with Lys (the parental) four times as likely as Arg. At 95, D3-10.1a (i.e., D3-10 in the first reading frame and starting a AA 1) has Leu; we allow SYDR as well with Leu 4-X as likely as each of the other AA types. At 96, D3-10.1a has Leu again and we allow the same menu. At 97, D3-10.1a has Trp and we allow Ser, Tyr, Asp, and Arg with Trp 4-X as likely. At 98, D3-10.1a has Phe and we allow Ser, Tyr, Asp, and Arg as well.

15 Table 63: HC CDR3 of length four from V-4D3-10.1a in Table 8

Position	Parental AA (source)	Allowed
94	K (VH 3-23)	KR (4:1)
95	L (D3-10.1a)	LSYDR (4:1:1:1:1)
96	L (D3-10.1a)	LSYDR (4:1:1:1:1)
97	W (D3-10.1a)	WSYDR (4:1:1:1:1)
98	F (D3-10.1a)	FSYDR (4:1:1:1:1)
103	W	W

[00200] Example 4.4: HC CDR3 length 10 to 20

[00201] HC CDR3

[00202] Two sublibraries, both with CDR3 of length 16:

Table 52: Library 1: Diversity = 5×10^{11} , the "parental" sequence occurs at 1 in 1.5×10^6 .

Position	"Parental" AA (source)	Allowed
94	K (3-X more likely) (3-23)	KR (3:1)
95	Y (3-X more likely) (D2-21(2))	YSRDL (3:1:1:1:1)
96	Y (3-X more likely) (D2-21(2))	YSRDL (3:1:1:1:1)
97	Y (3-X more likely) (D2-21(2))	YSRDL (3:1:1:1:1)
98	D (3-X more likely) (D2-21(2))	DYSRL (3:1:1:1:1)
99	S (3-X more likely) (D2-21(2))	SYRDL (3:1:1:1:1)
100	S (3-X more likely) (D2-21(2))	SYRDL (3:1:1:1:1)
101	G (3-X more likely) (D2-21(2))	GASYRDL (3:1:1:1:1:1)
102	Y (3-X more likely) (D2-21(2))	YSRDL (3:1:1:1:1)
102a	Y (3-X more likely) (D2-21(2))	YSRDL (3:1:1:1:1)
102b	Y (3-X more likely) (D2-21(2))	YSRDL (3:1:1:1:1)
102c	A (3-X more likely) (JH1)	ASYRD (3:1:1:1:1)
102d	E (3-X more likely) (JH1)	ERSYL (3:1:1:1:1)
102e	Y (3-X more likely) (JH1)	YSRDL (3:1:1:1:1)
102f	F (3-X more likely) (JH1)	FYSRD (3:1:1:1:1)
102g	Q (3-X more likely) (JH1)	QERSY (3:1:1:1:1)
102h	H (3-X more likely) (JH1)	HERSYL (3:1:1:1:1:1)
103	W (JH1, fixed)	W

5

Table 53: Library 2: CDR3 length 16; Diversity is 3.0×10^{10} and the parental sequence occurs once in 3.7×10^5 .

Position	"Parental" AA (source)	Allowed
94	K (3-X more likely) (3-23)	KR (3:1)
95	G (3-X more likely) (D2-2(2))	GSYDRL (3:1:1:1:1:1)
96	Y (3-X more likely) (D2-2(2))	YSDRL (3:1:1:1:1)
97	C (fixed) (D2-2(2))	C

98	S (3-X more likely) (D2-2(2))	SYRDL (3:1:1:1:1)
99	S (3-X more likely) (D2-2(2))	SYRDL (3:1:1:1:1)
100	T (3-X more likely) (D2-2(2))	TYRDL (3:1:1:1:1)
101	S (3-X more likely) (D2-2(2))	SYRDL (3:1:1:1:1)
102	C (fixed) (D2-2(2))	C
102a	Y (3-X more likely) (D2-2(2))	YSDRL (3:1:1:1:1)
102b	T (3-X more likely) (D2-2(2))	TYRDL (3:1:1:1:1)
102c	A (3-X more likely) (JH1)	ASYDRL (3:1:1:1:1:1)
102d	E (3-X more likely) (JH1)	ERSYL (3:1:1:1:1)
102e	Y (3-X more likely) (JH1)	YSDRL (3:1:1:1:1)

102g	Q (3-X more likely) (JH1)	QERSYL (3:1:1:1:1:1)
102h	H (3-X more likely) (JH1)	HDRSYL (3:1:1:1:1:1)
103	W (JH1)	W

[00203] Table 65 shows a dobbing variegation of SEQ ID NO:898. The total diversity allowed is 2.1×10^{13} . A synthesis that produces 1×10^8 , 3×10^8 , 5×10^8 , 1×10^9 , or 5×10^9 will sample the diversity adequately. The design of SEQ ID NO:898 was discussed above. In dobbing SEQ ID NO:898, is to allow the parental AA type at three-fold above other AA types at most positions. At positions where the parental is Tyr, then we use Tyr and Ser at equal amounts with Leu at one half that frequency. The Cys residues are fixed. Each parental AA type is allowed to go to one of Arg, Asp, Ser, Tyr, or Leu (Leu might be omitted if the parental is hydrophobic, such as Phe). The parental sequence will occur once in 1×10^8 members. The least likely sequences will occur once in 9.5×10^{16} . It is not important that the library actually contain the parental sequence, only that it contains many sequences that resemble the parent. Thus, a library that contains 1×10^7 , 5×10^7 , 1×10^8 , 3×10^8 , 1×10^9 , or 5×10^9 , when combined with diversity in HC CDR1, HC CDR2, LC CDR1, LC CDR2, and LC CDR3 will provide a library that will contain many valuable Abs.

Table 65: Dobbling of Design 1 with SEQ ID NO:898 as parent

Position	Parental (source)	Allowed

[00204] Example 4.5 Dobbling of yycakGSGYCSGGSCYSFDYwgqgtlvvss (SEQ ID NO:931)

[00205] Table 80 shows the dobbling of SEQ ID NO:931, an example of an HC CDR3 of length 15. Position 94 is part of FR3 and is held constant. Positions 95 and 96 have "parental" amino-acid types picked from the highly used set of (YGDRS) and are G95 and S96. The next ten positions are taken from D2-15.2 (a moderately highly used D segment containing a disulfide-closed loop). The final three positions are from the JH4 positions 100, 101, and 102 as shown in Table 3. At each position, we make the parental amino-acid type three times more likely than the other allowed types. The Cys residues are fixed. At 102e, Phe is three times more likely as are YGSRD (i.e., Phe is three times more likely as are any of amino acids Y, G, S, R, or D). The diversity allowed is 1.46×10^9 . The parental sequence is expected at 1 in 6.9×10^4 . Each of the singly substituted sequences is about 1/3 as likely; the doubly substituted ones are

1/9 as likely and so on. The sequences that are composed entirely of other AA types occur at only 1 in 1.1 E 11.

[00206] Each of the other sequences in Table 21 can be dobbled in the same way.

Table 80: Dobbling of yycakGSGYCSGGSCYSFDYwgqgtlvtvss (SEQ ID NO:931)

Position	Parental (source)	Allowed

5

[00207] **Example 5: Synthetic light chain diversity**

[00208] To make whole antibodies, we need to combine a library of heavy chains with a library of light chains (LC). In natural Abs, it is often observed that HC does most of the binding and many libraries have given little attention to the LC or have obtained LC diversity from human donors. To have enough diversity to give good binders to almost any target, we have designed a diversification program that exceeds what the human immune system usually provides. Nevertheless, the program is designed to yield fully functional LC that have the same kind of changes as seen in natural Abs, only a few more. Vkappa III A27 was picked as the LC.

10
15 [00209] From a library that comprises donated kappa and lambda LCs, a collection of 1266 Abs were typed. Among VKIIIs, A27 is most often seen (Table 66) and pairs well with HC 3-23.

[00210] The CDRs of A27 contain 12, 7, and 9 amino acids. Putting diversity at all of these positions might not work well: a) there might be many unstable or non-functional

members, and b) diversity at some positions might not help improve binding. We have reduced the number of variable positions from 28 to 16.

[00211] We have studied the 3D structure of 1QLR which has an A27 LC. The 1GLR structure is publicly available in the RCDB Protein Data Base. From this, the residues marked in Table 68 look useful to vary. The T56 is about 10 Å from a His in HC CDR3. Variation at 56 may be useful. G24 is only about 7 Å from an atom in HC CDR3. Germline is R24; thus, variation at 24 may be useful.

[00212] Table 69 shows a display cassette that we designed for use in pMID21. Thus, the restriction enzymes picked do not have other sites in pMID21. *SpeI* is in the *iii* signal sequence and allows the entire LC to be inserted or removed. *XmaI*, *PpuMI*, *EcoO109I*, and *BlpI* precede CDR1. *SacII* is in FR2, separating CDR1 from CDR2. Alternatively, an *AvrII* site could be inserted at the same position. *BspEI* and *XhoI* sites are in FR3 and a *KpnI* site is in FR4.

[00213] We gathered 155 A27 sequences and analyzed what happens in the CDRs. Table 70 shows the analysis. In Table 70, we show what is found in the Abs from our library and what we would put at each position.

L20	E						D	N				
L25	E	M					T	I				

VK3 differs from A27 by E1D, G9A, I58V, D60A, R77S.

A27 and L6 differ by G9A(FR1), Δ31a(in CDR1), G50D(CDR2), S53N(CDR2), G92S(CDR3), S93N(CDR3), S94W(CDR3)
VK3 from US 7,264,963.

[00214] CDR1

[00215] R24, A25, and S26 are too far from the combining site to help and were held constant. The side group of V29 is buried; this position was held constant as Val. At the other positions, we allowed Y or S and a charge flip-flop (RE or RD, depending on where the sample had more of E or D at the position in question) plus other types that were frequently seen. We used an Excel spread sheet to determine that this pattern of variegation would give the parental sequence at 0.8% if the "other" AAs were substituted at 5%, at 0.1% if the "other" AAs were substituted at 6.5%, and at 0.02% if "other" was at 9%. In the sample of 155, 17 have one AA deleted (including 1QLR); thus, we will arrange to have S30a deleted in ~8% of the members.

[00216] CDR2

[00217] From inspection of 1QLR, we see that CDR2 is somewhat remote from the combining site. There have even been suggestions that we keep the residues in this CDR constant. Studying the 3D structure suggests that variegation at G50, S53, and T56 could be useful. S53 is the most variable in the sample of 155, but this does not prove that these changes are useful. In 1QLR, G50 has been mutated to R50. The side group of T56 is pointed toward HC CDR3 and is about 11 Å from an atom in HC CDR3.

[00218] CDR3

[00219] Q89 and Q90 are buried and nature does not vary them often; these residues are not varied. Y91 is packed against HC CDR3 and changes here would alter the combining site and do occur. At G92, $\phi = -80$ and $\psi = -15$ so putting in a non-Gly is feasible; nature does it in 47/155 cases. S93 is very often varied or deleted. S94 is highly exposed and is highly varied. P95 is exposed and varied. L96 packs against HC CDR3: changes here will affect the binding site and do occur in nature. T97 is buried and has been held constant/ the amino acid is not varied.

[00220] The parental sequence appears at 0.000246 or 1 in 4.06 E3. The allowed diversity is about 2.1 E 12. With two 8% deletions, 84.6% of the members will be full length, 7.4% will

have short CDR1 and full-length CDR3, 7.4% will have full-length CDR1 and short CDR3, and 0.6% will have both deletions.

[00221] Other germlines were not in the sample.

There is one Ab with an insertion of 3 AAs.

Five have deletions of 4 AAs, 1 has a 3 AA deletion, 1 has a 2 AA deletion, and 17 have a one AA deletion.

[00222] The parental sequence appears at 5.32×10^{-5} or 1 in 1.88×10^4 .

[00223] Sequences with a single substitution have a probability between 1.1×10^{-5} and 7.5×10^{-6} .

[00224] Sequences that have none of the parental AAs occurs at 1 in 6.7×10^{16} .

[00225] The allowed diversity is about 2.35×10^{12} .

[00226] **Example 6: Wobbled DNA for HC CDR3 16d**

Table 400 shows a segment of DNA from an *XbaI* site in FR3 to a *BstEII* site in FR4. The HC CDR3 consists of SYSY::D2-2(2)::QH followed by the FR4 region of JH1. The QH is found in the germline of JH1. In V-D-J joining, immune cells often edit the ends of V, D, and J. Thus the construction corresponds to what is very possible in actual immunoglobulin gene construction and maturation. By wobbling the synthesis, we obtain a large collection of genes that resemble what would come from joining 3-23 to either a D region or to a little edited JH1 followed by some mutations. In library 16d, there are two cysteines that presumably form a disulfide, these are not wobbled.

Table 500 shows the expected distribution of amino-acid types at each position in the 16d library. The wobble doping was set at 73:9:9:9. The most likely sequence is the one shown in Table 21 and should be present at a frequency of 4.8 E-5. Only 55% of the sequences are stop free and 74% are free of ochre or opel. If the library is expressed in supE cells, this is the important number. It would be valuable to remove the sequences with stop codons as discussed elsewhere herein. One can see that those positions that start as S are predicted to have S 54% of the time and Y 5.4% while those that start as Y have Y 44% of the time and S 7.2%. At each position there are 7-9 AA types that appear at >1%. There are 14 variegated positions. The sequences that will be most effectively sampled number about $8^{14} = 4.3 \text{ E } 12$.

[00227] Example 7: Further examples of synthetic HC CDR3s

[00228] A collection of 22,063 Fabs with distinct CDR3 which had been selected from the FAB-310 or FAB-410 library and which were ELISA positive for at least one antigen were examined. The utilization of JH chains is shown in Table 1001; the FR4 part of each JH is shown **bold**. Table 1010 shows the utilization of amino acids in the HC CDR3s. Table 1020 shows the length distribution of CDR3. The median length is 11.5.

[00229] Table 1030 shows the utilization of D segments in the CDR3s. A D segment was identified is 70% of the amino acids matched; there were 5,654 cases (25.6%). The most used Ds were 3-3.2 (743, sequence: YYDFWSGYYT), 3-22.2 (617, sequence: YYYDSSGYYY), 6-19.1 (441, sequence: GYSSGWY), 6-13.1 (399, sequence: GYSSSWY), and 4-17.2 (392, sequence: DYGDY). Of the Ds containing paired Cys residues, 2-15.2 (sequence: GYCSGGSCYS) was the most used; there were 139 examples which is 0.6% of the collection.

[00230] When V or V::D is joined to J, there is often editing of the 3' end of V or V::D and the 5' end of J. Inspection of many CDR3-FR4 sequences shows that there is often a portion of JH making up part of CDR3. Often there are mutations in the CDR3 residues corresponding to JH residues 1-9. Herein the portion of CDR3 that is thought to derive from JH is called the "J stump". The JH used in a heavy chain is determined by comparing each of the residues of the six JH chains from position 6 to 20 to fusion of the last four amino acids of CDR3 to FR4. The JH that has the fewest mismatches is selected. The CDR3 sequence is examined for a J stump by working backward in the selected JH from position 9 toward the first position of the selected JH comparing to CDR3 until the search is terminated by a) the end of JH, b) the end of CDR3, or c) two consecutive mismatches. If one of the chains ends and the last compared position is a match, then it is included in J stump. If not, it is not. Table 1070 shows several examples. The CDR is written above, the JH is below, and the J stump is underlined. In 1070 A, we start at 9, V matches V, and we continue to position 6 with matches. The search stops at 4 because of the double mismatch. GMDV goes into the J stump pile and GL goes into the "Leadin" pile. In 1070 B, the search ends with the end of JH6. The underscored residues go into the J stump pile and EPIWG goes into the Leadin pile. In 1070 E, the search terminates because of the end of

JH4, but the final residue tested (D in the CDR vs Y in JH4) is a mismatch and so the J stump is FDS and DSGVVAAAD goes into the Leadin pile.

[00231] Table 1015 shows the amino-acid distribution of CDR3s that have no D segments from which the J stump has been removed. Note that the frequency of Tyr is much lower than when the whole CDR3s were compiled. This indicates that Tyr comes into CDR3s to a large extent through incorporation of D segments and J stumps. These Tyrs are not randomly inserted, but occur in a sequence that has been selected throughout mammalian evolution. It is a feature of the present invention that high levels (more than 20%) of Tyr should be inserted into libraries through the incorporation of Ds and J stumps that contain Tyr. At leadin or DJ filler positions, Tyr is allowed, but at no more than 20%.

[00232] Table 1082 shows the distribution of amino-acid usage in the J stumps of each JH. Since the most common JHs are JH3, JH4, and JH6, these are the preferred JHs on which to build libraries. Table 1082 shows that most examples of JH3 retain the tetrapeptide sequence AFDI in CDR3. With JH4, a majority retain DY and a large fraction retain the sequence FDY in CDR3. With JH6, a large majority retain the sequence DV, a majority retain the sequence MDV, and a substantial fraction retain the sequence GMDV. A non-negligible fraction retain the sequence YGMDV, YYGMDV, or YYYGMDV.

[00233] Included in libraries of the present invention are libraries such as 5.001 (Table 1097). Library 5.001 contains LC and HC CDR1-2 as described elsewhere in the present application. The library contains a HC VH (such as 3-23) followed by 6, 7, or 8 amino acids allowing [GSRDLY] in proportion shown in Table 1097. In the J stump, the parental amino acid is present at 3, 4, 5, 6, 7, 8, 10 times as likely as "other" amino-acid types. The "other" amino-acid types comprise Y, S, D, R, G. Thus at A6, we allow 7/12 A, plus 1/12 each of Y, S, D, R, and G. At F7, we allow 7/12 F plus 1/12 each of Y, S, D, R, and G. At D8, we allow 7/11 D plus 1/11 of Y, S, R, and G. At I9, we allow 7/12 I plus 1/12 Y, S, R, D, G. The parental amino acid could be 5, 6, 7, 8, 10 time more likely than the other amino-acid types.

[00234] Included in the libraries of the present invention is library 5.002 in Table 1097. This library comprises CDR3 of length 13, 14, and 15 and no D segment. There are 6, 7, or 8 leadin residues allowing G, S, R, D, L, or Y in the ratios 1:0.57:0.46:0.42:0.36:0.35 or reasonable approximation thereto. The CDR3 is completed with a portion of JH6: YYYGMDV. The DNA that encodes the parental sequence YYYGMDV is synthesized with the parental amino acid at 5, 6, 7, 8, or 10 times more likely than the others.

[00235] Included in the library of the present invention is library 5.003 in Table 1097. FR3 is followed by 4, 5, or 6 leadin residues allowing G, S, R, D, L, Y in the ratio 1.0:0.57:0.46:0.42:0.36:0.35. Next comes D segment 3-3.2; the DNA that encodes this region favors the parental amino acid by 5-fold and allows as other amino acids Y, G, D, R, S. There is no DJ filler and the final four amino acids come from the J stump of JH3. The DNA encoding the J stump are synthesized with the parental amino acid 5-fold more likely than the others: YSGRD.

[00236] Library 5.004 in Table 1097 is a part of the present invention. There are 2, 3, or 4 leadin residues allowing GSRDLY in the ratios shown. The DNA encoding the sequence GYSSGWY is synthesized so that the parental amino acid is 6-X as likely as the others, two DJ-filler residues are allowed with GSRDLY allowed in the ratios 1.0:0.57:0.46:0.42:0.36:0.35. The DNA to encode AFDI is synthesized with the parental amino acid 6-x as likely as the others.

[00237] Library 5.005 is part of the present invention. Library 5.005 comprises members with CDR3 lengths 11-14. After FR3, there are 0, 1, or 2 leadin residues allowing GSRDLY in the ratios shown followed by DNA that encodes the parental sequence GYSSGWY with variability that allows YGSRD such that the parental amino acid is 6-X as likely as the other

allowed types. Following the D region there is zero or one DJ filler residues allowing GSRDLY in the ratios shown. Finally is JH3 with variability in the J stump (sequence: YFDY) which allows YGSRD with the parental amino acid 6-X as likely as the other allowed types.

[00238] Library 5.006 in Table 1097 is part of the present invention. The CDR3 may be of length 19-25. There are zero to three leadin residues allowing GSRDLY in the ratios shown. Following the leadin is the D region 2-2.2. The DNA encoding 2-2.2 is synthesized so that the parental amino acid is 6-X as likely as the others (viz. YGSRD) except that the two Cys residues are fixed. Following 2-2.2 are zero to three DJ filler residues allowing GSRDLY in the ratios shown. The DNA that encodes the first nine residues of JH6 allows the parental amino acid plus YSGDR with the parental type being 6X more likely than the others.

EQUIVALENTS

[00242] A number of embodiments of the invention have been described. Nevertheless, it will be understood that various modifications may be made without departing from the spirit and scope of the invention. Accordingly, other embodiments are within the scope of the following claims.

CLAIMS:

1. A library of vectors or genetic packages, wherein the vectors or genetic packages comprise a first set of variegated DNA sequences that encode a first plurality of antibody heavy chain (HC) variable regions each comprising a heavy chain complementary
5 determining region 1 (HC CDR1), a heavy chain complementary determining region 2 (HC CDR2) and a heavy chain complementary determining region 3 (HC CDR3), wherein the HC CDR3 regions encoded by the first set of variegated DNA sequences are three amino acids in length and:
 - (i) the first residue of HC CDR3 varies among F, S, Y, D, and R in a 3:1:1:1:1
10 ratio; the second residue of HC CDR3 varies among Q, E, R, S, Y, and L in a 3:1:1:1:1:1 ratio; and the third residue of HC CDR3 varies among H, D, R, S, Y, and L in a 3:1:1:1:1:1 ratio; or
 - (ii) the first residue of HC CDR3 varies among T, Y, R, D, and L in a 5:1:1:1:1
ratio; the second residue of HC CDR3 varies among T, Y, R, D, and L in a 5:1:1:1:1 ratio; and
15 the third residue of HC CDR3 varies among G, S, Y, R, D, and L in a 5:1:1:1:1:1 ratio.
2. The library of claim 1, wherein a FR3 is located at the amino terminus of the CDR3, and the last residue of the FR3 varies between K and R in a 3:1 ratio.
3. The library of claim 1 or claim 2, wherein the vectors or genetic packages further
comprises a second set of variegated DNA sequences that encode a second plurality of
20 antibody heavy chain (HC) variable regions each comprising a HC CDR1, a HC CDR2, and a HC CDR3, wherein the HC CDR3 regions encoded by the second set of variegated DNA sequences are four amino acids in length and:
 - (i) the first residue of HC CDR3 varies among Y, S, D, R, and L in a 4:1:1:1:1
ratio; the second residue of HC CDR3 varies among F, S, Y, D, R, and L in a 4:1:1:1:1:1
25 ratio; the third residue of HC CDR3 varies among D, R, S, Y, and L in a 4:1:1:1:1 ratio; and the fourth residue of HC CDR3 varies among L, S, Y, D, and R in a 4:1:1:1:1 ratio; or

(ii) the first residue of HC CDR3 varies among L, S, Y, D, and R in a 4:1:1:1:1 ratio; the second residue of HC CDR3 varies among L, S, Y, D, and R in a 4:1:1:1:1 ratio; the third residue of HC CDR3 varies among W, S, Y, D, and R in a 4:1:1:1:1 ratio; and the fourth residue of HC CDR3 varies among F, S, Y, D, and R in a 4:1:1:1:1 ratio.

5 4. The library of claim 3, wherein a FR3 is located at the amino terminus of the CDR3 regions encoded by the second set of variegated DNA sequences, and the last residue of the FR3 varies between K and R in a 4:1 ratio.

5. The library of any one claims 1-4, wherein the vectors or genetic packages further comprises a third set of variegated DNA sequences that encode a third plurality of
10 antibody heavy chain (HC) variable regions each comprising a HC CDR1, a HC CDR2, and a HC CDR3, wherein the HC CDR3 regions encoded by the third set of variegated DNA sequences are sixteen amino acids in length and:

(i) the first residue of HC CDR3 varies among Y, S, R, D, and L in a 3:1:1:1:1 ratio; the second residue of HC CDR3 varies among Y, S, R, D, and L in a 3:1:1:1:1 ratio; the
15 third residue of HC CDR3 varies among Y, S, R, D, and L in a 3:1:1:1:1 ratio; the fourth residue of HC CDR3 varies among D, Y, S, R, and L in a 3:1:1:1:1 ratio; the fifth residue of HC CDR3 varies among S, Y, R, D, and L in a 3:1:1:1:1 ratio; the sixth residue of HC CDR3 varies among S, Y, R, D, and L in a 3:1:1:1:1 ratio; the seventh residue of HC CDR3 varies among G, A, S, Y, R, D, and L in a 3:1:1:1:1:1:1 ratio; the eighth residue of HC CDR3 varies
20 among Y, S, R, D, and L in a 3:1:1:1:1 ratio; the ninth residue of HC CDR3 varies among Y, S, R, D, and L in a 3:1:1:1:1 ratio; the tenth residue of HC CDR3 varies among Y, S, R, D, and L in a 3:1:1:1:1 ratio; the eleventh residue of HC CDR3 varies among A, S, Y, R, and D in a 3:1:1:1:1 ratio; the twelfth residue of HC CDR3 varies among E, R, S, Y, and L in a 3:1:1:1:1 ratio; the thirteenth residue of HC CDR3 varies among Y, S, R, D, and L in a
25 3:1:1:1:1 ratio; the fourteenth residue of HC CDR3 varies among F, Y, S, R, and D in a 3:1:1:1:1 ratio; the fifteenth residue of HC CDR3 varies among Q, E, R, S, and Y in a 3:1:1:1:1 ratio; and the sixteenth residue of HC CDR3 varies among H, E, R, S, Y, and L in a 3:1:1:1:1:1:1 ratio; or

(ii) the first residue of HC CDR3 varies among G, S, Y, D, R, and L in a 3:1:1:1:1:1 ratio; the second residue of HC CDR3 varies among Y, S, D, R, and L in a 3:1:1:1:1 ratio; the third residue of HC CDR3 is C; the fourth residue of HC CDR3 varies among S, Y, R, D, and L in a 3:1:1:1:1 ratio; the fifth residue of HC CDR3 varies among S, Y, R, D, and L in a 3:1:1:1:1 ratio; the sixth residue of HC CDR3 varies among T, Y, R, D, and L in a 3:1:1:1:1 ratio; the seventh residue of HC CDR3 varies among S, Y, R, D, and L in a 3:1:1:1:1 ratio; the eighth residue of HC CDR3 is C; the ninth residue of HC CDR3 varies among Y, S, D, R, and L in a 3:1:1:1:1 ratio; the tenth residue of HC CDR3 varies among T, Y, R, D, and L in a 3:1:1:1:1 ratio; the eleventh residue of HC CDR3 varies among A, S, Y, D, R, and L in a 3:1:1:1:1:1 ratio; the twelfth residue of HC CDR3 varies among E, R, S, Y, and L in a 3:1:1:1:1 ratio; the thirteenth residue of HC CDR3 varies among Y, S, D, R, and L in a 3:1:1:1:1 ratio; the fourteenth residue of HC CDR3 varies among F, Y, S, R, D, and L in a 3:1:1:1:1:1 ratio; the fifteenth residue of HC CDR3 varies among Q, E, R, S, Y, and L in a 3:1:1:1:1:1 ratio; and the sixteenth residue of HC CDR3 varies among H, D, R, S, Y, and L in a 3:1:1:1:1:1 ratio.

6. The library of claim 5, wherein a FR3 is located at the amino terminus of the CDR3 regions encoded by the third set of variegated DNA sequences, and the last residue of the FR3 varies between K and R in a 3:1 ratio.

7. The library of any one of claims 1-6, wherein the vectors or genetic packages further comprises a fourth set of variegated DNA sequences that encode A27 light chains (LCs) comprising a light chain complementary determining region 1 (LC CDR1), a light chain complementary determining region 2 (LC CDR2), and a light chain complementary determining region 3 (LC CDR3), wherein:

(i) the CDR1 regions of the LCs are diversified, wherein position 27 is about 55% Q, and about 9% each of E, R, Y, S, and L; position 28 is about 46% S and about 9% each of N, T, Y, E, R, and L; position 30 is about 55% S and about 9% each of D, N, R, T, and Y; position 30a is about 46% S and about 9% each of G, N, R, T, Y, and D, and about 8% with no amino acid; position 31 is about 44% S and about 8% each of D, F, G, N, R, T, and Y;

position 32 is about 44% Y and about 7% each of F, D, L, N, Q, R, S, and Y; and position 34 is about 70% A and about 15% each of S and Y;

(ii) the CDR2 regions of the LCs are diversified, wherein position 50 is about 55% G, and about 9% each of D, R, S, Y, and L; position 53 is about 52% S and about 8% each of N, T, S, Y, E, and R; and position 56 is about 64% T and about 9% each of E, R, S, and Y; and/or

(iii) the CDR3 regions of the LCs are diversified, wherein position 91 is about 64% Y, and about 9% each of F, E, R, and S; position 92 is about 52% G and about 8% each of A, D, R, S, T, and Y; position 93 is about 52% S and about 8% each of D, F, N, R, T, and Y; position 94 is about 55% S and about 9% each of W, E, R, Y, and S; position 95 is about 64% P and about 9% each of E, R, Y, and S, and about 8% with no amino acid; and position 96 is about 55% L and about 9% each of E, R, P, Y, and S.

8. The library of any one of claims 1-7, wherein the library is a library of vectors, which are phagemid vectors or yeast vectors

15 9. The library of any one of claims 1-7, wherein the library is a library of genetic packages, which are bacteriophages.
