20       Diabetes mellitus is a systemic disease characterized by metabolic disorders involving insulin, carbohydrates, fats and proteins, and disorders in the structure and function of blood vessels. The primary symptom of acute diabetes is hyperglycemia, often accompanied by glucosuria, the presence in urine of large amounts of glucose, and polyuria, the excretion of large volumes of urine. Additional symptoms arise in chronic diabetes, including degeneration of the walls of blood vessels. Although many different human organs are affected by these vascular changes, the eyes and kidneys appear to be  
25       the most susceptible. As such, long-standing diabetes mellitus, even when treated with insulin, is a leading cause of blindness.

30       There are three recognized types of diabetes mellitus. Type I diabetes or insulin dependent diabetes mellitus (IDDM) is typically of juvenile onset; ketosis develops early in life with much more severe symptoms and has a near-certain prospect of later vascular involvement. Control of Type I diabetes is difficult and requires exogenous insulin administration. Type II diabetes or non-insulin dependent diabetes mellitus (NIDDM) is ketosis-resistant, generally develops later in life, is milder and has a more gradual onset.

Gestational diabetes is related to type II diabetes and associated with an increased risk of later development of that disease. Type III diabetes is malnutrition-related diabetes.

NIDDM is a condition that poses a major threat to the health of the citizens of the western world. NIDDM accounts for over 85% of diabetes incidence worldwide and  
5 about 160 million people are suffering from NIDDM. The incidence is expected to increase considerably within the next decades, especially in developing countries. NIDDM is associated with morbidity and premature mortality resulting from serious complications, *e.g.* cardiovascular disease (G. C. Weir and J. L. Leahy, 1994, Pathogenesis of non-insulin dependent (Type II) diabetes mellitus, in *Joslin's Diabetes Mellitus* (Eds. C.  
10 R. Kahn and G. C. Weir), 13<sup>th</sup> Edition, 1994, Lea & Febiger, Malvern, PA, pp. 240-264). NIDDM is characterized by both fasting and post-prandial hyperglycemia resulting from abnormalities in insulin secretion and insulin action (G. C. Weir *et al.*, *vide supra*).

The hyperglycemia in patients suffering from NIDDM can usually be initially treated by dieting, but eventually most NIDDM patients have to take oral antidiabetic  
15 agents and/or insulin injections to normalize their blood glucose levels. The introduction of orally effective hypoglycemic agents was an important development in the treatment of hyperglycemia by lowering blood glucose levels. Currently, the most widely used oral antidiabetic agents are the sulfonylureas, which act by increasing the secretion of insulin from the pancreas (H. E. Lebovitz, Oral antidiabetic agents, in *Joslin's Diabetes Mellitus*  
20 (Eds. C. R. Kahn and G. C. Weir), 13<sup>th</sup> Edition, 1994, Lea & Febiger, Malvern, PA, pp. 508- 529), the biguanides (*e.g.*, metformin) which act on the liver and periphery by unknown mechanisms (C. J. Bailey, M. R. C. Path and R. C. Turner *N. Engl. J. Med.* 1996, 334, 574-579) and the thiazolidinediones (*e.g.*, rosiglitazone / Avandia®) which enhance the effects of insulin at peripheral target sites (G. L. Plosker and D. Faulds *Drugs*  
25 1999, 57, 409-438). These existing therapies which comprise a wide variety of biguanide, sulfonylurea and thiazolidinedione derivatives have been used clinically as hypoglycemic agents. However, all three classes of compound have side effects. The biguanides, for example metformin, are unspecific and in certain cases have been associated with lactic acidosis, and need to be given over a longer period of time, *i.e.* they are not suitable for  
30 acute administration (C. J. Bailey *et al.*, *vide supra*). The sulfonylureas, though having good hypoglycemic activity, require great care during use because they frequently cause serious hypoglycemia and are most effective over a period of circa ten years. The thiazolidinediones may cause weight gain following chronic administration (G. L. Plosker and D. Faulds, *vide supra*) and troglitazone has been associated with the  
35 occurrence of serious hepatic dysfunction.

Thus, there is a significant and rising need for antidiabetic drugs that have novel mechanisms of action, thereby avoiding side effects produced by known therapies. The hormone somatostatin (SST) is primarily produced in the intestinal tract and in the pancreas. In addition it acts as a neurotransmitter. The hormone is involved through its  
5 receptors in the regulation of several other hormones and in immunoregulation. In particular, SST suppresses the secretion of insulin by pancreatic  $\beta$  cells and the secretion of glucagon-like peptide 1 (GLP-1) by L cells. GLP-1 in turn is one of the most potent stimulators of insulin production and secretion and is a trophic factor for  $\beta$  cells.  $\beta$  and L cells express SST receptor subtype 5 (SSTR5) and agonizing this receptor suppresses  
10 insulin and GLP-1 secretion in humans and in animal models (*e.g.*, Y. Zambre, Z. Ling, M.-C. Chen, X. Hou, C.-W. Woon, M. Culler, J. E. Taylor, D. H. Coy, C. van Schravendijk, F. Schuit, D. G. Pipeleers and D. L. Eizirik *Biochem. Pharmacol.* 1999, 57, 1159-1164; S. P. Fagan, A. Azizzadeh, S. Moldovan, M. K. Ray, T. E. Adrian, X. Ding, D. H. Coy and F. C. Brunnicardi *Surgery* 1998, 124, 254-258; M. Norman, S. Moldovan, V. Seghers, X.-P. Wang, F. J. DeMayo and F. C. Brunnicardi *Ann. Surg.* 2002, 235, 767-774;  
15 T.A. Tirone, M. A. Norman, S. Moldovan, F. J. DeMayo, X.-P. Wang and F. C. Brunnicardi *Pancreas* 2003, 26, e67-73; M. Z. Strowski, M. Köhler, H. Y. Chen, M. E. Trumbauer, Z. Li, D. Szalkowski, S. Gopal-Truter, J. K. Fisher, J. M. Schaeffer, A. D. Blake, B. B. Zhang and H. A. Wilkinson *Mol. Endocrinol.* 2003, 17, 93-106).

20 Consequently, antagonizing the effect of SST would lead to higher plasma insulin concentrations. In patients suffering from impaired glucose tolerance and NIDDM, a higher plasma insulin concentration would moderate the dangerous hyperglycemia and accordingly reduce the risk of tissue damage. If such SSTR5 antagonists are sufficiently selective over the other four SST receptors, little influence is expected on secretion of  
25 other hormones. Particularly, selectivity over SST receptor subtype 2 avoids influences on glucagon secretion (K. Cejvan, D. H. Coy and S. Efendic *Diabetes* 2003, 52, 1176-1181; M. Z. Strowski, R. M. Parmar, A. D. Blake and J. M. Schaeffer *Endocrinology* 2000, 141, 111-117). Advantageous over established therapies is the dual mechanism of action to increase insulin secretion: directly on pancreatic  $\beta$  cells and indirectly through GLP-1  
30 release from L cells. Additionally, SSTR5 knockout mice demonstrated higher insulin sensitivity than littermates (M. Z. Strowski, M. Köhler *et al.*, *vide supra*). Therefore, SSTR5 antagonists could have the potential to beneficially influence insulin resistance in patients with NIDDM. In summary, SSTR5 antagonists are expected to beneficially influence NIDDM, the underlying impaired fasting glucose and impaired glucose  
35 tolerance, as well as complications of long-standing, insufficiently controlled diabetes mellitus.

GLP-1 is known as an endogenous regulator of gastrointestinal motility and of food intake reducing appetite as shown in laboratory animals, healthy volunteers and patients with NIDDM (E. Näslund, B. Barkeling, N. King, M. Gutniak, J. E. Blundell, J. J. Holst, S. Rössner and P. M. Hellström *Int. J. Obes.* 1999, 23, 304-311; J.-P. Gutzwiller, B. Göke, J. Drewe, P. Hildebrand, S. Ketterer, D. Handschin, R. Winterhalder, D. Conen and C. Beglinger *Gut* 1999, 44, 81-88; J.-P. Gutzwiller, J. Drewe, B. Göke, H. Schmidt, B. Rohrer, J. Lareida and C. Beglinger *Am. J. Physiol.* 1999, 276, R1541-1544; M. D. Turton, D. O'Shea, I. Gunn, S. A. Beak, C. M. Edwards, K. Meeran, S. J. Choi, G. M. Taylor, M. M. Heath, P. D. Lambert, J. P. Wilding, D. M. Smith, M. A. Ghatei, J. Herbert and S. R. Bloom *Nature* 1996, 379, 69-72; A. Flint, A. Raben, A. Astrup and J. J. Holst *J. Clin. Invest.* 1998, 101, 515-520; M. B. Toft-Nielsen, S. Madsbad and J. J. Holst *Diabetes Care* 1999, 22, 1137-1143; P. K. Cheikani, A. C. Haver and R. D. Reidelberger *Am. J. Physiol.* 2005, 288, R1695-R1706; T. Miki, K. Minami, H. Shinozaki, K. Matsumura, A. Saraya, H. Ikeda, Y. Yamada, J. J. Holst and S. Seino *Diabetes* 2005, 54, 1056-1063); thus, elevated GLP-1 will also counteract obesity, a typical condition associated with and leading to NIDDM.

GLP-1 is co-secreted with GLP-2 that is, consequently, also regulated by SST through SSTR5 (L. Hansen, B. Hartmann, T. Bisgaard, H. Mineo, P. N. Jørgensen and J. J. Holst *Am. J. Phys.* 2000, 278, E1010-1018). GLP-2 is enterotrophic and beneficial in patients with malabsorption of certain origins, such as short bowel syndrome (D. G. Burrin, B. Stoll and X. Guan *Domest. Anim. Endocrinol.* 2003, 24, 103-122; K. V. Haderslev, P. B. Jeppesen, B. Hartmann, J. Thulesen, H. A. Sorensen, J. Graff, B. S. Hansen, F. Tofteng, S. S. Poulsen, J. L. Madsen, J. J. Holst, M. Staun and P. B. Mortensen *Scand. J. Gastroenterol.* 2002, 37, 392-398; P. B. Jeppesen *J. Nutr.* 2003, 133, 3721-3724).

Moreover, there is increasing evidence for a role of SST on immune cells and expression of SSTR5 on activated T lymphocytes (T. Talme, J. Ivanoff, M. Hägglund, R. J. J. van Neerven, A. Ivanoff and K. G. Sundqvist *Clin. Exp. Immunol.* 2001, 125, 71-79; D. Ferone, P. M. van Hagen, C. Semino, V. A. Dalm, A. Barreca, A. Colao, S. W. J. Lamberts, F. Minuto and L. J. Hofland *Dig. Liver Dis.* 2004, 36, S68-77; C. E. Ghamrawy, C. Rabourdin-Combe and S. Krantic *Peptides* 1999, 20, 305-311). Consequently, SSTR5 antagonists could also prove valuable in treating diseases characterized by a disturbed immune system, such as inflammatory bowel disease.

It is therefore an object of the present invention to provide selective, directly acting SSTR5 antagonists. Such antagonists are useful as therapeutically active substances,

particularly in the treatment and/or prevention of diseases which are associated with the modulation of SST receptors subtype 5.

“Isomers” are compounds that have identical molecular formulae but that differ in the nature or the sequence of bonding of their atoms or in the arrangement of their atoms in space. Isomers that differ in the arrangement of their atoms in space are termed “stereoisomers”. Stereoisomers that are not mirror images of one another are termed

20 “diastereoisomers”, and stereoisomers that are non-superimposable mirror images are termed “enantiomers”, or sometimes optical isomers. A carbon atom bonded to four nonidentical substituents is termed a “chiral center”.

quinazolin-2-yl)-amine,  
and pharmaceutically acceptable salts thereof.

- 15 Furthermore, the pharmaceutically acceptable salts of the compounds of formula I  
individually constitute preferred embodiments of the present invention.

- Compounds of formula I can have one or more asymmetric carbon atoms and can  
exist in the form of optically pure enantiomers, mixtures of enantiomers such as, for  
example, racemates, optically pure diastereoisomers, mixtures of diastereoisomers,  
20 diastereoisomeric racemates or mixtures of diastereoisomeric racemates. The optically  
active forms can be obtained for example by resolution of the racemates, by asymmetric  
synthesis or asymmetric chromatography (chromatography with a chiral adsorbent or  
eluant). The invention embraces all of these forms.

- It will be appreciated, that the compounds of general formula I in this invention  
25 may be derivatised at functional groups to provide derivatives which are capable of  
conversion back to the parent compound in vivo. Physiologically acceptable and  
metabolically labile derivatives, which are capable of producing the parent compounds of  
general formula I in vivo are also within the scope of this invention.

A further aspect of the present invention is the process for the manufacture of compounds of formula I as defined above, which process comprises

a) reacting a compound of the general formula

5 wherein G is as defined herein before and X is a leaving group, with a compound of the formula

wherein A and R<sup>1</sup> to R<sup>5</sup> are as defined herein before, to obtain a compound of the formula

10

and, if desired, converting the compound of formula I into a pharmaceutically acceptable salt; or, alternatively,

b) reacting a compound of the general formula

15 wherein G is as defined herein before, with an aldehyde of the formula

- 39 -

wherein A and R<sup>1</sup> to R<sup>5</sup> are as defined herein before,  
by employing a reducing agent to obtain a compound of the formula

- 5 and, if desired, converting the compound of formula I into a pharmaceutically acceptable salt.

The invention further relates to compounds of formula I as defined above, when manufactured according to a process as defined above.

- 10 Suitable reducing agents are preferably selected from the group consisting of pyridine-BH<sub>3</sub> complex, NaBH(OAc)<sub>3</sub> and NaCNBH<sub>3</sub>. The reaction can be carried out under acidic conditions by using an acid such as acetic acid or formic acid or an Lewis acid (*e.g.*, Ti(*i*PrO)<sub>4</sub>, ZnCl<sub>2</sub>) or under basic conditions (no additive) in a suitable solvent such as dichloromethane, dichloroethane or ethanol (or mixtures thereof) at ambient or elevated temperatures using conventional heating or heating by microwave irradiation.

- 15 As described above, the compounds of formula I of the present invention can be used as medicaments for the treatment and/or prevention of diseases which are associated with the modulation of SST receptors subtype 5.

- 20 “Diseases which are associated with the modulation of SST receptors subtype 5” are such diseases as diabetes mellitus, particularly type II diabetes mellitus, impaired fasting glucose, impaired glucose tolerance, micro- and macrovascular diabetic complications, posttransplantation diabetes mellitus in patients having type I diabetes mellitus, gestational diabetes, obesity, inflammatory bowel diseases such as Crohn’s disease or ulcerative colitis, malabsorption, autoimmune diseases such as rheumatoid arthritis,

osteoarthritis, psoriasis and other skin disorder, and immunodeficiencies. Microvascular diabetic complications include diabetic nephropathy and diabetic retinopathy, whereas macrovascular diabetes-associated complications lead to an increased risk for myocardial infarction, stroke and limb amputations.

- 5           The use as medicament for the treatment and/or prevention of diabetes mellitus, particularly type II diabetes mellitus, impaired fasting glucose or impaired glucose tolerance is preferred.

The invention therefore also relates to pharmaceutical compositions comprising a compound as defined above and a pharmaceutically acceptable carrier and/or adjuvant.

- 10           Further, the invention relates to compounds as defined above for use as therapeutically active substances, particularly as therapeutic active substances for the treatment and/or prevention of diseases which are associated with the modulation of SST receptors subtype 5.

- 15           In another embodiment, the invention relates to a method for the treatment and/or prevention of diseases which are associated with the modulation of SST receptors subtype 5, which method comprises administering a compound of formula I to a human or animal. The method for the treatment and/or prevention of diabetes mellitus, particularly type II diabetes mellitus, impaired fasting glucose or impaired glucose tolerance, is most preferred.

- 20           The invention further relates to the use of compounds as defined above for the treatment and/or prevention of diseases which are associated with the modulation of SST receptors subtype 5.

- 25           In addition, the invention relates to the use of compounds as defined above for the preparation of medicaments for the treatment and/or prevention of diseases which are associated with the modulation of SST receptors subtype 5. Preferred examples of such diseases are diabetes mellitus, particularly type II diabetes mellitus, impaired fasting glucose or impaired glucose tolerance.

- 30           The compounds of formula I can be manufactured by the methods given below, by the methods given in the examples or by analogous methods. Appropriate reaction conditions for the individual reaction steps are standard reactions and are known to a person skilled in the art. Starting materials are either commercially available or can be prepared by methods analogous to the methods given below, by methods described in references cited in the text or in the examples, or by methods known in the art.

The synthesis of compounds of the general formula I, particularly compounds according to formula Ic can be accomplished according to Scheme 1.

Scheme 1

- 5 Reductive *N*-alkylation of suitably protected piperidines (for protecting groups see *Protective Groups in Organic Synthesis*, T. W. Greene and P. G. M. Wuts, 3<sup>rd</sup> Edition, 1999, Wiley-Interscience) of formula 1 with aldehydes 2 in the presence of a reducing agent such as pyridine-BH<sub>3</sub> complex, NaBH(OAc)<sub>3</sub> or NaCNBH<sub>3</sub> under acidic conditions (*e.g.*, acetic acid, formic acid), by using a Lewis acid (*e.g.*, Ti(*i*PrO)<sub>4</sub>, ZnCl<sub>2</sub>) or under
- 10 buffered conditions, *e.g.*, in the presence of acetic acid and a tertiary amine like *N*-ethyl diisopropylamine or triethylamine in a suitable solvent such as dichloromethane, dichloroethane, ethanol or isopropanol (or mixtures thereof) at ambient or elevated temperatures using conventional heating or heating by microwave irradiation provide piperidines of general formula 3 (Scheme 1, step a). The piperidines of formula 1 may
- 15 thereby used either as a salt, *e.g.*, hydrochloride or hydrobromide salt, or as the corresponding free amine. The alkoxycarbonyl protecting group present in compounds 3 can be removed, using *e.g.*, 48% aqueous hydrogen bromide or 37% aqueous hydrochloric acid as reagent preferably at elevated temperatures to remove an ethyl

carbamate or using trifluoroacetic acid or hydrochloric acid in a solvent like dichloromethane, dioxane or THF preferable at room temperature to remove a *tert*-butyloxycarbonyl (BOC)-protective group (see *Protective Groups in Organic Synthesis*, T. W. Greene and P. G. M. Wuts, 3<sup>rd</sup> Edition, 1999, Wiley-Interscience), yielding 4-amino-  
5 piperidines of formula 4 (Scheme 1, step b).

Target compounds of formula I can be synthesized by nucleophilic replacement reaction of 4-amino-piperidines of formula 4 and a variety of pyrimidines, quinazolines, pteridines or triazines of general structure 5 at room or elevated temperatures (Scheme 1, step c), whereby X is a suitable leaving group such as fluorine, chlorine, bromine or  
10 methyl sulfone. Thereby heating can be achieved conventionally or by microwave irradiation using a suitable microwave irradiation apparatus. Furthermore the reaction can be conducted in the presence of or without solvent (typically an aprotic polar solvent such as DMF (*N,N*-dimethylformamide), DMAc (dimethylacetamide), NMP (*N*-methylpyrrolidon), ethylene glycol, acetonitrile or THF) and in the presence of or  
15 without a tertiary amine base such as triethylamine, *N*-ethyl diisopropylamine or pyridine and in the presence with or without copper(I) bromide or copper(I) iodide. In order to enhance the rate of conversion heating might be applied, whereby conventional heating or microwave assisted heating might be employed. The starting materials and some of the intermediates of general structure 5 (*e.g.*, 2-chloro-pyrimidines, 2-chloro-  
20 quinazolines, 2-chloro-pteridines or 2-chloro-triazines) are known compounds and are commercially available or can be prepared by numerous methods using conventional reaction procedures generally known in the art. The 4-amino-piperidines of formula 4 may thereby used either as a salt, *e.g.*, hydrochloride or hydrobromide salt, or as the corresponding free amine. Alternatively the nucleophilic displacement reaction can be  
25 conducted under basic conditions by using K<sub>2</sub>CO<sub>3</sub>, KOH, NaOCH<sub>3</sub>, KO<sup>*tert*</sup>-Bu or in particular by using NaH. If the coupling reaction is conducted with 2,4-dihalo-pyrimidines or 2,4-dihalo-quinazolines, preferentially with 2,4-dichloro-pyrimidines, regioisomeric coupling products might be obtained, which can be separated by conventional chromatographic methods. In cases where nucleophilic substitution leads  
30 to regioisomeric products the regiochemistry of target structures I was unambiguously established by means of nuclear magnetic resonance spectroscopy employing 1D-NOE difference, 2D-NOESY and/or <sup>13</sup>C/<sup>1</sup>HMBC experiments. In some cases <sup>1</sup>H NMR spectra revealed the presence of tautomeric structures at room temperature (rt).

Alternatively target structures I can be achieved using Pd(0)-catalyzed amination  
35 reactions of 2-halo pyrimidines of formula 5 with 4-amino-piperidines 4 (*e.g.*, Buchwald-Hartwig coupling; see (a) J. P. Wolfe, S. Wagaw and S. L. Buchwald *J. Am. Chem. Soc.*

- 1996, 118, 7215-7216; (b) J. P. Wolfe and S. L. Buchwald *Tetrahedron Lett.* 1997, 38, 6359-6362; (c) J. P. Wolfe, S. Wagaw, J.-F. Marcoux and S. L. Buchwald *Acc. Chem. Res.* 1998, 31, 805-818; (d) B. H. Yang and S. L. Buchwald *J. Organomet. Chem.* 1999, 576, 125-146; (e) J. F. Hartwig *Angew. Chem. Int. Ed.* 1998, 37, 2046-2067). Thereby halo-
- 5 substituted heterocycles 5 are reacted with amines 4 under an inert atmosphere such as argon or nitrogen in the presence of a palladium catalyst such as tris(dibenzylideneacetone)dipalladium(0) ( $\text{Pd}_2(\text{dba})_3$ ) or palladium(II) acetate ( $\text{Pd}(\text{COOCH}_3)_2$ ), a phosphine ligand like triphenylphosphine, *rac*-2,2'-bis(diphenylphosphino)-1,1'-binaphthalene (*rac*-BINAP) or (R)-(-)-1-[(S)-2-
- 10 (dicyclohexylphosphino)ferrocenyl]ethyl-di-*tert*-butylphosphine (Josiphos; see Q. Shen, S. Shekhar, J. P. Stambuli and J. F. Hartwig, *Angew. Chem. Int. Ed.* 2005, 44, 1371-1375) and a base such as  $\text{Cs}_2\text{CO}_3$  or  $\text{KO}^{\text{tert}}\text{-Bu}$  in a solvent like toluene, ethanol or water or mixtures thereof (Scheme 1, step c). Said C-N formation reaction may be conducted at room temperature or elevated temperatures, whereby heating might be achieved
- 15 conventionally or by microwave irradiation (see also Palladium(0) Complexes in Organic Chemistry, in *Organometallics in Synthesis* (Ed. M. Schlosser), Chapter 4, 2<sup>nd</sup> Edition, 2002, John Wiley & Sons, Ltd, Chichester, UK).

Target structures of formula I can also be accomplished employing an inverted reaction sequence, namely by first coupling halo-substituted heterocycles 5 with alkyloxycarbonyl protected amine 6 (Scheme 2, step a) yielding intermediate 7. Intermediates 7 can be further processed as such, or optionally, any of the substituents  $R^{10}$ ,  $R^{11}$  or  $R^{12}$  can be exchanged, modified, extended or removed by methods well known in the art and described in more detail in the examples. The protection group(s) of piperidines 7 are then removed yielding the secondary amines 8 (Scheme 2, step b), which undergo reductive *N*-alkylation to target structures I (Scheme 2, step c). In contrast to the strategy outlined in Scheme 1 where the point of diversification is the heteroaryl moiety this synthetic route is of particular interest if the variation of the benzyl moiety is aimed for in a rapid and parallel fashion.

Scheme 2

Target compounds of formula I might also be synthesized by direct alkylation of piperidines 8 with suitable halides, mesylates, tosylates or alcohols containing any other suitable leaving group of structure 9 in a solvents such as *N,N*-dimethylformamide,

dichloromethane, dichloroethane or acetone at ambient or elevated temperatures using conventional heating or heating by microwave irradiation with the addition of a suitable tertiary amine base (*e.g.*, triethylamine, *N*-ethyl diisopropylamine) or an inorganic base (*e.g.*, Cs<sub>2</sub>CO<sub>3</sub>, K<sub>2</sub>CO<sub>3</sub>; Scheme 3, step a) or by analogous alkylation reactions.

- 5 Alternatively target structures of formula I might be accessible by *Mitsunobu* reaction applying alcohols 10 activated by a mixture of triphenylphosphine and diethyl- or di-*tert*-butyl-azadicarboxylate (Scheme 3, step b).

Scheme 3

## 10 Synthesis of pyrimidine and quinazoline intermediates

- The starting materials of general formula IIa are either commercially available, known in the literature or can be obtained on application of classical methods of pyrimidine synthesis and subsequent functional group conversion such as by condensation of  $\beta$ -keto carboxylic acids 11 (malonic esters) with urea (12) as illustrated in step a of Scheme 4 (*e.g.*, see Y.-Z. Kim, J.-C. Lim, J.-H. Yeo, C.-S. Bang, W.-S. Kim, S.-S. Kim, Y.-M. Woo, D.-H. Yang, H. Oh and K. Nahm *J. Med. Chem.* 1994, 37, 3828-3833). Halogenation of the pyrimidine intermediates 13 to provide compounds of

general formula IIa can be accomplished in refluxing  $\text{POCl}_3$  or  $\text{PCl}_3/\text{PCl}_5$  (Scheme 4, step b; see also H. Krauch and W. Kunz, *Reaktionen der organischen Chemie*, 6., neubearbeitete Auflage, 1997, Hüthig GmbH, Heidelberg, Deutschland). The corresponding bromo derivatives of IIa are accessible when  $\text{POBr}_3$  is used instead of  $\text{POCl}_3$  as the halogenation agent. Furthermore, the halogenation step can be conducted in the presence or absence of catalytic amounts of *N,N*-dimethylaniline. All of these reactions are standard operations and can be carried out under conditions which are usual for such reactions and which are familiar to a person skilled in the art.

Scheme 4

10

Alternatively, the preparation of target structures IIa can be achieved by condensation of  $\beta$ -keto carboxylic acids 11 (malonic esters) with guanidine (14) yielding 2-amino pyrimidines 15 (Traube synthesis; see A. R. Katritzky and T. I. Yousaf *Canad. J. Chem.* 1986, 64, 2087-2093; Scheme 5, step a). The 4-hydroxy group in pyrimidines 15 can be converted to chloride employing standard halogenation conditions such as refluxing  $\text{POCl}_3$  or  $\text{PCl}_3/\text{PCl}_5$  (Scheme 5, step b). The 2-amino group in pyrimidines 16 can then be transformed to chloride employing standard Sandmeyer reaction conditions such as diazotization with sodium nitrite in the presence of hydrochloric acid at lower temperatures preferentially between  $-10^\circ\text{C}$  and  $10^\circ\text{C}$  yielding 2,4-dichloro-pyrimidines (Scheme 5, step c). Alternatively, the Sandmeyer reaction can be conducted directly on pyrimidine 15 providing access to 2-chloro-4-hydroxy pyrimidines.

15

20

Scheme 5

Alternatively, 2-amino pyrimidines 17 can be obtained by ring closure reaction of enamino ketones 18 (H. H. Wasserman and J. L. Ives *J. Am. Chem. Soc.* 1976, 98, 7868-7869) with guanidine (15) in the presence of a base such as sodium methylate in a solvent like ethanol at room or elevated temperatures (Scheme 6, step a). Conversion of the 4-hydroxy group in pyrimidines 17 to chloride can be achieved using standard halogenation conditions such as refluxing POCl<sub>3</sub> or PCl<sub>3</sub>/PCl<sub>5</sub> (Scheme 6, step b).

Scheme 6

In case of R<sup>4</sup> is 2-thienyl regioselective lithiation at the  $\alpha$  position to the nitrogen with (2-thienyl)lithium of pyrimidines 19 in diethyl ether at -30 °C followed by oxidation with 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ) leads to the desired product IIa (Scheme 7, step a; D. B. Harden, M. J. Mokrosz and L. Strekowski *J. Org. Chem.* 1988, 53, 4137-4140). The method is also amenable to R<sup>4</sup> = methyl, *n*-butyl, phenyl, 3-thienyl and there like.

Further syntheses of pyrimidines of formula IIa are described in the examples.

- The starting materials of general formula IIb are either commercially available, known in the literature or can be obtained on application of classical methods of 10 quinazoline synthesis. A classical route for the synthesis of quinazolines IIb is outlined in Scheme 8. Condensation of anthranilic acids 20 and sodium cyanate in water and glacial acetic acid furnishes quinazoline-2,4-diols 21 (step a), which upon subsequent functional group conversion, *e.g.*, treatment at elevated temperatures with phosphorus oxychloride in chloroform or neat and in the presence or absence of *N,N*-dimethylaniline as a 15 catalyst, provide 2,4-dichloro-quinazolines IIb (step b). The two halogenes in IIb exhibit different chemical reactivity, with the chloride at the C2 position being inherently less reactive. This allows the sequential replacement of first the C4 and second the C2 chloride atom, *e.g.*, by nucleophilic substitution reactions with amines or aliphatic or aromatic alcohols or by Pd(0)-catalyzed Suzuki, Buchwald-Hartwig or Stille-type 20 coupling reactions, providing access to a large number of differently substituted intermediates of general structure IIb. Likewise this synthetic strategy can be applied to 2,4-dichloro-pyrimidines, where a similar difference in reactivity of the two halogen atoms is also observed. The regiochemistry of target structures IIb can unambiguously be established by means of nuclear magnetic resonance spectroscopy employing 1D-NOE 25 difference, 2D-NOESY and/or <sup>13</sup>C/<sup>1</sup>HMBC experiments.

Scheme 8

Most of the synthetic routes outlined in Scheme 4 to Scheme 8 are amenable to both solution and solid-phase synthesis (see J. T. Bork, J. W. Lee and Y.-T. Chang *QSAR* 5 *Comb. Sci.* 2004, 23, 245-260).

Further syntheses of quinazolines of formula IIb are described in the examples.

#### Synthesis of aldehyde intermediates

The requisite aldehyde partners are either commercially available or can be derived by alkylation with alkyl halides, alkyl mesylates, alkyl tosylates or alcohols containing any  
10 other suitable leaving group in a polar solvent such as DMF or acetone and a suitable base (*e.g.*, Cs<sub>2</sub>CO<sub>3</sub>, K<sub>2</sub>CO<sub>3</sub>) at room temperature or elevated temperatures, by Mitsunobu reaction with alcohols activated by a mixture of triphenylphosphine and diethylazodicarboxylate, or by analogous alkylation of the phenolic carboxylic esters or acids of formula 22 (Scheme 9, step a). Reduction of the esters of formula 23 by a  
15 suitable reducing agent (*e.g.*, diisobutylaluminium hydride at low temperature, with LiAlH<sub>4</sub> at elevated or ambient temperature) in a solvent such as THF provides the corresponding benzylalcohols of formula 24 (Scheme 9, step b). These can then be oxidized to the aldehydes of formula 25, preferably with activated MnO<sub>2</sub> as oxidant in dichloromethane (Scheme 9, step c).

Alternatively the introduction of the side-chain can be accomplished by direct alkylation (sequential for unsymmetrical compounds) of the phenolic benzaldehydes of formula 26 providing the desired compounds of formula 25 directly (Scheme 9, step d).

- 5 A further well-established route towards the synthesis of benzylaldehydes of formula 28 consists in the reduction of the corresponding benzonitriles of formula 27 by a suitable reducing agent such as diisobutylaluminium hydride at low temperature in a non-protic polar solvent (*e.g.*, THF; Scheme 9, step e).

Additional syntheses of aldehydes of formula III are described in the examples.

Scheme 9

As described hereinbefore, it has been found that the compounds of formula I possess pharmaceutical activity, in particular they are modulators of somatostatin receptor activity. More particularly, the compounds of the present invention have been found to be antagonists of the somatostatin receptor subtype 5 (SSTR5).

The following tests were carried out in order to determine the activity of the compounds of formula I.

A CHO cell line stably transfected with a plasmid encoding the human subtype 5 somatostatin receptor (GenBank accession number D16827) was obtained from  
5 Euroscreen. Cells were cultured and used for binding and functional assays.

Membranes of these cells were prepared by sonication in the presence of protease inhibitors and subsequent fractionating centrifugation. The protein concentration in the membrane preparation was determined using a commercial kit (BCA kit, Pierce, USA). Membranes were stored at  $-80^{\circ}\text{C}$  until use. After thawing, membranes were diluted in  
10 assay buffer (50 mM Tris-HCl at pH 7.4, 5 mM  $\text{MgCl}_2$  and 0.20 % BSA) and subjected to dounce homogenization.

For binding studies, 0.1 mL membrane suspension, corresponding to app.  $6 \times 10^{-15}$  mol receptor, was incubated for 1 h at room temperature with 0.05 nM  $^{125}\text{I}$ -labeled tracer (11-Tyr somatostatin-14, Perkin-Elmer) and either test compounds in varying  
15 concentrations or, for the determination of non-specific binding, 0.001 mM non-labeled somatostatin-14. The incubation was stopped by filtration through GF/B glassfiber filters and washing with ice-cold wash buffer (50 mM Tris-HCl at pH 7.4). The bound radioactivity was measured after application of a scintillation cocktail (Microscint 40) and expressed as disintegrations per minute (dpm).

20 The receptor concentration was determined in a prior saturation experiment where a fixed, arbitrary amount of membranes was incubated with a concentration range of radio-labeled tracer. This allows estimating the total number of specific binding sites per amount of protein (*i.e.*,  $B_{\text{max}}$ ), typically between 1 and 5 pmol/mg.

The concentration of the test compound required to result in half maximal  
25 inhibition of binding of the radio-labeled tracer ( $\text{IC}_{50}$ ) was estimated from a concentration-versus-dpm graph. The binding affinity ( $K_i$ ) was calculated from the  $\text{IC}_{50}$  by applying the Cheng-Prussoff equation for single binding sites.

For functional experiments, 50'000 cells were incubated in Krebs Ringer HEPES buffer (115 mM NaCl, 4.7 mM KCl, 2.56 mM  $\text{CaCl}_2$ , 1.2 mM  $\text{KH}_2\text{PO}_4$ , 1.2 mM  $\text{MgSO}_4$ ,  
30 20 mM  $\text{NaHCO}_3$  and 16 mM HEPES, adjusted to pH 7.4) supplemented with 1 mM IBMX and 0.1% BSA, then stimulated with 0.004 mM forskolin. Simultaneously with forskolin, test compounds in varying concentrations were applied. Cells were then incubated for 20 minutes at  $37^{\circ}\text{C}$  and 5%  $\text{CO}_2$ . Subsequently, cells were lysed and

cAMP concentration measured using a fluorescence-based commercial kit according to the manufacturer (HitHunter cAMP, DiscoverX).

The concentration of the test compound to induce a half maximal effect (*i.e.*, EC<sub>50</sub>) as well as the efficacy as compared to 0.15 nM somatostatin-14 were determined from concentration-versus-fluorescence (arbitrary units) graphs. For the determination of potential antagonism, 0.15 nM somatostatin-14 was applied together with the test compounds and the concentration of the test compounds to half maximally reverse the effect of somatostatin-14 (*i.e.*, IC<sub>50</sub>) were deduced from concentration-versus-fluorescence graphs.

The compounds of the present invention exhibit K<sub>i</sub> values of 0.1 nM to 10 µM, preferably K<sub>i</sub> values of 1 nM to 500 nM and more preferably 0.1 nM to 100 nM for human subtype 5 somatostatin receptor. The following table shows measured values for selected compounds of the present invention.

| Example 8   | 490                              |
| Example 137 | 6.4                              |

The compounds of formula I and their pharmaceutically acceptable salts and esters can be used as medicaments, *e.g.*, in the form of pharmaceutical preparations for enteral, parenteral or topical administration. They can be administered, for example, perorally, *e.g.*, in the form of tablets, coated tablets, dragées, hard and soft gelatine capsules, solutions, emulsions or suspensions, rectally, *e.g.*, in the form of suppositories, parenterally, *e.g.*, in the form of injection solutions or infusion solutions, or topically, *e.g.*, in the form of ointments, creams or oils.

The production of the pharmaceutical preparations can be effected in a manner which will be familiar to any person skilled in the art by bringing the described compounds of formula I and their pharmaceutically acceptable, into a galenical administration form together with suitable, non-toxic, inert, therapeutically compatible solid or liquid carrier materials and, if desired, usual pharmaceutical adjuvants.

Suitable carrier materials are not only inorganic carrier materials, but also organic carrier materials. Thus, for example, lactose, corn starch or derivatives thereof, talc, stearic acid or its salts can be used as carrier materials for tablets, coated tablets, dragées and hard gelatine capsules. Suitable carrier materials for soft gelatine capsules are, for example, vegetable oils, waxes, fats and semi-solid and liquid polyols (depending on the nature of the active ingredient no carriers are, however, required in the case of soft gelatine capsules). Suitable carrier materials for the production of solutions and syrups are, for example, water, polyols, sucrose, invert sugar and the like. Suitable carrier materials for injection solutions are, for example, water, alcohols, polyols, glycerol and vegetable oils. Suitable carrier materials for suppositories are, for example, natural or hardened oils, waxes, fats and semi-liquid or liquid polyols. Suitable carrier materials for topical preparations are glycerides, semi-synthetic and synthetic glycerides, hydrogenated oils, liquid waxes, liquid paraffins, liquid fatty alcohols, sterols, polyethylene glycols and cellulose derivatives.

Usual stabilizers, preservatives, wetting and emulsifying agents, consistency-improving agents, flavour-improving agents, salts for varying the osmotic pressure, buffer substances, solubilizers, colorants and masking agents and antioxidants come into consideration as pharmaceutical adjuvants.

The dosage of the compounds of formula I can vary within wide limits depending on the disease to be controlled, the age and the individual condition of the patient and the mode of administration, and will, of course, be fitted to the individual requirements in each particular case. For adult patients a daily dosage of about 1 mg to about 1000 mg, especially about 1 mg to about 100 mg, comes into consideration. Depending on the dosage it is convenient to administer the daily dosage in several dosage units.

The pharmaceutical preparations conveniently contain about 0.1-500 mg, preferably 0.5-100 mg, of a compound of formula I.

The present invention will be further explained by reference to the following illustrative examples. They are, however, not intended to limit its scope in any manner.

## Example 315

{4-[1-(3,5-Diethoxy-4-fluoro-benzyl)-piperidin-4-ylamino]-6-methoxy-[1,3,5]triazin-2-ylamino}-acetic acid

- 5 To a stirred solution of {4-[1-(3,5-diethoxy-4-fluoro-benzyl)-piperidin-4-ylamino]-6-methoxy-[1,3,5]triazin-2-ylamino}-acetic acid *tert*-butyl ester (0.09 g, 0.2 mmol, 1.0 equiv; example 297) in THF/methanol (1:1) (4 mL) was added drop by drop a 1 M solution of LiOH in water (0.42 mL, 0.42 mmol, 2.1 equiv). After 16 h, the reaction mixture was poured into ice water, the pH adjusted to 3-4 with diluted HCl and the
- 10 mixture extracted three times with dichloromethane/isopropanol (4:1). The combined organic layers were concentrated by evaporation under reduced pressure to yield 0.031 g (32%) of the title compound as a colorless solid. MS (ISN): 477.2 [M-H]<sup>-</sup>.

## Examples 316 and 317

- 15 According to the procedure described for the synthesis of example 315 further triazine derivatives have been synthesized from {4-[1-(4-chloro-3,5-diethoxy-benzyl)-piperidin-4-ylamino]-6-methoxy-[1,3,5]triazin-2-ylamino}-acetic acid *tert*-butyl ester (example 298) and from {4-[1-(2,6-diethoxy-4'-fluoro-biphenyl-4-ylmethyl)-piperidin-4-ylamino]-6-methoxy-[1,3,5]triazin-2-ylamino}-acetic acid *tert*-butyl ester (example 299) as indicated in Table 5. The results are compiled in Table 5 and comprise example
- 20 316 and example 317.
