Title: STABLE PHARMACEUTICAL COMPOSITIONS COMPRISING MICAFUNGIN

Abstract: The present invention relates to a stable pharmaceutical composition comprising micafungin, to a process for the manufacture of said pharmaceutical composition as well as to its use in the treatment of fungal infections and/or conditions arising from said infections.
STABLE PHARMACEUTICAL COMPOSITIONS COMPRISING MICAFUNGIN

The present invention relates to a stable pharmaceutical composition comprising micafungin, to a process for the manufacture of said pharmaceutical composition as well as to its use in the treatment of fungal infections and/or conditions arising from said infections.

STATE OF THE ART

Invasive fungal infections (IFIs) are a frequent cause of morbidity and mortality in high-risk patients, such as immunocompromised patients. The number of such patients has increased in recent years due to increases in the use of intensive cancer chemotherapy as well as immunosuppressive regimens for autoimmune disease, the occurrence of solid organ and bone marrow transplantation, and the incidence of individuals with diseases of the immune system such as AIDS.

Candida is currently the predominant fungal pathogen in these patient populations. However, invasive aspergillosis has been increasing in incidence and Aspergillus is a significant fungal pathogen in bone marrow transplant recipients. Organisms belonging to both genera are associated with significant morbidity and a high mortality. Current therapies are not sufficient and treatment alternatives for this indication are urgently needed.

Micafungin (FK463), manufactured by Astellas Pharma Co., Ltd., is a water-soluble semisynthetic compound belonging to the new class of antifungal agents, the echinocandin lipopeptides. It is represented by the formula (I):
Micafungin is synthesised through the chemical modification of a fermentation product from Coleophoma empetri F-1 1899. It acts by selectively inhibiting 1,3-beta-D-glucan synthase, which is required for fungal cell wall synthesis. Micafungin was firstly marketed in Japan in 2002, and approved by FDA and marketed in US in May 2005. Clinical test has demonstrated that micafungin is very efficient for treating Candida and Aspergillus, and can be used as first-line medicine for treating diseases caused by Candida infections.

Echinocandins are inhibitors of fungal cell wall biosynthesis. Echinocandins exert their effect by disrupting the synthesis of 1,3-beta-D-glucan, an integral component of the fungal cell wall. Their mechanism of action differs from those of established classes of widely used systemic antifungal agents, which affect cell membrane sterols, either by direct interaction with them (polyenes, represented by amphotericin B) or through inhibition of sterol synthesis (e.g. azoles, including fluconazole, itraconazole and voriconazole), or interfere with nucleic acid metabolism (flucytosine). Echinocandins, including micafungin, are expected to show no cross-resistance to other antifungal agents.

Parenteral (ip) formulations of pharmaceutical drugs may be administered to patients via intramuscular (im), intravenous (iv) or subcutaneous methodology. The formulation that is developed for a particular drug is dependent on a variety of issues. If freeze-dried, the formulation should be capable of forming a well-formed
cake and readily reconstitutable (usually in less than one minute). Finally, the formulation should have an acceptable appearance and be prepared from generally accepted, safe excipients.

Stability is an important consideration when designing a formulation. For practical reasons, it must be possible to store the formulation for at least two years. Therefore, it is often desirable to freeze dry the formulation to achieve better shelf-life and storage at room temperature.

The instability and poor water solubility (<0.1 mg/ml) of the echinocandin compounds make them particularly difficult to formulate. Most of the formulations tested to date have a shelf life of less than one year.

Micafungin is sensitive to high temperature, high humidity and exposure to light. This entails a further challenge in formulating an ip formulation containing said echinocandin compound. Therefore, there is a need for a formulation that improves the stability of the compound and the salts thereof.

EP1 107777B1 discloses a stable pharmaceutical composition of micafungin in lyophilized form comprising lactose or maltose or sucrose as stabilizing agent. WO2012103801 discloses a pharmaceutical composition comprising micafungin and trehalose as stabilizing agent. WO2014173205 relates to a micafungin composition comprising a polysaccharide or disaccharide and which optionally may contain an appropriate amount of pH adjuster. However, none of these pharmaceutical compositions are ideal in stability.

Mycamine® is used for treatment of invasive candidiasis. Each vial of Mycamine® contains micafungin sodium as active substance and is presented as powder for solution for infusion. Before administration to a patient, the lyophilized product is reconstituted by adding a diluent and the desired amount of the diluted mixture is transferred to an infusion bag to be administered to the patient in need thereof.

Therefore, there is a need for stable pharmaceutical compositions comprising micafungin with low formation of impurities during storage. Moreover, it would be desirable to provide compositions having a good stability and a long shelf-life and which may be manufactured by a simple and fast method.
DESCRIPTION OF THE INVENTION

The present invention provides a stable pharmaceutical composition comprising micafungin or a pharmaceutically acceptable salt thereof. It has been found that having a water content below 2.0% can stabilize micafungin pharmaceutical compositions. The inventors have surprisingly found that an antifungal composition according to the present invention comprising micafungin or a pharmaceutically acceptable salt thereof, wherein the water content of the lyophilised cake or powder is below 2.0 % by weight of the total amount of the lyophilised cake or powder, result in a pharmaceutical composition with low formation of degradation products during storage.

Micafungin is easily degraded by oxidation, acid, base, water and photolytic degradation, so it is necessary to provide compositions comprising said active agent which are stable. The present invention provides a highly stable composition both in lyophilised form and as a solution after reconstitution of the lyophilised cake or powder. Advantageously, lyophilised preparations are stable, can be stored and are easily reconstituted. Moreover, lyophilised preparations may be kept sterile and essentially free of insoluble matter.

In a first aspect, the present invention provides a pharmaceutical composition comprising micafungin or a pharmaceutically acceptable salt thereof in the form of a lyophilised cake or powder, wherein the water content of the lyophilised cake or powder is below 2.0 % by weight of the total amount of the lyophilised cake or powder.

The term "pharmaceutically acceptable" indicates that the substance or composition must be compatible chemically and/or toxicologically, with the other ingredients comprising a pharmaceutical composition, the mammal being treated therewith, and/or the route of administration of the composition.

In a preferred embodiment of the pharmaceutical composition of the first aspect, the water content of the lyophilised cake or powder is between 0.1 and 1.9 % by weight of the total amount of the lyophilised cake or powder, preferably is between 0.5 and 1.5 % by weight of the total amount of the lyophilised cake or powder.
The term "active ingredient" or "active agent" refers to a therapeutically active compound, as well as any prodrugs thereof and pharmaceutically acceptable salts, hydrates and solvates of the compound and the prodrugs.

The determination of water content is measured by the method described in European Pharmacopoeia 7.0th edition 2.5.12. (Water: Semi-micro determination). The European Pharmacopoeia (Ph. Eur.) specifies Karl Fischer volumetric titration to measure the water content of many solvents, chemicals and other substances.

Preservation of the active ingredient is possible because the greatly reduced water content inhibits the action of microorganisms and enzymes that would normally spoil or degrade said active ingredient.

In a preferred embodiment of the pharmaceutical composition of the first aspect, the pharmaceutical composition comprises at least one bulking agent. Preferably, it comprises between 30 and 85% by weight of the bulking agent or bulking agents in respect of the total amount of the pharmaceutical composition. More preferably, it comprises between 35 and 80% by weight of the bulking agent or bulking agents in respect of the total amount of the pharmaceutical composition. Even more preferably, it comprises between 40 and 70% by weight of the bulking agent or bulking agents in respect of the total amount of the pharmaceutical composition. In a preferred embodiment of the pharmaceutical composition of the first aspect, the bulking agent is selected from the group consisting of a saccharide such as glucose, mannose, galactose, ribose, fructose, trehalose, sucrose, lactose, raffinose, mannitol, maltose, inositol, or sorbitol; an oligomer such as cyclodextrin; a polymer such as glycogen, cellulose, starch, dextran, chitosan, hyaluronate, or polyvinylpyrrolidone; a protein such as gelatin or serum albumin; and a mixture thereof. Preferably, the bulking agent is selected from lactose, galactose, mannitol, trehalose and a mixture thereof. More preferably, the bulking agent is lactose. Even more preferably, the bulking agent is lactose monohydrate.
The term "bulking agent" refers to a pharmaceutically acceptable excipient which provides bulk to the formulation such that when unit dosage amounts of the solution are lyophilised in containers, such as sterile vials, the freeze-dried residue will be clearly discernible. Acceptable bulking agents include, but are not limited to, carbohydrates such as simple sugars such as dextrose, ribose, fructose and the like, alcohol sugars such as mannitol, inositol and sorbitol, disaccharides including sucrose and lactose, naturally occurring polymers such as starch, dextrans, chitosan, hyaluronate, proteins (e.g., gelatin and serum albumin) and glycogen, and synthetic monomers and polymers. Bulking agents for use in the present invention preferably also act as osmolytes (i.e., aid in making the liquid form of the formulation isotonic with normal human serum). The bulking agent may act as a stabilizing agent. The term "stabilizing agent" refers to a pharmaceutically acceptable excipient that enhances the chemical or physical stability of the active ingredient in the formulation. Suitable stabilizing agents include polyols (e.g., polyethylene and propylene glycols, and carbohydrates such as sucrose, trehalose, fructose, lactose and mannitol), amino acids and surfactants such as polysorbates and bile salts.

In a preferred embodiment of the pharmaceutical composition of the first aspect, the pharmaceutical composition further comprises a pH modifying agent or a mixture of pH modifying agents. Preferably, the pH modifying agent is an acid or a buffer. Preferably, the acid is citric acid, preferably anhydrous citric acid. The term "pH modifying agent" as used herein refers to an excipient capable of modifying the pH of the composition. The pH of the composition is that of the solution comprising micafungin or a pharmaceutically acceptable salt thereof before lyophilisation or after reconstitution of the lyophilised cake or powder.

In a preferred embodiment of the pharmaceutical composition of the first aspect, the micafungin is in amorphous form.

In a preferred embodiment of the pharmaceutical composition of the first aspect, the pharmaceutical composition comprises between 30 and 120 mg of micafungin as free base by unit dose. Preferably, the pharmaceutical composition comprises about 50 mg of micafungin as free base by unit dose or about 100 mg of micafungin as free base by unit dose. As used herein, the term "unit dose" or "unit dosage" refers to a physically discrete unit that contains a predetermined quantity of active
ingredient calculated to produce a desired therapeutic effect. The unit dose or unit dosage may be in the form of a vial, tablet, capsule, sachet, etc. referred to herein as a "unit dosage form".

In a further embodiment of the pharmaceutical composition of the first aspect, the lyophilized cake is suitable for reconstitution to form a liquid composition for parenteral, preferably intravenous, administration.

The compositions of the present invention result in low formation of total impurities during storage compared with lyophilized formulations with a higher content of water known in the art. The term "total impurities" as used herein means the total amount of impurities commonly present in a pharmaceutically acceptable micafungin product or a pharmaceutically active micafungin salt prepared according to methods for preparing micafungin or a salt thereof well known to the skilled person in the art. The total amount of impurities present may be measured by HPLC-analysis. The change in the total amount of impurities during storage may be presented as the sum of the area percentage of the total amount of impurities in a formulation to be analysed. The person skilled in the art is familiar with various applicable HPLC devices and methods for measuring the formation of impurities during storage.

The pharmaceutical compositions of the invention are stable. The term "stable" as used herein refers to a pharmaceutical composition comprising micafungin wherein the total content of impurities originating from the decomposition of micafungin does not exceed 5 % area, preferably 3 % area and more preferably 2 % area determined by liquid chromatography (HPLC) at 275 nm if such a composition is stored for 6 months at 5 °C. Further, the term "stable" as used herein for lyophilized forms, refers to a pharmaceutical composition which when reconstituted in a sterile liquid vehicle, the reconstituted solution is clear without precipitation of the water insoluble drug for at least 2 hours after addition of the sterile liquid vehicle.

Once lyophilized, the pharmaceutical compositions as herein disclosed are packaged (e.g. the vials are stoppered) and ready for storing and/or shipping to end users. For use, the lyophilized cake or powder is reconstituted by adding a suitable reconstitution solution. Then, the reconstituted composition is further diluted in a bag for intravenous administration.
Suitable sterile solutions for reconstitution of the lyophilizate form of the pharmaceutical compositions as herein disclosed are distilled and/or sterile water for injection, bacteriostatic water for injection optionally comprising methylparabene and/or propylparabene and/or saline, 5% glucose solution, 5% or 10% dextrose solution. Preferably, saline is 0.9% sodium chloride, or 0.45% or 0.225% solution of sodium chloride. Also, a solution of 0.45% sodium chloride and 2.5% dextrose can be used. Other suitable solutions can be 6% dextran in 5% dextrose or 6 to 10% hydroxyethyl starch solutions in sterile water for injection.

In a further embodiment of the pharmaceutical composition of the first aspect, the lyophilized cake of the present invention is reconstituted in a sterile aqueous solution, preferably the sterile aqueous solution is distilled and/or sterile water for injection, bacteriostatic water for injection optionally comprising saline, 5% glucose solution, 5% dextrose solution, Hartmann’s solution, Ringer’s solution and/or Ringer’s lactate solution, more preferably the sterile aqueous solution is saline or 5% glucose solution.

In a preferred embodiment of the pharmaceutical composition of the first aspect, the pH of the reconstituted pharmaceutical composition is between 3.0 and 8.0. Preferably, the pH of the reconstituted pharmaceutical composition is between 3.5 and 7.0. More preferably, the pH of the reconstituted pharmaceutical composition is between 4.5 and 6.0.

The determination of pH is measured by the method described in the European Pharmacopoeia 7.0th edition 2.2.3. (Potentiometric determination of pH). The pH is a number which represents conventionally the hydrogen ion concentration of an aqueous solution. The potentiometric determination of pH is made by measuring the potential difference between 2 appropriate electrodes immersed in the solution to be examined. A Crison pH meter GLP21 was used. This instrument uses a pH electrode sensor A.T.C. type Pt 1000, measures electric potential differences with a high entry impedance and high resolution. The instrument was calibrated before the first measurement and after each 15 measurements with 2 reference solutions having pH values of 4.00 and 7.02.

In a second aspect, the present invention provides a process for the manufacture of a pharmaceutical composition comprising micafungin, comprising at least the step of
dissolving micafungin in a water solution in a reactor made of a material other than glass.

The inventors have surprisingly found that the process for the manufacture of a pharmaceutical composition comprising micafungin avoiding the use of reactor made of glass is more consistent and robust in terms of reproducibility and minimizing losses. In the process of the second aspect, drug substance retention in the glass material is avoided and therefore the loss of said drug substance is minimized.

In a preferred embodiment of the process of the second aspect, the reactor material is selected from the group consisting of stainless steel, carbon steel, teflon, glass lined steel, high alloy steel and high alloys such as hastelloy, tantalum, inconel, monel, titanium, nickel and cupronickel, preferably the reactor is a stainless steel reactor.

The term "reactor" as used herein refers to a vessel in the chemical processing industries that is used for a variety of process operations, including: product mixing, chemical reactions, batch distillation, liquid extraction, polymerization, solids dissolution, and other forms of reaction, mixing, or catalyst functions. A reactor consists of a tank or body with an agitator and heating or cooling system. Vessels are usually fabricated with stainless steel, carbon steel, glass lined steel or high alloy steel depending on the corrosiveness of the chemicals or products being used.

In a preferred embodiment of the process of the second aspect, the process comprises at least the following steps:

i) preparing an aqueous solution of at least one pharmaceutically acceptable excipient in water in a reactor made of a material other than glass;

ii) optionally heating the solution of step (i) to a temperature between 35 °C and 45 °C to dissolve the pharmaceutically acceptable excipient;

iii) when appropriate, cooling the solution of step (i) or (ii) to a temperature between 5 °C and 15 °C to form a cooled solution;

iv) adding under stirrer agitation a pharmaceutically acceptable amount of micafungin to the solution obtained in step (i), (ii) or (iii);

v) optionally adjusting the pH of the solution obtained in step (iv) to a pH between 3.5 and 7.0 using a pharmaceutically acceptable amount of a pH
modifying agent;
vi) optionally filtering the solution obtained in step (iv) or (v);
vii) when appropriate, freezing the solution obtained in step (iv), (v) or (vi); and
viii) when appropriate, freeze drying the frozen solution obtained in step (vii).

In a preferred embodiment of the process of the second aspect, the pharmaceutically acceptable excipient in step (i) is lactose, more preferably lactose monohydrate and the pH modifying agent used in step (v) is selected from the group consisting of citric acid, NaOH and mixtures thereof. Preferably, the pH is adjusted to between 4.5 and 6.0 in step (v). More preferably, nitrogen gas is bubbled in the solution. Even more preferably, steps (vii) and/or (viii) are performed in a vial and the vial is sealed after freeze-drying under an inert atmosphere, preferably under nitrogen or argon atmosphere.

The composition according to the present invention is prepared by dissolving and mixing the ingredients, filtering the obtained mixture, and after transferring the solution to suitable vials. The so obtained solution is lyophilized to obtain a lyophilized cake. Lyophilization, also called freeze-drying, refers to a drying process by freezing a material dissolved in water below 0 °C and then reducing the surrounding pressure using a vacuum pump to allow the frozen water in the material to sublimate directly from the solid phase to the gas phase. The composition according to the present invention is preferably lyophilized in pharmaceutically acceptable vials according to the method of the present invention.

A third aspect of the present invention provides a process for the manufacture of a lyophilised cake or powder comprising micafungin or a pharmaceutically acceptable salt thereof, and at least one pharmaceutically acceptable excipient, wherein said process comprises the freeze drying of a solution comprising micafungin or a pharmaceutically acceptable salt thereof as active agent and at least one pharmaceutically acceptable excipient, wherein said freeze drying comprises the steps of freezing the solution, primary drying and secondary drying, and wherein the freeze drying is less than 50 hours long, preferably between 10 and 45 hours long, and more preferably between 25 and 40 hours long from the initial step of freezing the solution until the end of the secondary drying.

In a preferred embodiment of the process of the third aspect, the freeze drying
comprises the following steps:
i) freezing the solution at a temperature below -20 °C and maintaining said temperature for at least 1 hour;
ii) primary drying the frozen solution of step (i) under vacuum and at a temperature between -10 and 10 °C, and maintaining said conditions for at least 10 hours; and
iii) secondary drying the primary dried frozen solution of step (ii) under vacuum and at a temperature between 20 and 45 °C, and maintaining said conditions for at least 5 hours.

The lyophilisation (freeze-drying) process as disclosed herein comprises at least three steps: freezing, primary drying, and secondary drying. The lyophilisation process as herein disclosed provides a good quality of the resulting cake in the minimum time. This process maximizes the rate of heat transfer to each vial without causing cake collapse and avoiding slower reconstitution times. The freeze drying cycle is efficient and robust without compromising the pharmaceutical quality of the product and neither other parameters such as stability and water content.

The term "primary drying" refers to heating the material at low temperature and low pressure to cause frozen "free water" to sublimate directly to vapour. The term "secondary drying", also known as desorption drying, refers to further heating the material, so that the bound unfrozen water absorbs the heat of desorption and becomes free water, which then absorbs the heat of evaporation and becomes vapour, finally escaping from the material.

In a preferred embodiment, the temperature in step (i) is between -55 and -35 °C, preferably between -50 and -40 °C, maintained at least 2 hours, preferably between 2 and 4 hours. In a more preferred embodiment, the temperature in step (ii) is between -5 and 10 °C, maintained at least 12 hours, preferably between 15 and 25 hours. In a more preferred embodiment, the temperature in step (iii) is between 25 and 40 °C, maintained at least 7 hours, preferably between 8 and 16 hours. In a more preferred embodiment, the temperature in step (i) is between -55 and -35 °C, preferably between -50 and -40 °C, maintained at least 2 hours, preferably between 2 and 4 hours; and the temperature in step (ii) is between -5 and 10 °C, maintained at least 12 hours, preferably between 15 and 25 hours; and the temperature in step (iii) is between 25 and 40 °C, maintained at least 7 hours, preferably between 8 and 16 hours.
In a preferred embodiment, the vacuum in step (ii) ranges from 0.01 to 1 mbar, preferably from 0.05 to 0.5 mbar, more preferably from 0.1 to 0.2 mbar. In a preferred embodiment, the vacuum in step (iii) ranges from 0.005 to 0.1 mbar, preferably from 0.01 to 0.08 mbar, more preferably from 0.02 to 0.06 mbar.

In a preferred embodiment of the process of the second aspect, the freezing of step (vii) and the freeze drying of step (viii) are defined in the process of the third aspect.

In a further embodiment of the process of the second or third aspects, said processes are for the manufacture of the pharmaceutical composition of the first aspect.

In a fourth aspect, it is provided a pharmaceutical composition obtained by the process of the second or third aspects.

A fifth aspect of the present invention provides a pharmaceutical batch comprising 1,200 units of the pharmaceutical composition of the first or fourth aspect. Preferably, the pharmaceutical batch comprises at least 6,000 units.

Another aspect relates to the pharmaceutical composition of the first or fourth aspects, or the pharmaceutical batch of the fifth aspect, for use in the treatment of a fungal infection in a mammal.

The lyophilized composition is then appropriately sealed and stored (e.g., in stoppered vials) for later use. In a further embodiment, the vial as herein disclosed has a volume between 3 and 12 ml, preferably between 4 and 11 ml, more preferably it is a 10 ml vial. More preferably, the vial is capped with a rubber stopper and a seal.

The term "batch" as used herein refers to a specific quantity of a drug or other material that is intended to have uniform character and quality, within specified limits, and is produced according to a single manufacturing order during the same cycle of manufacture. A batch, in the case of a drug product produced by continuous process, is a specific identified amount produced in a unit of time or quantity in a manner that assures its having uniform character and quality within specified limits.
The term "pharmaceutical batch" as used herein refers to a batch as defined above of a pharmaceutical composition manufactured in accordance with the principles and guidelines of Good Manufacturing Practice (GMP) at an industrial scale and which is intended for commercialization (Directive 91/356/EEC).

The pharmaceutical composition may be manufactured at laboratory scale, not necessarily following GMP and not intended for commercialization. The pharmaceutical composition may also be manufactured for validation, following GMP. A batch of a pharmaceutical composition which is manufactured for validation is called "pilot batch".

Each pharmaceutical batch of finished product must fulfil the regulatory requirements of the corresponding Medicine Agency before being released for sale or supply, such as impurities thresholds and stability data.

The term "uniform" as used herein refers to the content of the active ingredient in the vials of a pharmaceutical batch has to be homogeneous. According to the FDA criteria, uniformity is considered as achieving 90-110 % potency of the theoretical strength with a relative standard deviation (RSD) of less than 5 % for all samples (Guidance for Industry ANDA's: Blend Uniformity Analysis, published August 1999).

A sixth aspect of the present invention provides a glass vial comprising the pharmaceutical composition of the first or fourth aspects.

In a seventh aspect, the present invention relates to a cardboard box with a patient information leaflet comprising at least one unit of the pharmaceutical composition of the first or fourth aspects or at least one vial of the sixth aspect.

In an eighth aspect, it is provided a method for preparing a pharmaceutical dossier to obtain the marketing authorization of pharmaceutical composition of the first or fourth aspects comprising the following steps:

i) manufacturing at least one pharmaceutical batch of the fifth aspect;

ii) performing stability tests of the batches of step (i);
iii) compiling the results obtained in steps (i) to (iii); and
iv) providing the compiled results of step (iii) in a data carrier.

In a ninth aspect, it is provided a data carrier comprising the compiled results of a pharmaceutical dossier obtained by the method of the eighth aspect.

The term "pharmaceutical dossier" to obtain the marketing authorization refers to a dossier with data proving that the drug has quality, efficacy and safety properties suitable for the intended use, additional administrative documents, samples of finished product or related substances and reagents necessary to perform analyzes of finished product as described in that dossier.

In a further embodiment of the data carrier of the eleventh aspect, the data carrier is selected from the group consisting of a digital data carrier such as CD, DVD, USB, hard drive; and paper.

The term "data carrier" refers to a device for recording (storing) information (data). Recording can be done using virtually any form of energy. A storage device may hold information, process information, or both. Most often the term is used with computers. Data carrier can permanently hold data, like files.

Unless otherwise indicated, all the analysis methods are carried out according to the European Pharmacopoeia 7th edition.

All percentages, parts and ratios herein disclosed are by weight unless specifically noted otherwise. As used herein, the term "about" refers preferably to a range that is +10 %, preferably +-5 %, or more preferably the value with which the term is associated.

EXAMPLES

The following examples illustrate various embodiments of the invention and are not intended to limit the invention in any way:

Example 1: preparation of stable micafungin compositions.
Lactose monohydrate was dissolved in 80 % of the total quantity of water for
injection under heating to 40 °C. The solution was stirred for about 10 minutes until complete dissolution in a stainless steel reactor. The solution was cooled below 15 °C and micafungin was added while stirring in a uniform speed to avoid foam formation. 1.025 ml of 0.76 % by weight of anhydrous citric acid of was added to the solution. The pH of the solution was then adjusted to between 4.5 and 6.0 with 0.384 % by weight of NaOH, and the volume of the solution was adjusted by adding the required amount of water for injection. The solution was sterile-filtered through a 0.22 μm pore size syringe filter. The solution was thereafter transferred to 10 ml lyophilisation vials and pre-stopped with sterile butyl rubber stoppers and a flip-off cap. The solution was then subjected to lyophilisation. The vial was wrapped with an UV-protective film.

(1) "q.s. to pH" means the addition of alkali in a quantity sufficient to bring the solution to a desired pH (e.g., q.s. to pH 4.5-6.0 means the addition of alkali to bring the solution to a pH of 4.5-6.0).

(2) "q.s." means adding a quantity sufficient to achieve a certain state (e.g., volume, i.e., to bring a solution to a desired volume).

* Vials were overfilled with 4 % to fill the vials with 4.36 ml of the filtered solution.

The compositions of examples 1a and 1b were prepared at the same time and subjected to the same lyophilisation cycle in order to minimize external factors that could affect the final composition.

Example 2: Lyophilization process

The compositions prepared in example 1a and 1b were subjected to lyophilization. Two batches of 350 vials/batch were lyophilized following the process described in
the embodiments of the description of the third aspect.
The freeze drying of the pharmaceutical compositions of the examples was performed at different temperatures, pressures and durations and it was found that good cakes with no collapse or cavities were obtained when the freeze drying took at least 16 hours and less than 50 hours, from the start of the freezing of the solution to the end of the secondary drying. Also, very good cakes were obtained when the solution was frozen at a temperature below -20 °C and when the primary drying was set at a temperature between -10 and 10 °C, and was maintained for at least 10 hours. Very good cakes were obtained when the secondary drying temperature was set between 20 and 40 °C, and maintained for at least 5 hours.

Example 3: Stability Studies for the compositions disclosed in example 1.
The compositions prepared according to examples 1a and 1b are tested for stability at time zero after lyophilisation and also are stored in the lyophilised state at 40 °C and 75 % of relative humidity (RH) for 3 months. Prior to testing, the lyophilised material was dissolved in a pharmaceutically acceptable reconstitution solution. The so obtained solutions were then analysed by HPLC according to standard methods well known to the skilled person in the art.

Example 4: Preparation of stable micafungin compositions.
Lactose monohydrate was dissolved in 80 % of the total quantity of water for injection under heating to 40 °C. The solution was stirred for about 10 minutes until complete dissolution in a reactor. The solution was cooled below 15 °C and micafungin was added while stirring in a uniform speed to avoid foam formation.

1.025 ml of 0.76 % by weight of anhydrous citric acid of was added to the solution. The pH of the solution was then adjusted to between 4.5 and 6.0 with 0.384 % by weight of NaOH, and the volume of the solution was adjusted by adding the required amount of water for injection. The solution was sterile-filtered through a 0.22 μm pore size syringe filter. The solution was thereafter transferred to 10 ml lyophilisation vials and pre-stopped with sterile butyl rubber stoppers and a flip-off cap. The solution was then subjected to lyophilisation as described in example 2. The vial was wrapped with an UV-protective film.

(1) "q.s. to pH" means the addition of alkali in a quantity sufficient to bring the solution to a desired pH (e.g., q.s. to pH 4.5-6.0 means the addition of alkali to bring the solution to a pH of 4.5-6.0).

(2) "q.s." means adding a quantity sufficient to achieve a certain state (e.g., volume, i.e., to bring a solution to a desired volume).

* Ex 4a: vials were overfilled with 6.3 % to fill the vials with 4.46 ml of the filtered solution.

* Ex 4b: vials were overfilled with 2.5 % to fill the vials with 4.30 ml of the filtered solution.

</tbody>
</table>

The compositions of examples 4a and 4b were prepared at the same time and subjected to the same lyophilisation cycle in order to minimize external factors that could affect the final composition. Assay (%) results in the pharmaceutical
composition prepared using a stainless steel reactor are more consistent and robust in terms of reproducibility than the ones obtained in the pharmaceutical composition using a reactor of glass material. In the process using a reactor made of a material other than glass, drug substance retention in the glass material is avoided and therefore the loss of said drug substance is minimized.

**Example 5: Water content.**

The amount of water of the pharmaceutical compositions as herein disclosed was measured by Karl Fisher titration.

CLAIMS

1.- A pharmaceutical composition comprising micafungin or a pharmaceutically acceptable salt thereof in the form of a lyophilised cake or powder, wherein the water content of the lyophilised cake or powder is below 2.0 % by weight of the total amount of the lyophilised cake or powder.

2.- The pharmaceutical composition according to the preceding claim, wherein the water content of the lyophilised cake or powder is between 0.1 and 1.9 % by weight of the total amount of the lyophilised cake or powder.

3.- The pharmaceutical composition according to any one of the preceding claims, wherein the water content of the lyophilised cake or powder is between 0.5 and 1.5 % by weight of the total amount of the lyophilised cake or powder.

4.- The pharmaceutical composition according to any one of the preceding claims, comprising at least one bulking agent.

5.- The pharmaceutical composition according to the preceding claim, comprising between 30 and 85 % by weight of the bulking agent or bulking agents in respect of the total amount of the pharmaceutical composition.

6.- The pharmaceutical composition according to any one of the two preceding claims, comprising between 35 and 80 % by weight of the bulking agent or bulking agents in respect of the total amount of the pharmaceutical composition.

7.- The pharmaceutical composition according to any one of the three preceding claims, comprising between 40 and 70 % by weight of the bulking agent or bulking agents in respect of the total amount of the pharmaceutical composition.

8.- The pharmaceutical composition according to any one of the four preceding claims, wherein the bulking agent is selected from the group consisting of a saccharide such as glucose, mannose, galactose, ribose, fructose, trehalose, sucrose, lactose, raffinose, mannitol, maltose, inositol, or sorbitol; an oligomer such as cyclodextrin; a polymer such as glycogen, cellulose, starch, dextran, chitosan, hyaluronate, or polyvinylpyrrolidone; a protein such as gelatin or serum albumin; and
a mixture thereof.

9.- The pharmaceutical composition according to any one of the five preceding claims, wherein the bulking agent is selected from lactose, galactose, mannitol, trehalose and a mixture thereof.

10.- The pharmaceutical composition according to any one of the six preceding claims, wherein the bulking agent is lactose, preferably the bulking agent is lactose monohydrate.

11.- The pharmaceutical composition according to any one of the preceding claims, further comprising a pH modifying agent or a mixture of pH modifying agents.

12.- The pharmaceutical composition according to the preceding claim, wherein the pH modifying agent is an acid or a buffer.

13.- The pharmaceutical composition according to the preceding claim, wherein the acid is citric acid, preferably anhydrous citric acid.

14.- The pharmaceutical composition according to any one of the preceding claims, wherein the micafungin is in amorphous form.

15.- The pharmaceutical composition according to any one of the preceding claims, wherein the pharmaceutical composition comprises between 30 and 120 mg of micafungin as free base by unit dose.

16.- The pharmaceutical composition according to any one of the preceding claims, wherein the pharmaceutical composition comprises about 50 mg of micafungin as free base by unit dose or about 100 mg of micafungin as free base by unit dose.

17.- The pharmaceutical composition according to any one of the preceding claims, wherein said lyophilised cake or powder is suitable for reconstitution to form a liquid composition for parenteral, preferably intravenous, administration.

18.- The pharmaceutical composition comprising the lyophilized cake according to any one of the preceding claims reconstituted in a sterile aqueous solution.
19. - The pharmaceutical composition according to the preceding claim, wherein the sterile aqueous solution is distilled and/or sterile water for injection, bacteriostatic water for injection optionally comprising saline, 5% glucose solution, 5% dextrose solution, Hartmann's solution, Ringer's solution and/or Ringer's lactate solution.

20. - The pharmaceutical composition according to any one of the two preceding claims, wherein the sterile aqueous solution is saline or 5% glucose solution.

21. - The pharmaceutical composition according to any one of the three preceding claims, wherein the pH of the composition is between 3.0 and 8.0.

22. - The pharmaceutical composition according to any one of the four preceding claims, wherein the pH of the composition is between 3.5 and 7.0.

23. - The pharmaceutical composition according to any one of the five preceding claims, wherein the pH of the composition is between 4.5 and 6.0.

24. - A process for the manufacture of a pharmaceutical composition comprising micafungin, comprising at least the step of dissolving micafungin in a water solution in a reactor made of a material other than glass.

25. - The process according to the preceding claim, wherein the reactor material is selected from the group consisting of stainless steel, carbon steel, glass lined steel, high alloy steel and high alloys such as hastelloy, tantalum, inconel, monel, titanium, nickel and cupronickel, preferably the reactor is a stainless steel reactor.

26. - The process according to any one of the two preceding claims, comprising at least the following steps:
   i) preparing an aqueous solution of at least one pharmaceutically acceptable excipient in water in a reactor made of a material other than glass;
   ii) optionally heating the solution of step (i) to a temperature between 35 °C and 45 °C to dissolve the pharmaceutically acceptable excipient;
   iii) when appropriate, cooling the solution of step (i) or (ii) to a temperature between 5 °C and 15 °C to form a cooled solution;
   iv) adding under stirrer agitation a pharmaceutically acceptable amount of
micafungin to the solution obtained in step (i), (ii) or (iii);
v) optionally adjusting the pH of the solution obtained in step (iv) to a pH between
3.5 and 7.0 using a pharmaceutically acceptable amount of a pH modifying agent;
vi) optionally filtering the solution obtained in step (iv) or (v);
vii) when appropriate, freezing the solution obtained in step (iv), (v) or (vi); and
viii) when appropriate, freeze drying the frozen solution obtained in step (vii).

27.- The process according to the preceding claim, wherein the pharmaceutically
acceptable excipient in step (i) is lactose, more preferably lactose monohydrate and
the pH modifying agent used in step (v) is selected from the group consisting of citric
acid, NaOH and mixtures thereof.

28.- The process according to any one of the two preceding claims, wherein the pH
is adjusted to between 4.5 and 6.0 in step (v).

29.- The process according to any one of the three preceding claims, wherein
nitrogen gas is bubbled in the solution.

30.- The process according to any one of the four preceding claims, wherein steps
(vii) and/or (viii) are performed in a vial.

31.- The process according to the preceding claim, wherein the vial is sealed after
freeze-drying under an inert atmosphere, preferably under nitrogen or argon
atmosphere.

32.- A process for the manufacture of a lyophilised cake or powder comprising
micafungin or a pharmaceutically acceptable salt thereof, and at least one
pharmaceutically acceptable excipient, wherein said process comprises the freeze
drying of a solution comprising micafungin or a pharmaceutically acceptable salt
thereof as active agent and at least one pharmaceutically acceptable excipient,
wherein said freeze drying comprises the steps of freezing the solution, primary
drying and secondary drying, and wherein the freeze drying is less than 50 hours
long, preferably between 10 and 45 hours long, and more preferably between 25
and 40 hours long from the initial step of freezing the solution until the end of the
secondary drying.
33. - The process according to the preceding claim, wherein the freeze drying comprises the following steps:
i) freezing the solution at a temperature below \(-20\ ^\circ\text{C}\) and maintaining said temperature for at least 1 hour;
ii) primary drying the frozen solution of step (i) under vacuum and at a temperature between \(-10\) and \(10\ ^\circ\text{C}\), and maintaining said conditions for at least 10 hours; and
iii) secondary drying the primary dried frozen solution of step (ii) under vacuum and at a temperature between \(20\) and \(45\ ^\circ\text{C}\), and maintaining said conditions for at least 5 hours.

34. - The process according to any one of the two preceding claims, wherein the temperature in step (i) is between \(-55\) and \(-35\ ^\circ\text{C}\), preferably between \(-50\) and \(-40\ ^\circ\text{C}\), maintained at least 2 hours, preferably between 2 and 4 hours; and/or wherein the temperature in step (ii) is between \(-5\) and \(10\ ^\circ\text{C}\), maintained at least 12 hours, preferably between 15 and 25 hours; and/or wherein the temperature in step (iii) is between \(25\) and \(40\ ^\circ\text{C}\), maintained at least 7 hours, preferably between 8 and 16 hours.

35. - The process according to any one of the three preceding claims, wherein the vacuum in step (ii) ranges from 0.01 to 1 mbar, preferably from 0.05 to 0.5 mbar, more preferably from 0.1 to 0.2 mbar.

36. - The process according to any one of the four preceding claims, wherein the vacuum in step (iii) ranges from 0.005 to 0.1 mbar, preferably from 0.01 to 0.08 mbar, more preferably from 0.02 to 0.06 mbar.

37. - The process according to any one of claims 26 to 31, wherein the freezing of step (vii) and the freeze drying of step (viii) are as defined in any one of claims 32 to 36.

38. - The process according to any one of the process preceding claims for the manufacture of a pharmaceutical composition as defined in claims 1 to 23.

39. - A pharmaceutical composition obtained by the process as defined in claims 24 to 38.
40. - A pharmaceutical batch comprising at least 1,200 units of the pharmaceutical composition as defined in any one of claims 1 to 23 or in claim 39.

41. - The pharmaceutical batch according to the preceding claim, comprising at least 6,000 units.

42. - The pharmaceutical composition as defined in any one of claims 1 to 23 or in claim 39, or the pharmaceutical batch as defined in claims 40 or 41, for use in the treatment of a fungal infection in a mammal.

43. - A glass vial comprising the pharmaceutical composition as defined in any one of claims 1 to 23 or in claim 39.

44. - The vial according to the preceding claim, wherein the volume of said vial is between 3 and 12 ml, preferably between 4 and 11 ml, more preferably is a 10 ml vial.

45. - The vial according to any one of the two preceding claims, wherein said vial is capped with a rubber stopper and a seal.

46. - A cardboard box with a patient information leaflet comprising at least one unit of the pharmaceutical composition as defined in claims 1 to 23 or in claim 39 or at least one vial as defined in claims 43 to 45.

47. - A method for preparing a pharmaceutical dossier to obtain the marketing authorization of pharmaceutical composition as defined in any one of claims 1 to 23 or in claim 39 comprising the following steps:
   i) manufacturing at least one pharmaceutical batch as defined in any one of claims 40 or 41;
   ii) performing stability tests of the batches of step (i);
   iii) compiling the results obtained in steps (i) and (ii); and
   iv) providing the compiled results of step (iii) in a data carrier.

48. - A data carrier comprising the compiled results of a pharmaceutical dossier obtained by the method of the preceding claim.
49.- The data carrier according to the preceding claim, wherein said data carrier is selected from the group consisting of a digital data carrier such as CD, DVD, USB, hard drive; and paper.
### A. Classification of Subject Matter

INV. A61K9/00 A61K31/00 A61P31/10

ADD.
According to International Patent Classification (IPC) or to both national classification and IPC

### B. Fields Searched

Minimum documentation searched (classification system followed by classification symbols)

A61K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

EPO-Internal

### C. Documents Considered to be Relevant
