4-AMINOPYRIDINE DERIVATIVES

Background of the Invention

The present invention relates to 4-aminopyridine derivatives. The compounds of the present invention inhibit brain acetylcholinesterase and are useful in the treatment of Alzheimer's disease.

Tetrahydroaminoacridine, which has anticholinesterase activity, has been reported to produce improved performance in psychological tests in patients afflicted with Alzheimer's disease (W. K. Summers et al., The New England Journal of Medicine, 315, 1241-1245 (1986)). The anticholinesterase phystostigmine has also been reportedly used in the experimental treatment of Alzheimer's disease (S. D. Brinkman et al., Neurobiol. Aging, 4, 139-145 (1983)).

The compounds described in the following four documents are alleged to have anticholinesterase activity:

United States Patent 4,631,286 refers to 9-amino-1,2,3,4-tetrahydroacridine-1-ol and related compounds for treating Alzheimer's disease.

United States Patent 4,550,113 refers to 9-amino-2,3,5,6,7,8-hexahydro-1H-cyclopenta(b)quinoline monohydrate hydrochloride for treating neuritis, injuries of the peripheral nervous system, hereditary neuromuscular diseases, and disseminated sclerosis.

United States Patent 4,540,564 refers to dihydropyridines for delivering drugs to the brain.

G. K. Patnaik et al., J. Med. Chem., 9, 483-488 (1966), refer to 4-substituted 2,3-polyethylene-quinolines having analgetic, local anesthetic, analeptic, and respiratory stimulant activities.

British Patent Specifications 1,186,061, 1,186,062, and 1,186,063 refer to benzonaphthyridine derivatives.

**Detailed Description of the Invention**

Compounds of the present invention may be prepared as described below.

**Scheme I**

![Chemical Diagram](image-url)
As shown in Scheme I, an aminonitrile of the formula II, wherein A is as defined above, is reacted with a ketone of the formula III wherein B is as defined above to prepare a ketimine of the formula IV.

The reaction is conducted in an inert solvent, preferably an aromatic solvent (e.g., benzene or toluene), in the presence of an acid, preferably a strong acid (e.g. p-toluenesulfonic acid). The temperature should be at least about 100°C, but is otherwise not critical. Generally, the reaction is conducted at the reflux temperature of the reaction mixture, e.g., by refluxing the reaction mixture in a Dean Stark apparatus, preferably for about 6 to about 16 hours, and removing the water periodically. The reaction pressure is not critical. Generally, the reaction will be conducted at a pressure of about 0.5 to about 2 atmospheres, preferably at ambient pressure (generally, about 1 atmosphere).

The crude ketimine IV obtained after the removal of solvent is then reacted with a base (e.g., lithium diisopropylamide) in an inert solvent, preferably an anhydrous ether (e.g., tetrahydrofuran), at a temperature of about 0°C to about 25°C. The reaction pressure is not critical. Generally, the reaction will be conducted at a pressure of about 0.5 to about 2 atmospheres, preferably at ambient pressure (generally, about 1 atmosphere).

The first method works especially well when an all carbon ketone is employed in the reaction. Azeotropic removal (80°C, PTSA, 15 hours) of water from a benzene solution of norcamphor (or an all carbon ketone) and anthranilonitrile afforded the corresponding ketimine which on treatment with lithium diisopropylamide (0°C, 4 hours) in tetrahydrofuran afforded the compound of Example 1 in 25% yield. The use of this procedure is
also exemplified by the preparation of the compounds of Examples 2, 3, 4, 30 and 36.

The limitation in the general applicability of the first method is the difficulty of formation of ketimines from carbonyl compounds containing a nitrogen or oxygen atom. Titanium (IV) chloride, because of its high affinity for oxygen, has been used in the preparation of ketimines. (See H. Weingarten et al., J. Org. Chem., 32, 3246 (1967)). This observation was adapted for the synthesis of 9-amino-1,2,3,4-tetrahydroacridine derivatives in a single step by the condensation of appropriate o-aminonitriles with diverse carbonyl components.

Thus, in a second method for preparing compounds of the present invention, a compound of the formula II wherein A is defined as above is reacted with a carbonyl-containing compound of the formula III wherein B is as defined above. The carbonyl-containing compound may be a ketone, a lactone, or the like. The reaction is conducted in an inert solvent in the presence of a Lewis acid (e.g., titanium (IV) chloride) and, if necessary, in the presence of a base, preferably an amine base (e.g. triethylamine). Suitable solvents include aromatic solvents (e.g., benzene or toluene) and chlorinated solvents (e.g., methylene chloride or 1,2-dichloroethane). The reaction temperature should be at least about 0°C and is preferably about 25 to about 120°C. The reaction pressure is not critical. Generally, the reaction will be conducted at a pressure of about 0.5 to about 2 atmospheres, preferably at ambient pressure (generally, about 1 atmosphere).

Thus, for example, condensation of delta-valerolactone with anthranilonitrile in methylene chloride by titanium (IV) chloride at 25°C in the
presence of triethylamine (2 equivalents) afforded the compound of Example 7 (28%). This method was adopted for the synthesis of the compounds of Examples 7-19, 26-29, 31-33, 35 and 37-46. The compounds of Examples 5 and 6 were prepared by condensing anthranilonitrile with the appropriate ketones in the presence of anhydrous zinc chloride at elevated temperature (<140°C).

Monoalkylation of the amine group in compounds of the present invention may be achieved by heating them with appropriate alkyl halides in the presence of sodium hydride in dimethylformamide. This is exemplified by the synthesis of the compounds of Examples 20-25 and 34.

The compounds of Formula I are capable of forming acid addition salts with pharmaceutically acceptable acids. The acid addition salts may be prepared by reacting the base form of the appropriate compound of formula I with one or more equivalents, preferably with an excess, of the appropriate acid in an organic solvent, for example, diethyl ether or an ethanol-diethyl ether mixture. Suitable acids to form these salts include the common mineral acids, e.g. hydrohalic, sulfuric or phosphoric acid; the organic acids, e.g. ascorbic, citric, lactic, aspartic or tartaric acid or their aqueous solutions whose pH has been adjusted to 5.5 or less; and acids which are sparingly soluble in body fluids and which impart slow-release properties to their respective salts, e.g. pamoic or tannic acid or carboxymethyl cellulose. The preferred salt is the hydrochloride salt.

The compounds of formula I and the pharmaceutically acceptable salts thereof are useful in the treatment of various memory dysfunctions associated with decreased cholinergic function such as Alzheimer's Disease. Additionally, the compounds lead to stimula-
tion of neuromuscular transmission, enhancement of excitation in excitable tissues (nerve, and smooth and striated muscle) as well as restoration of conductance in nerves and neuromuscular synapses in the case of injury thereof. The compounds of this invention also exhibit antidepressant activities which is particularly helpful for patients suffering from Alzheimer's Disease. The compounds of this invention are, in general, less toxic and have a broader therapeutic window than known compounds such as tacrine and physostigmine, making them therapeutically preferred.

In treating Alzheimer's disease, the dosage of the compounds of the present invention will vary with the form of administration and the particular compound chosen. Furthermore, it will vary with the particular subject as well as the age, weight and condition of the subject under treatment as well as with the nature and extent of the symptoms. Generally, however, a dose in the range of about 1 to about 300 mg/day, taken in single or divided doses, will be administered. The preferred dose is in the range of from about 1 to about 150 mg/day in single or divided doses.

Generally, treatment is initiated with small dosages substantially less than the optimum dose of the compound. Thereafter, the dosage is increased by small increments until the optimum effect under the circumstances is reached.

The compounds of the present invention are used alone or in combination with pharmacologically acceptable carriers, the proportion of which is determined by the solubility and chemical nature of the compound, chosen route of administration and standard medical practice. For example, they are administered orally in the form of capsules, tablets, suspensions or solutions or they may be injected parenterally.
Capsules and tablets are the preferred mode of administration. For parenteral administration, they can be used in the form of a sterile solution containing other solutes, for example, enough saline or glucose to make the solution isotonic.

Capsule and tablet compositions may contain the active ingredient in admixture with one or more pharmaceutical excipients suitable for the manufacture of capsules and tablets. Suitable pharmaceutical excipients are, for example, starch, milk sugar, and certain types of clay. The tablets can be uncoated or they can be coated by known techniques so as to delay disintegration and absorption in the gastrointestinal tract and thereby provide a sustained action over a longer period.

Aqueous suspensions of the compounds of formula I contain the active ingredient in admixture with one or more pharmaceutical excipients suitable for the manufacture of aqueous suspensions. Suitable excipients are, for example, methylcellulose, sodium alginate, gum acacia, lecithin and so forth. Aqueous suspensions can also contain one or more preservatives, one or more coloring agents, one or more flavoring agents and one or more sweetening agents.

Non-aqueous suspensions can be formulated by suspending the active ingredient in a vegetable oil for example, arachis oil, olive oil, sesame oil, or coconut oil, or in mineral oil, for example liquid paraffin, and the suspension may contain a thickening agent, for example beeswax, hard paraffin or cetyl alcohol. These compositions can also contain a sweetening agent, flavoring agent and antioxidant.

The following examples illustrate the preparation and properties of the compounds of the present invention. All melting points are uncorrected. Thin
layer chromatography (TLC) was conducted on silica gel.

Example 1

9-Amino-1,2,3,4-tetrahydro-1,4-methanoacridine

A solution of anthranilonitrile (3.6 g, 30.0 mmole), norcamphor (3.3 g, 30.0 mmole) and para-toluene sulfonic acid (50 mg) in benzene (50 ml) was heated to reflux using a Dean Stark apparatus. After heating for 18 hours, the reaction mixture was then cooled (25°C) and the separated water (about 1.5 ml) was withdrawn. The excess benzene was then removed under vacuum (1 mm Hg, 15 minutes). The oily residue thus obtained was dissolved in tetrahydrofuran (THF, 10 ml) and was cooled to 0°C and a solution of lithium diisopropylamide in THF (1M, 36 ml, 36 mmole) was then added. This reaction mixture was then stirred at 0°C for 3 hours. At the end of this period, the reaction mixture was quenched with 40 ml of water and was extracted with methylene chloride (200 ml). The resulting organic phase was washed with water (2 x 50 ml) and dried (anhydrous MgSO₄). The methylene chloride was removed under vacuum to afford a residue which was loaded on a silica gel flash chromatography column. V. OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSearchABLE

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1. Claim numbers , because they relate to subject matter not required to be searched by this Authority, namely:

2. Claim numbers , because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out specifically:

3. Claim numbers , because they are dependent claims not drafted in accordance with the second and third sentences of PCT Rule 6.4 (a).

VI. OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING

This International Searching Authority found multiple inventions in this international application as follows:

1. Claims 1-16, 23, and 25-27 (partial) drawn to oxazinoacridines and thieno and furoquinolines

1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.

2. As some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:

3. There were no required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers: 1-16, 23 and 25-27 (partial)

4. As all searchable claims could be searched without effort justifying an additional fee, the International Searching Authority did not invite payment of any additional fee.

Remedy:

☐ The additional search fees were accompanied by applicant's protest.

☐ No protest accompanied the payment of additional search fees.
