AMINOALKOXY-FUNCTIONAL CHALCONES

FIELD OF THE INVENTION

The present invention relates to a novel class of chalcone derivatives and analogues thereto as well as to use of a class of chalcone derivatives as pharmaceutically active agents, in particular against bacterial and parasitic infections.

Furthermore, the invention relates to a method of predicting whether a chemical compound has a potential inhibitory effect against an organism such as Helicobacter pylori and Plasmodium falciparum. The prediction is based on the ability of the chemical compound to act as an inhibitor of the enzyme dihydroorotate dehydrogenase which is involved in the synthesis of pyrimidine in prokaryotic as well as eukaryotic cells such as bacteria, parasites, fungi, helminths and any type of mammalian cells such as human cells.

BACKGROUND OF THE INVENTION

Chalcones, e.g., for use against parasitic infections are known from earlier patent applications assigned to the applicant, e.g. WO 93/17671 and WO 99/00114. Moderate antibacterial activity has been reported for a limited number of chalcones in earlier publications, e.g. Haraguchi, H. et al Phytochemistry 1998, 48, 125-129 and Hatano, T. et al Chem. Pharm. Bull (Tokyo) 2000,48, 1286-92.

The bioavailability of several of the known chalcones is low due to the low solubility of the compounds. The compounds do not typically dissolve in the intestine and are therefore not available for absorption.

The spread of antimicrobial resistance determinants particular among nosocomial bacterial pathogens is an increasing problem. Such resistant pathogens include Staphylococcus aureus resistant to methicillin and thus to all β-lactam-antibiotics and Enterococci resistant to vancomycin (VRE). Such resistant bacteria pose a significant therapeutic challenge and bacterial strains resistant to all currently available antimicrobials are emerging. Furthermore, bacterial species intrinsically resistant to commonly employed antimicrobials are being recognized as important opportunistic pathogens in the setting of long-term immunocompromized patients. An example of this is Stenotrophomonas maltophilia which possesses a β-lactamase rendering the bacteria intrinsically resistant to carbapenem. As cross-resistance within a given class of antibiotics often occurs the development of new classes of antibiotics is a necessity to counter the emerging threat of bacterial resistance.

The resistance of Plasmodium falciparum to chloroquine and other antimalarial drugs have created an urgent need for new drugs that are safe and effective for the prophylaxis and treatment of malaria.

Furthermore, the increasing appearance of resistance to first line antileishmanial drugs, e.g. Pentostam or Glucantime, emphasizes the need for new drugs for the treatment of Leishmania infections.

SUBSTITUTE SHEET (RULE 26)
Thus, there is a need for chalcone derivatives with improved therapeutic or prophylactic activities against parasites and bacteria.

**BRIEF DESCRIPTION OF THE FIGURES**

Figure 1 illustrates the general synthetic scheme for the preparation of aminoalkoxy-functional chalcones where the aromatic rings are phenyl rings. $R^1$, $R^2$ and $Z$ are as defined herein.

Figure 2 illustrates a time-kill curve of C023 against S.aureus ATCC33591. Bacterial growth is inhibited at concentrations at or above the MIC (MIC=9.4 μM). As CFU counts per ml decreases at concentrations of compound above the MIC, the compound is bactericidal. The reduction in CFU/ml is faster as the concentration of test compound increases above the MIC. This indicates that the bactericidal action of the compound is primarily dependent on the concentration of the test compound.

Figure 3 illustrates a time-kill curve of C030 against S.aureus ATCC29213. Bacterial growth is inhibited at concentrations at or above the MIC (MIC=18.8 μM). As CFU counts per ml decreases at concentrations of compound above the MIC, the compound is bactericidal. The reduction in CFU/ml is faster as the concentration of test compound increases above the MIC. This indicates that the bactericidal action of the compound is primarily dependent on the concentration of the test compound.

Figure 4 illustrates a dose-response curve of LicA and one of the novel aminoalkoxy-chalcones (C130) at Plasmodium falciparum. As shown in the figure, C130 is 213 times more potent than LicA.

Figure 5 illustrates a dose-response curve of LicA and one of the novel chalcones (C019) at Leishmania Major. As shown at the figure, C019 is 100 times more potent than LicA.

Figure 6 illustrates an effect curve of C035 in Plasmodium berghei K173 infected NMRI female mice following multiple intra venous administrations. As shown at the figure, treatment with C035 causes a significant decrease in the parasitaemia.

Figure 7 illustrates an effect curve of C114, C119, C128, C130 in Plasmodium berghei K173 infected NMRI female mice following multiple oral administrations. As shown at the figure, treatments with these chalcones inhibit the development of the infection.

**DESCRIPTION OF THE INVENTION**

In an attempt to identify novel antimicrobial or antiparasitic agents, the present inventors have found that the aminoalkoxy-functional chalcones defined herein exhibit interesting biological properties combined with improved metabolic and physicochemical properties which make the compounds useful as drug substances, in particular as antiparasitic agents, bacteriostatic agents, and bactericidal agents.
It is believed that the aminoalkoxy group or groups of the aminoalkoxy-functional chalcone will be charged according to pH of the medium and the pKa of the compound. The aqueous solubility of the charged form is significantly higher than the solubility of the neutral species. As the aminoalkoxy-functional chalcones will be partially charged (i.e. soluble) at physiologically relevant pH values, e.g. in the intestine and stomach, they will dissolve in the gastric juices and be available for absorption. The bioavailability of the aminoalkoxy-functional chalcones will therefore be improved compared to the known neutral chalcones, thus making the compounds generally useful as drug candidates. Also, the present aminoalkoxy-functional chalcones display a range of pKa values which allows the selection of a chalcone derivative with optimal charged/non-charged ratio at a given pH value.

The introduction of an aliphatic amino-group and hence a positive charge (at the pH value of the target site) affects the mode of interaction with the biological target. It is anticipated that the compounds interact with the target in a different way than neutral chalcones, due to the possibility of strong electrostatic interactions (attraction as well as repulsion). This is indeed reflected in the activity of the compounds, being more potent than the previously described neutral chalcones.

Furthermore, the application of the known chalcones as drug candidates have been limited due to the extensive metabolism of the compounds resulting in short half-lives in vivo. The inventors have now found that introduction of an aminoalkoxy group in the chalcone molecule changes the metabolic properties so as to achieve improved metabolic stability.

Of particular interest, the present inventors have found that the amino-functional chalcones defined herein are far more potent against malaria and leishmania parasites than the earlier described neutral chalcone compounds, and that they exhibit excellent bacteriocidal and bacteriostatic properties, even against multi-resistant bacteria strains.

The group V is relevant with respect to the spatial orientation of the rings Ar1 and Ar2. Thus, the group V may be -CH2-CH=, -CH=CH- or -C=C-. In a currently particularly interesting embodiment V designates -CH=CH-.

In the context of the present invention the expression "chalcone derivative" has been assigned to the compounds of the above formula in that the overall structure namely Ar3-C(=O)-C-C-Ar3 resembles that of the chalcone structure. This being said, Ar1 and Ar2 are selected from aromatic rings and heteroaromatic rings. It is currently believed that particularly interesting compounds are those where at least one of Ar1 and Ar2, preferably both, are aryl, in particular phenyl. This being said, the inventors envisage that the functionality of the compounds may be substantially preserved (or even improved) when one or both of Ar1 and Ar2 are heteroaromatic rings.

In one embodiment, at least one of Ar1 and Ar2 is selected from thiazolyl, pyrrolyl, imidazolyl, pyrazolyl, pyrimidiny1, pyrazinyl, pyridazinyl, thieryl, quinolyl, isoquinolyl, and indolyl.

In another embodiment, both of Ar1 and Ar2 are phenyl and Y2 represents at least one aminoalkoxy-functional substituent, one of which being located in the 2-position of the phenyl ring, and X2 represents at least one substituent, one of which being located in the 4- or 5-position of the phenyl ring.

In yet another embodiment, both of Ar1 and Ar2 are phenyl and Y2 represents at least one aminoalkoxy-functional substituent, one of which being located in the 3-position of the phenyl ring, and X2 represents at least one substituent, one of which being located in the 5-position of the phenyl ring.

Such compounds have shown excellent bacteriostatic and bactericidal effects as well as antiparasitic effects (see the Examples).

In a further embodiment, which may combined with other embodiments herein, both of Ar1 and Ar2 are optionally substituted phenyl, and X1 represents at least one substituent, one of which being located in the 2- or 3-position of the phenyl ring, and preferably being selected from amino-C1-6-alkyl or mono- and di(C1-6-alkyl)amino-C1-6-alkyl. Such compounds have shown excellent as antiparasitic effects (see the Examples).
In a still further embodiment, which may combined with other embodiments herein, both of Ar₁ and Ar₂ are phenyl, and X¹ represents at least one substituent, one of which being located in the 4-position of the phenyl ring, and preferably being selected from hydroxy, amino-C₁₋₆-alkylamino or mono- and di(C₁₋₆-alkyl)amino-C₁₋₆-alkylamino. In one preferred embodiment, m is 1 and p is 0. In another preferred embodiment m is 0 and p is 1. In a further interesting embodiment, m and p are both 1.

In an additional interesting embodiment, one or both of X¹ and X² independently designates one optionally substituted C₁₋₁₂-alkyl group of the formula

-A-N(R⁸)Rᵐ

wherein A is a biraical -(C(Rⁿ)₂)ₙ⁻, wherein n is an integer in the range of 1-6, preferably 1-4, such as 1-3, and each Rⁿ is independently selected from hydrogen or C₁₋₆-alkyl, and R⁸ and Rᵐ may independently be selected from hydrogen, optionally substituted C₁₋₁₂-alkyl, optionally substituted C₂₋₁₂-alkenyl, optionally substituted C₄₋₁₂-alkadienyl, optionally substituted C₆₋₁₂-alkatrienyl, optionally substituted C₂₋₁₂-alkynyl, optionally substituted C₁₋₁₂-alkoxycarbonyl, optionally substituted C₁₋₁₂-alkylcarbonyl, optionally substituted aryloxy carbonyl, optionally substituted arylcarbonyl, optionally substituted heteroaryl, optionally substituted heteroaryloxy carbonyl, optionally substituted heteroaryl carbonyl, aminocarbonyl, mono- and di(C₁₋₆-alkyl)aminocarbonyl, amino-C₁₋₆-alkyl-aminocarbonyl, or mono- and di(C₁₋₆-alkyl)amino-C₁₋₆-alkyl-aminocarbonyl; or R⁸ and Rᵐ together with the nitrogen atom to which they are attached (-N(R⁸)Rᵐ) may form an optionally substituted nitrogen-containing heterocyclic ring.

In another interesting embodiment, one or both of X¹ and X² independently designates one mono- or di(C₁₋₆-alkyl)amino-C₁₋₆-alkyl-amino group of the formula

In the present context the term "nitrogen-containing heterocyclic ring" is intended to mean heterocyclic ring or ring system in which at least one nitrogen atom is present. Such a nitrogen is, with reference to the formula, carrying the substituents R\(_3\) and R\(_5\). The "nitrogen-containing heterocyclic ring" may further comprise additional heteroatoms, e.g. nitrogen (=N- or –N–), sulphur, and/or oxygen atoms. Examples of such rings are aromatic rings such as pyridine, pyridazine, pyrimidine, pyrazine, triazine, thiophene, oxazole, isoxazole, thiazole, isothiazole, pyrrole, imidazole, pyrazole, tetrazole, quinoline, benzothiazole, benzotriazole, benzodiazole, benzoxazole, triazole, isocoumarone, indole, benzopyrazole, thiazole, and oxadiazole. These most interesting examples of aromatic rings are pyridine, pyridazine, pyrimidine, pyrazine, thiophene, tetrazole, oxazole, isoxazole, thiazole, isothiazole, pyrrole, imidazole, pyrazole, quinoline, triazole, isocoumarone, indole, in particular pyridine, thiophene, imidazole, quinoline, isocoumarone, indole, and tetrazole.

Other examples of such rings are non-aromatic rings such as imidazolidine, piperazine, hexahydropyridazine, hexahydropyrimidine, diazepane, diazocane, pyrrolidine, piperidine, azepane, azocane, aziridine, azirine, azetidine, pyrrole, tropane, oxazinane (morpholine), azepine, dihydroazepine, tetrahydroazepine, and hexahydropyrazepine, oxazolane, azepane, oxazocane, thiazolane, thiazinane, thiazepane, thiazocane, oxazetane, diazetane, and thiazetane. These most interesting examples of non-aromatic rings are imidazolidine, piperazine, hexahydropyridazine, hexahydropyrimidine, diazepane, diazocane, pyrrolidine, piperidine, azepane, azocane, azetidine, tropane, oxazinane (morpholine), oxazolane, oxepane, thiazolane, thiazinane, and thiazepane, in particular imidazolidine, piperazine, hexahydropyridazine, hexahydropyrimidine, diazepane, pyrrolidine, piperidine, azepane, oxazinane (morpholine), and thiazinane.

In the present context, i.e. in connection with the term "nitrogen-containing heterocyclic ring", the term "optionally substituted" is intended to mean that the group in question may be substi-
tuted one or several times, preferably 1-5 times, in particular 1-3 times) with group(s)
selected from the same substituents as defined above for "optionally substituted aryl".

As is evident from the formulae defined herein and the definitions associated therewith, certain
compounds of the present invention are chiral. Moreover, the presence of certain unsaturated
or cyclic fragments or multiple stereogenic atoms provides for the existence of diastereomeric
forms of some of the compounds. The invention is intended to include all stereoisomers,
including optical isomers, and mixtures thereof, as well as pure, partially enriched, or, where
relevant, racemic forms. In particular, many compounds of the invention may be in the form of
E- or Z-stereoisomers, or mixtures of such isomers. The E-isomers are generally preferred.

It should furthermore be understood that the compounds defined herein include possible salts
thereof, of which pharmaceutically acceptable salts are of course especially relevant for the
therapeutic applications. Salts include acid addition salts and basic salts. Examples of acid
addition salts are hydrochloride salts, fumarate, oxalate, etc. Examples of basic salts are salts
where the (remaining) counter ion is selected from alkali metals, such as sodium and
potassium, alkaline earth metals, such as calcium salts, potassium salts, and ammonium ions
(‘N(R’)_4, where the R’s independently designate optionally substituted C_1-6-alkyl, optionally
substituted C_2-6-alkenyl, optionally substituted aryl, or optionally substituted heteroaryl).
Pharmaceutically acceptable salts are, e.g., those described in Remington’s - The Science and
0683306472, 2000, and in Encyclopedia of Pharmaceutical Technology. However, generally
preferred salt forming agents for application in the present invention are organic dicarboxylic
acids such as oxalic, fumaric, and maleic acid, and the like.

Thus, chalcones with aminoalkoxy groups can be prepared in their salt-forms thereby making
the compounds particularly useful for pharmaceutical formulations. The use of appropriate
selected salt form can be used to control the dissolution rate in vivo. Furthermore, the different
salt forms have different bulk-properties that is of importance for the manufacturing process.

Preparation of compounds
The aminoalkoxy-functional chalcones defined herein may be produced by methods known per
se for the preparation of chalcones or methods that are analogous to such methods. Examples
of excellent methods for preparing compounds of the 1,3-bis-aromatic-prop-2-enone or the
1,3-bis-aromatic-prop-2-ynone types are given in the following. Further examples of methods
for the preparation of the compound used according to the present invention are described in
WO 95/06628 and WO 93/17671 and in the references cited therein.

Compounds of the general formula I in which V is -CH=CH- can be prepared by reacting a
ketone (an acetophenone in the case where Ar^1 is phenyl)

(Y^1)_m-Ar^1(X^1)-C(=O)-CH_3

with an aldehyde (a benzaldehyde in the case where Ar^2 is phenyl)

HCO-Ar^2(X^2)-(Y^2)_p

SUBSTITUTE SHEET (RULE 26)
wherein $\text{Ar}^1$, $\text{Ar}^2$, $X^1$, $X^2$, $Y^1$, $Y^2$, $m$ and $p$ refer to the definitions given elsewhere herein.

This reaction, which is a condensation reaction, is suitably carried out under acid or base catalysed conditions. A review of such processes may be found in Nielsen, A.T., Houlihahn, W.J., *Org. React.* **16**, 1968, p 1-444. In particular the method described by Wattanasin, S. and Murphy, S., *Synthesis* (1980) 647 has been found quite successful. The reaction may suitably be carried out in protic organic solvents, such as lower alcohols (e.g. methanol, ethanol, or tert-butanol), or lower carboxylic acids (formic, glacial acetic, or propionic acid), or in aprotic organic solvents such as ethers (e.g. tetrahydrofuran, dioxane, or diethyl ether), liquid amides (e.g. dimethylformamide or hexamethylphosphoramide), dimethylsulfoxide, or hydrocarbons (e.g. toluene or benzene), or mixtures of such solvents. When carrying out the reaction under base catalysed conditions, the catalyst may be selected from sodium, lithium, potassium, barium, calcium, magnesium, aluminum, ammonium, or quaternary ammonium hydroxides, lower alkoxides (e.g. methoxides, ethoxides, tert-butoxides), carbonates, borates, oxides, hydrides, or amides of lower secondary amines (e.g. disopropyl amides or methylphenyl amides). Primary aromatic amines such as aniline, free secondary amines such as dimethyl amine, diethyl amine, piperidine, or pyrrolidine as well as basic ion exchange resins may also be used.

Acid catalysts may be selected from hydrogen chloride, hydrogen bromide, hydrogen iodide, sulfuric acid, sulfonic acids (such as paratoluensulfonic or methanesulfonic acid), lower carboxylic acids (such as formic, acetic or propionic acid), lower halogenated carboxylic acids (such as trifluoroacetic acid), Lewis acids (such as BF$_3$, POCl$_3$, PCl$_5$, or FeCl$_3$), or acid ion exchange resins.

A drawback of the base catalysed condensation is the poor yield obtained if the aromatic ring in which the ketone or the aldehyde or both is substituted with one or more hydroxy groups. This drawback can be overcome by masking the phenolic group as described by T. Hidetsugu et al. in EP 0 370 461. Deprotection is easily performed by mineral acids such as hydrochloric acid.

The reaction is typically carried out at temperatures in the range of 0-100°C, e.g. at room temperature. Reaction times are typically from 30 min to 24 hours.

The starting materials for the synthesis (acetophenone and benzaldehyde), may be obtained from commercial sources or may be synthesised according to well-known methods. The aminoalkoxy-benzaldehydes and aminoalkoxy-acetophenones can be synthesized by alkylation of the corresponding hydroxy-benzaldehydes or hydroxy-acetophenones (Figure 1). Alternatively the aminoalkoxy-chalcones can be prepared by alkylation of the corresponding hydroxy-chalcone.

Compounds of the general formula I in which V is -C=C- may be prepared by reacting an activated derivative of a carboxylic acid of the general formula

\[ (Y^1)_{m}\text{Ar}^2(X^1)\text{-COOH} \]

SUBSTITUTE SHEET (RULE 26)
with an ethyne derivative

$$\text{H-} \text{C} = \text{C}-\text{Ar}^2(\text{X}^2)-(\text{Y}^2)_p$$

wherein $\text{Ar}^1$, $\text{Ar}^2$, $\text{X}^1$, $\text{X}^2$, $\text{Y}^1$, $\text{Y}^2$, $m$, and $p$ refer to the definitions given elsewhere herein.

Reactions of this type are described by Tohda, Y., Sonogashihara, K., Haghara, N., Synthesis 1977, p 777-778. It is contemplated that the activated derivative of the carboxylic acid may be an activated ester, an anhydride or, preferably, an acid halogenide, in particular the acid chloride. The reaction is normally carried out using the catalysts described by Tohda, Y. et al. cited above, namely copper(I)iodide/triphenylphosphine-palladium dichloride. The reaction is suitably carried out in triethylamine, a mixture of triethylamine and pyridine or triethylamine and toluene under a dry inert atmosphere such as nitrogen or argon. The reaction is generally carried out at reduced temperature such as in the range from -80°C to room temperature, the reaction time typically being from 30 minutes to 6 hours.

In the above reactions, it may be preferred or necessary to protect various sensitive or reactive groups present in the starting materials to prevent said groups from interfering with the reactions. Such protection may be carried out in a well-known manner, e.g. as described in "Protective Groups in Organic Chemistry" by Wuts and Greene, Wiley-Interscience; ISBN: 0471160199; 3rd edition (May 15, 1999). For example, in the reaction between the activated acid derivative and the acetylene derivative, a hydroxy group on $\text{Ar}^1$ and/or $\text{Ar}^2$ may be protected in the form of the methoxymethyl ether, N,N-dimethylcarbamoyl ester, or allyl ether. The protecting group may be removed after the reaction in a manner known per se.

The ethyne derivative may be prepared by standard methods, e.g. as described by Nielsen, S. F. et al., Bioorg. Med. Chem. 6, pp 937-945 (1998). The carboxylic acids may likewise be prepared by standard procedures, e.g. as described in the examples.

Compounds of the general formula I in which V is $\text{-CH}_2\text{-CH}_2\text{-}$ can be prepared by ionic hydrogenation of the corresponding $\alpha,\beta$-unsaturated compound where V is $\text{-CH}=$CH$\text{-}$ as it has been described by the inventors in Nielsen, S.F. et al. Tetrahedron, 53, pp 5573-5580 (1997).

Further possible synthetic routes for the preparation of the saturated variants are described in "Advanced Organic Chemistry" by Jerry March, 3rd ed. (especially chapter 15, pages 691-700) and references cited therein. Thus, it is possible to obtain a large variety of compounds of the 1,3-bis-aromatic-propan-1-one type from the corresponding prop-2-en-1-ones.

Additional substituents defined by X² may typically be selected from the list comprising alkyl, alkenyl, and optionally substituted phenyl. X² typically designates one substituent, preferably located in the 5-position. Further preferred compounds of such embodiments include those wherein X¹ represents 0-3, such as one, amino, hydroxy, alkysulfonylamido, alkylamido, alkyl, or halo group located in the 2-, 3-, or 4-position, and those wherein X¹ represents 0-3, such as one, dialkylaminomethyl group located in the 2-, 3-, or 4-position, and those wherein X¹ represents 0-3, such as one, dialkyaminomethyl group located in the 2-, or 3-position supplemented by a haloxy or hydroxy group in the 4- or 5-position, and those wherein X¹ represents 0-3, such as one, substituent of the formula -NRº-B-N(Rº)R¹ located in the 2- or 3-position.

Preliminary results have shown that compounds wherein the $Y^2$ is the aminoalkoxy-substituent positioned in the 2 position where $\text{Ar}^1$ is phenyl, are particularly promising for the treatment of infections caused by *Plasmodium*. Those in which $X^2$ represents at least one substituent selected from $\text{C}_1-\text{C}_6$-alkyl, hydroxy, $\text{C}_1-\text{C}_6$-alkoxy, $\text{C}_1-\text{C}_6$-alkylcarbonyl, optionally substituted aryl, optionally substituted aryloxy, optionally substituted arylamin, optionally substituted heteroaryl, optionally substituted heteroarylamin, mono- and di($\text{C}_1-\text{C}_6$-alkyl)amin, $\text{C}_1-\text{C}_6$-alkylcarbonylamino, optionally substituted $\text{C}_1-\text{C}_6$-alkylthio, optionally substituted heterocyclyl, optionally substituted heterocyclyoxy, optionally substituted heterocyclylamino and halogen, in particular from $\text{C}_1-\text{C}_6$-alkyl, optionally substituted phenyl, and hydroxy, e.g. from $\text{C}_1-\text{C}_6$-alkyl and optionally substituted phenyl, appear to be particularly promising. Particular examples of efficient chalcone derivatives are those where $X^1$ represents at least one substituent, one of which being located in the 2- or 3-position of the phenyl ring, and preferably being selected from amino-$\text{C}_1-\text{C}_6$-alkyl and mono- and di($\text{C}_1-\text{C}_6$-alkyl)amin-$\text{C}_1-\text{C}_6$-alkyl, or those where $X^1$ represents at least one substituent, one of which being located in the 4-position of the phenyl ring, and preferably being selected from hydroxy, amino-$\text{C}_1-\text{C}_6$-alkylamino and mono- and di($\text{C}_1-\text{C}_6$-alkyl)amino-$\text{C}_1-\text{C}_6$-alkylamino.

One particularly suitable embodiment for such application is the one wherein $\text{Ar}^1$ and $\text{Ar}^2$ are both phenyl, $m$ is 0, $p$ is 1, and $V$ is $\text{-CH=CH}-$. Further preferred among such compounds are the ones wherein $Y^2$ is located in the 2-position, and designates a group of formula $-\text{O}(\text{CH}_2)_{2-3}^{-}$-$\text{N}(\text{R}^1)\text{R}^2$, wherein $R^1$ and $R^2$ are independently alkyl or N-containing heterocyclic ring, such as
methyl, ethyl, t-butyl, pyrrolidine, and the like. Also preferred are compounds which additionally carry a substituent as defined by $X^2$, suitably located in the 5-position, and selected from alkyl and optionally substituted aryl, such as optionally substituted phenyl. In such embodiments, substituents defined by $X^2$, if present, may typically be selected so that $X^2$ is dialkylaminomethyl located in the 2-, or 3-position, optionally supplemented by methoxy or hydroxy groups in the 4- and/or 5-positions, or selected so that $X^2$ represents 1-3 halo, alkoxy or hydroxy substituents located in the 2-, 3-, or 4-positions, such as 2, 3-dihalo-4-hydroxy, 4-halo, 2-halo-3-hydroxy, 2-butoxy, and the like, or selected so that $X^2$ represents a group of the formula \(-NR^1-B-N(R)^R\), preferably 2- or 3-(4-alkylpiperazin-1-yl), 3- or 4-((2-dialkylamino)ethyl)amino), or 2-((2-((dialkylamino)ethyl)methylamino).

Another particularly suitable embodiment such for application is the one wherein $Ar^2$ and $Ar^2$ are both phenyl, $m$ is 0, $p$ is 1, and $V$ is -CH=CH-. Among such compounds, $X^2$ may typically be a dialkylaminomethyl substituent, such as dimethylaminomethyl, suitably located in the 2-position.

Also interesting for such application are compounds wherein $Ar^1$ and $Ar^2$ are both phenyl, $m$ is 1, $p$ is 1, and $V$ is -CH=CH-. Among such compounds, preferred meanings of $Y^3$ and $Y^4$ include -O-(CH$_2$)$_2$-N(R)$^R\), wherein R$^1$ and R$^2$ are independently alkyl, such as methyl. Suitable selections of $X^1$ and $X^2$, if present, are halo, particularly 2-halo, such as 2-fluoro, and aryl, particularly optionally substituted 5-phenyl.

Other preliminary results have shown that compounds wherein the $Y^2$ is the aminoalkoxy-substituent positioned in the 2 position where $Ar^1$ is phenyl, are particularly promising for the treatment of infections caused by Leishmania spp. Those in which $X^1$ represents at least one substituent selected from C$_{1-6}$-alkyl, hydroxy, C$_{1-4}$-alkoxy, C$_{1-4}$-alkylcarbonyl, optionally substituted aryl, optionally substituted aryloxy, optionally substituted arylamino, optionally substituted heteroarylamino, mono- and di(C$_{1-4}$-alkyl)amino, C$_{1-4}$-alkylcarbonylamino, optionally substituted C$_{1-6}$-alkylthio, optionally substituted heterocyclyl, optionally substituted heterocyclyloxy, optionally substituted heterocyclaminoo and halogen, in particular from C$_{1-6}$-alkyl, optionally substituted phenyl, and hydroxy, e.g. from C$_{1-6}$-alkyl and optionally substituted phenyl, appear to be particularly promising.

Particularly suitable embodiments for such application include those wherein $Ar^1$ and $Ar^2$ are both phenyl, the sum of $m$ and $p$ is 1, and $V$ is -CH=CH-. Typically, in such compounds, $n$ is 2-6, such as 2 or 3, and the location of $Y^1$ or $Y^2$ is in the 2-, 3-, or 4-position, with the 2-position being especially preferred. Further, in such embodiments where $m$ is 1, $Y^1$ may typically be supplemented with additional groups $X^3$, suitably selected from non-charged substituents such as alkyl, alkoxy and halo, and located in the 2-, 3-, or 4-positions. In embodiments where $p$ is 1, $Y^2$ may typically be supplemented by additional substituents, $X^2$, suitably selected from non-charged, bulky groups such as alkyl and aryl and/or by substituents defined by $X^1$, suitably selected from non-charged groups such as alkyl, alkoxy and halo. Further, generally interesting embodiments are those where $X^3$ designates a dialkylaminomethyl group, suitably located in the 2-position.
Still other preliminary results indicate that compounds wherein the $Y^2$ is the aminoalkoxy-substituent positioned in the 2 position where $Ar^1$ is phenyl, are particularly promising for the treatment of infections caused by S. aureus. Those in which $X^2$ represents at least one substituent selected from $C_{1-6}$-alkyl, hydroxy, $C_{1-6}$-alkoxy, $C_{1-6}$-alkylcarbonyl, optionally substituted aryl, optionally substituted arylxy, optionally substituted arylamino, optionally substituted heteroaryl, optionally substituted heteroarylamino, mono- and di($C_{1-6}$-alkyl)amino, $C_{1-6}$-alkylcarbonylamino, optionally substituted $C_{1-6}$-alkylthio, optionally substituted heterocyclyl, optionally substituted heterocyclyoxy, optionally substituted heterocyclylamino and halogen, in particular from $C_{1-6}$-alkyl, optionally substituted phenyl, and hydroxy, e.g. from $C_{1-6}$-alkyl and optionally substituted phenyl, appear to be particularly promising.

Pharmaceutically acceptable carriers or excipients are those known by the person skilled in the art.

Thus, the present invention provides a pharmaceutical composition comprising a compound as defined herein in combination with a pharmaceutically acceptable carrier.

Pharmaceutical compositions according to the present invention may be formulated to release the active compound substantially immediately upon administration or at any substantially
predetermined time or time period after administration. The latter type of compositions are generally known as controlled release formulations.

In the present context, the term "controlled release formulation" embraces i) formulations which create a substantially constant concentration of the drug within the body over an extended period of time, ii) formulations which after a predetermined lag time create a substantially constant concentration of the drug within the body over an extended period of time, iii) formulations which sustain drug action during a predetermined time period by maintaining a relatively, constant, effective drug level in the body with concomitant minimization of undesirable side effects associated with fluctuations in the plasma level of the active drug substance (sawtooth kinetic pattern), iv) formulations which attempt to localize drug action by, e.g., spatial placement of a controlled release composition adjacent to or in the diseased tissue or organ, v) formulations which attempt to target drug action by using carriers or chemical derivatives to deliver the drug to a particular target cell type.

Controlled release formulations may also be denoted "sustained release", "prolonged release", "programmed release", "time release", "rate-controlled" and/or "targeted release" formulations.

Controlled release pharmaceutical compositions may be presented in any suitable dosage forms, especially in dosage forms intended for oral, parenteral, cutaneous nasal, rectal, vaginal and/or ocular administration. Examples include single or multiple unit tablet or capsule compositions, oil solutions, suspensions, emulsions, microcapsules, microspheres, nanoparticles, liposomes, delivery devices such as those intended for oral, parenteral, cutaneous, nasal, vaginal or ocular use.

Preparation of solid dosage forms for oral use, controlled release oral dosage forms, fluid liquid compositions, parenteral compositions, controlled release parenteral compositions, rectal compositions, nasal compositions, percutaneous and topical compositions, controlled release percutaneous and topical compositions, and compositions for administration to the eye can be performed essentially as described in the applicant's earlier International application No. WO 99/00114, page 29, line 9, to page 40, line 3. Also, and more generally, the formulation and preparation of the above-mentioned compositions are well-known to those skilled in the art of pharmaceutical formulation. Specific formulations can be found in "Remington's Pharmaceutical Sciences".

Dosages
The compound are preferably administered in an amount of about 0.1-50 mg per kg body weight per day, such as about 0.5-25 mg per kg body weight per day.

For compositions adapted for oral administration for systemic use, the dosage is normally 2 mg to 1 g per dose administered 1-4 times daily for 1 week to 12 months depending on the disease to be treated.
The dosage for oral administration for the treatment of parasitic diseases is normally 1 mg to 1 g per dose administered 1-2 times daily for 1-4 weeks, in particular the treatment of malaria is to be continued for 1-2 weeks whereas the treatment of leishmaniasis will normally be carried out for 3-4 weeks.

The dosage for oral administration for the treatment of bacterial diseases is normally 1 mg to 1 g per dose administered 1-4 times daily for 1 week to 12 months; in particular, the treatment of tuberculosis will normally be carried out for 6-12 months.

The dosage for oral administration of the composition in order to prevent diseases is normally 1 mg to 75 mg per kg body weight per day. The dosage may be administered once or twice daily for a period starting 1 week before the exposure to the disease until 4 weeks after the exposure.

For compositions adapted for rectal use for preventing diseases, a somewhat higher amount of the compound is usually preferred, i.e. from approximately 1 mg to 100 mg per kg body weight per day.

For parenteral administration, a dose of about 0.1 mg to about 50 mg per kg body weight per day is convenient. For intravenous administration a dose of about 0.1 mg to about 20 mg per kg body weight per day administered for 1 day to 3 months is convenient. For intraarticular administration a dose of about 0.1 mg to about 20 mg per kg body weight per day is usually preferable. For parenteral administration in general, a solution in an aqueous medium of 0.5-2% or more of the active ingredients may be employed.

For topical administration on the skin, a dose of about 1 mg to about 5 g administered 1-10 times daily for 1 week to 12 months is usually preferable.

In many cases, it will be preferred to administer the compound defined herein together with another antiparasitic, antimycotic or antibiotic drug, thereby reducing the risk of development of resistance against the conventional drugs, and reducing the amount of each of the drugs to be administered, thus reducing the risk of side effects caused by the conventional drugs. Important aspects of this is the use of the compound against Leishmania, where the compound is combined with another antileishmanial drug, or the antimalarial use of the compound where the compound is used together with another antimalarial drug.

Method of prediction

In a separate aspect, the present invention also provides a method of predicting whether a chemical compound has a potential inhibitory effect against a microorganism selected from Helicobacter pylori and Plasmodium falciparum, said method comprising preparing a mixture of a dihydroorotate dehydrogenase, a substrate for dihydroorotate dehydrogenase and the chemical compound, measuring the enzymatic activity of dihydroorotate dehydrogenase (A), comparing the enzymatic activity of dihydroorotate dehydrogenase (A) with the standard activity of dihydroorotate dehydrogenase (B) corresponding to the activity of a dihydroorotate dehydrogenase in a similar sample, but without the chemical compound, predicting that the
chemical compound has a potential inhibitory effect against *Helicobacter pylori* and *Plasmodium falciparum* if A is significantly lower than B.

The method can be performed as described under *DHODH Assay* in the Examples section. It should be noted that the method is not only applicable for the chalcone derivatives defined herein, but can be generally applied to predict the potential inhibitory effect of any compound. Preferably, however, the chemical compound is a chalcone derivative, e.g. a chalcone derivative as defined herein.

Determination of metabolic stability

Incubations were performed with Wistar rat liver microsomes (0.25 mg/ml) in 2% sodium bicarbonate solution. NADP (0.13 mg/ml), glucose-6-phosphate (0.63 mg/ml) and glucose-6-phosphate dehydrogenase (0.38 units/ml) were used as NADPH generation system and UDPGA (0.48 mg/ml) was added to include the phase II reaction, glucuronic acid conjugation, in the assay. After 5 minutes of pre-incubation the reaction was started by addition of the test article to give a final concentration of 20μM. Samples were incubated for 15 min at 37°C and the reactions were terminated by addition of equal volumes of acetonitrile. Blank incubations were performed at the same concentration but without addition of microsomes. Both blank and microsome-containing samples were made in replicates of three. Prior to analysis samples were centrifuged for 10 min. at 3500 rpm, HPLC system:

The fraction of compound metabolised during the 15 min of incubation was determined by comparison of blank and microsome-containing samples using a Waters Alliance 2690 separation module and Waters 996 PDA-detector(Waters. Milford, MA, USA.) Separation was performed on a XTerra MS C$_{18}$ column (150*2.1 mm I.D., 3.5 μm particle size) (Waters Milford, MA, USA) by. Initial conditions were 40% mobile phase A (acetonitrile) and 60% mobile phase B (10 mM ammonium acetate pH 9.5). During the first 20 minutes, the mobile phase was

changed via a linear gradient to 90% A and 10% B. This was followed by a 5 minutes linear gradient to initial conditions, which were maintained for 5 min. The flow rate was 0.20 ml/min and injection volume 10 μl.

**Determination of solubility**

Solubility of the compounds was determined by preparing a saturated solution of compound in 0.3 M phosphate buffer (pH 7.4 ± 0.3) in a brown glass tube. The suspensions were rotated slowly for 24 hours. Aliquots were centrifuged for 10 minutes at 14,000 rpm and supernatants were diluted in 40% (v/v) acetonitrile in water prior to HPLC analysis. Concentrations of analytes were quantified against a standard curve and used as term of solubility. The HPLC-UV method used for the assessment of solubility is the same as used in the *in vitro* metabolism assay.

**Pharmacokinetic Studies**

Evaluation of the pharmacokinetic properties of the compounds was done using female NMRI mice (weighing app. 30 g). Test articles were administrated intravenously and orally as a cassette dose formulations containing three compounds or as individual compounds. Samples of serum were taken at defined timepoints.

Standards and QC-samples in plasma were prepared and the serum concentrations of the test compounds quantified by HPLC-MS. Prior to analysis, proteins were precipitated by deluding the samples (1:1) (v/v) with 100% acetonitrile followed by centrifugation at 14,000 rpm in 10 min. The supernatant was used for the analysis.

**HPLC-MS system:**

A Waters Alliance HPLC-system (Milford, MA, USA) was coupled to a Quatro Micro triple quadrupol mass spectrometer (Micromass, Manchester, UK) operating in positive (ESI) mode. Separation was performed on a X Terra MS C18 column (150*2.1 mm I.D., 3,5 μm particle size) (Waters Milford, MA, USA).

Mobile phase A: 0.1% (v/v) formic acid or 10 mM ammonium acetate pH-adjusted to 9.5 in MilliQ-water, mobile phase B: 100% methanol. The gradient was as follows: 0 min = 70%A – 30% B, 0-10 min. a linear gradient to 10% A and 90 % B this was maintained till 11 min, 11-13 linear gradient to 70% A and 30% B this was maintained till 18 min. The flow rate was 0.20 ml/min, injection volume 10 μl.

**Biological testing**

**General methods**

**In vitro microbiological testing**

*MIC determination in broth microdilution assay*
Compounds were screened for activity against a panel of 10 different non-fastidious bacteria growing aerobically (Staphylococcus aureus ATCC29213; Staphylococcus aureus ATCC33591; Staphylococcus intermedius #2357 (clinical isolate from the Copenhagen area); Enterococcus faecalis ATCC29212; Enterococcus faecium #17501 (vancomycin-resistant clinical isolate); Streptococcus pneumoniae #998 (clinical isolate); Streptococcus pyogenes #14813 (clinical isolate); Streptococcus agalactiae #19855 (clinical isolate); Eschericia coli ATCC25922 and Eschericia coli ESS). The screening assay was done in 200 μl MH-broth cultures in microtirte plates. For compounds exhibiting activity in the initial screen MIC was determined in a microdilution assay using MH-broth as described by NCLLS (National Committee for Clinical Laboratory Standards. Methods for Dilution Antimicrobial Susceptibility Tests for Bacteria That Grow Aerobically; Approved Standard – Fifth Edition. M7-A5 NCCLS 2000) modified to include uninoculated dilution series of test compounds to facilitate MIC determination if the test compound should precipitate. MIC was determined as the lowest concentration of test compound able to inhibit visible growth of bacteria. MICs for ATCC type strains fell within the limits posted by the NCCLS (National Committee for Clinical Laboratory Standards. Performance Standards for Antimicrobial Susceptibility Testing; Eleventh Informational Supplement. M100-S11 NCCLS 2001) when tested against vancomycin, tetracycline, gentamycin.

**MIC and MBC determination in broth macrodilution assay**

MIC and MBC of test compounds were determined in a broth macrodilution assay using 2 ml MH-broth cultures and an inoculum of approximately 5x10E5 CFU/ml as described by Amsterdam (Amsterdam, D. Susceptibility testing of antimicrobials in liquid media. In V.Lorian (ed.): Antibiotics in Laboratory Medicin 4. edition. Williams & Wilkins 1996). MIC was determined as the minimal concentration of test compound able to inhibit visible growth of bacteria. Samples from cultures inhibited by test compound were plated onto unselective blood agar plates. MBC was determined as the minimal concentration of test compound able to decrease colony count on these plates below 0.1% compared to the original inoculum.

**Killing Curve determination**

For the determination of the killing curve of a test compound a dilution series of test compound was made and inoculated with approximately 5x10E5 CFU/ml as described for the MIC macrodilution assay above. At the timepoints indicated 100 μl samples was withdrawn from the test tubes, serially diluted and spotted in duplicate on unselective agar plates to determine CFU. Test compounds with bactericidal activity is capable of decreasing surviving colony counts (CFU/ml) when incubated with bacteria. Bactericidal activity may be either primarily dependent on concentration of test compound or on incubation time with test compound. An example of a bactericidal compound (C023), which is primarily dependent on the concentration of the test compound is shown in Figure 2. An example of a bactericidal compound (C030) which is primarily dependent on the incubation time with the compound is shown in Figure 3.
MIC determination against Helicobacter pylori

Six strains of Helicobacter pylori were used in an agar dilution assay according to the standards of NCCLS (National Committee for Clinical Laboratory Standards. Methods for Dilution Antimicrobial Susceptibility Tests for Bacteria That Grow Aerobically; Approved Standard – Fifth Edition. M7-A5 NCCLS 2000). MH-agar plates supplemented with 5% horse blood and containing a dilution series of the test compound were inoculated in duplicate with 10 μl spots of a 2 MCF suspension of the different strains of H. pylori. This inoculum corresponds to approximately 10^6 CFU/spot. Plates were then incubated in a microaerophilic atmosphere at 35°C for 72 hours. The MIC endpoint was determined as the lowest concentration of test compound able to completely inhibit or most significantly reduce growth compared to growth control plates not containing test compounds.

Activity determination against anaerobic bacteria

Screening for activity against anaerobic bacteria was done against two isolates of Bacteroides fragilis, an isolate of Clostridium difficile and an isolate of Clostridium perfringens in an agar dilution assay as described by NCCLS (National Committee for Clinical Laboratory Standards. Methods for Antimicrobial Susceptibility Testing of Anaerobic Bacteria; Approved Standard – Fifth Edition. M11-A5 NCCLS 2000) with the exception that Mueller-Hinton agar was used in place of supplemented Brucella broth. Plates containing test compound at a single concentration (either 100 or 150 μM) were prepared in duplicate along with appropriate control plates. Activity was present if growth in the presence of test substance was absent or most significantly reduced compared to growth control plates not containing test compound.

Leishmania promastigote assay

A WHO reference vaccine strain of L.major originally isolated from a patient in Iran were cultured in Medium 199 with Hanks’ Salts containing 0.02 mg/ml gentamycin, 25 mM HEPES, 4 mM L-glutamine, and 10% heat inactivated fetal calf serum (FCS). Incubation was carried out at 27°C. Promastigotes were harvested at day 3 of culture and used for the assay of inhibition of parasite growth.

The effect of test compounds on promastigotes was assessed by a method modified from Pearson et al. Briefly, promastigotes (0.8x10^5/well) were incubated in 200 μl duplicate cultures either with a dilution series of test compound or medium alone in 96 wells flat bottom microtiter plates. After 2h of incubation, 1.5 μCi of 3H-thymidine was added to each well and further incubated for 18 hours. The cultures were then harvested on Unifilter-GF/C microtiter filter plates (Packard Instruments), washed extensively and counted in a TopCount-NXT microplate scintillation counter (Packard Instruments).

Plasmodium falciparum assay

Plasmodium falciparum 3D7 was maintained in culture by a modification of the method originally described by Trager and Jensen. In brief, the parasites were grown in suspensions of human blood group 0 erythrocytes (RBC) maintained in RPMI1640 medium supplemented with 4.5 g/l Albumax II (Invitrogen), 10 mM hypoxantine, 1.4 mM L-glutamine and 0.05 mg/ml
gentamicin. Cultures were incubated at 37°C in atmosphere of 92.5% nitrogen, 5.5% carbon dioxide, and 2% oxygen. To obtain synchronized cultures of parasites erythrocytes infected with late trophozoite and schizont stages were separated from ring stages and uninfected RBC by magnet-activated cell sorting (MACS; Miltenyl Biotec) (Staalsoe, T., H.A. Gjha, D. Dodoo, T.G. Theander, and L. Hvid. 1999. Detection of antibodies to variant antigens on Plasmodium falciparum-infected erythrocytes by flow cytometry. Cytometry 35:329-336). Because of their high content of paramagnetic haemoglobin, erythrocytes infected with late developmental stages of malaria parasites are specifically retained within the column. The column was washed with PBS supplemented with 2% foetal calf serum and then the column was removed from the magnet and the retained late developmental stages of parasites were eluted and cultured for an additional 18 hours. At this time the culture is highly synchronous containing more than 90% ring stages.

These synchronized cultures of ring stage parasites were used to assay for antimalarial parasites. Briefly, cultures of ring stage parasites were adjusted to 1% parasitemia by addition of uninfected RBC. Then, these were incubated in 125 µl duplicate cultures containing 2.5x10^7 RBC/well with either a dilution series of test compound or with medium alone. Plates were then incubated at 37°C for 24 hours when cultures were labelled by the addition 1.1 µCl 3H-phenylalanine and incubated overnight. Then, the cultures were harvested on Unifilter-GF/C microfilter plates (Packard Instruments) and washed extensively with water followed by a wash with 10% H_2O_2 to bleach hemoglobin. Filter plates were counted in a TopCount-NXT microplate scintillation counter (Packard Instruments).

**DHODH Assay**

100 µl chalcone or 0.1 M Tris-HCl pH 8.0 is added to a well in a 96-wells microtiter plate. Then 50 µl enzyme dilution is added. The microtiter plate is placed in the Powerwave,340 and the enzymatic reactions starts when adding 100 µl assay mixture. The reaction are measured every 20 sec. for 10 min. The samples with chalcones are compared with the samples with 0.1 M Tris-HCl pH 8.0 and the percent inhibition is calculated.

Enzyme dilution: The solution of recombinant purified enzyme is dissolved in 0.1 M Tris-HCl pH 8 to give an initial velocity of 0.04 - 0.05 ΔA/min.

2,6-dichlorophenolindophenol (DCIP)-stock solution: 40 mg DCIP and 10 ml 99 % Ethanol are mixed for 10 min at RT. Then 100 µl 1.0 M Tris-HCl pH 8 and milliQ H_2O are added to a final volume of 100 ml. The A_{600} of the DCIP-stock solution are measured in a microtiter plate on the Powerwave,340 (Bio-Tek Instruments,Inc.)

Dihydroorotate dehydrogenase (DHODH)-stock solution: 25 mM dihydroorotate stock-solution is prepared by first dissolving in the same amount of mol NaOH and then milliQ H_2O is added to the final volume.

Assay mix (10 ml solution): 600 µl of DHODH-stock solution and X ml (depending on the A_{600} value of stock-solution) DCIP to a final A_{600} = 2.5 are mixed. Then 0.1 M Tris-HCl pH 8.0 are added to a final volume of 10 ml.

Preparation of compound solution: A 10 mM stock-solution of compound (e.g. a chalcone derivative) is made in dimethylsulfoxid (DMSO). The compound is then diluted in 0.1 M Tris-HCl pH 8 to the test concentrations. The final DMSO concentration in the sample is 10%
Biological Results

Licochalcone A (LicA) and 4′-methoxy chalcone (4′MC) described in WO 93/17671 are used as reference compounds in the following discussion.

Activity against non-fastidious bacteria

Licochalcone A exhibits moderate bactericidal activity against common pathogenic Gram-positive non-fastidious bacteria including Staphylococcus aureus, Enterococcus faecalis, Enterococcus faecium, Streptococcus pneumoniae, Streptococcus pyogenes, and Streptococcus agalactiae. Licochalcone A maintains its activity also against antibiotic resistant bacteria, e.g. Staphylococcus aureus ATCC33591 (resistant to methicillin) and Enterococcus faecium #17051 (resistant to vancomycin). In contrast, Licochalcone A has only modest or no activity against the prototype pathogenic Gram-negative bacterium, Eschericia coli. 4′MC as a representative of non-hydroxyl chalcones exhibits no antibacterial effect at all.

In comparison with Licochalcone A, aminoalkoxy-functional chalcones retain the activity of Licochalcone A against pathogenic Gram-positive bacteria including antibiotic-resistant strains (cf. Table 1). The aminoalkoxy-functional chalcones exhibit increased potency against Gram-positive pathogens (e.g. C004, C015, C023, C030, C037, C042). In contrast to Licochalcone A, aminoalkoxy-functional chalcones exhibit activity against Eschericia coli. Thus, several aminoalkoxy-functional chalcones (e.g. C074, C075, C103) exhibit high activity against E.coli ATCC25922 and against the generally more susceptible ESS strain of E.coli (cf. Table 1). This indicates the potential use of aminoalkoxy-functional chalcones in the treatment of infections associated with Gram-negative bacteria.

In the treatment of severe infections in immunocompromised patients bactericidal action of an antibiotic is a necessity. As exemplified in Figures 2 and 3, aminoalkoxy chalcones retain the bactericidal action of Licochalcone A. For aminoalkoxy chalcones the bactericidal action is predominantly dependent on the concentration of the compound (e.g. C023 and C030; cf. Figure 2 and 3). This knowledge is helpful when designing dosing regimens for in vivo efficacy trials.

Activity against Helicobacter pylori

Colonisation of the gastric mucosa with *Helicobacter pylori* is an important pathogenic determinant for the development of gastritis and peptic ulcer. Aminoalkoxychalones exhibit activity against *Helicobacter pylori*. Several aminoalkoxychalones (e.g. C004, C010, C014, C022, C030, C088, C094) exhibit MICs in the range between 12 μM and 25 μM when tested against a panel of six strains *Helicobacter pylori*, that includes strains resistant to metronidazole. Metronidazol is an antibiotic commonly included in treatment regimens designed to eradicate *Helicobacter* colonization for the treatment of peptic ulcer. The activity of aminoalkoxychalones against both metronidazole-resistant and sensitive *Helicobacter pylori* clearly indicates the potential use of these compounds in the treatment of *Helicobacter* infections.

**Activity against anaerobic bacteria**

Aminoalkoxychalones have been assayed in a single concentration of compound (100 μM) for activity against a panel of anaerobic bacteria containing common human pathogenic bacteria (*Bacteroides fragilis, Clostridium perfringens, Clostridium difficile*). Several aminoalkoxychalones (e.g. C015, C025, C026, C028 and C042, C074, C079) exhibit activity against all microorganisms within the test panel. This clearly indicates the potential use of aminoalkoxychalones in treatment of infection caused by anaerobic bacteria.

**Activity against protozoa**

**Activity against Plasmodium falciparum**

*Plasmodium falciparum* is a protozoan parasite transmitted by the mosquito *Anopheles*, and causing malignant or severe malaria in humans. Licochalcone A exhibits activity against *Plasmodium falciparum in vitro* and protects mice from infection with *P. yoelii and P. berghei* (Chen et al., 1994). Aminoalkoxychalones exhibit activity in vitro against Plasmodium falciparum and several aminochalones exhibit improved potency compared to Licochalcone A (cf. Table 2 and Figure 4). Furthermore, the compounds are potent against chloroquine resistant parasites as shown in Table 3. The results clearly indicate the potential use of aminoalkoxychalones in the treatment of malaria.

Activity against *Leishmania major*

*Leishmania major* is a protozoan parasite transmitted by the sandfly Phlebotomus, and causing cutaneous leishmaniasis or kala-azar in humans. Licochalcone A exhibits activity against *Leishmania* parasites and has shown efficacy in experimental animal models of cutaneous and visceral *Leishmania* infection (Chen et al., 1994). Aminoalkoxychalones exhibit activity *in vitro* against *Leishmania major* with significantly improved potency compared to Licochalcone A and 4'MC (cf. Table 4). The results clearly indicate the potential use of aminoalkoxychalones in the treatment of *Leishmania* infection.

Inhibition of DHODH

Metabolism
The usefulness of chalcones as drug candidates have been limited by the metabolism of the compounds resulting in short half-lives in vivo (LicA: 100% turn-over in vitro and $t_{1/2} = 10$ min in vivo).

The introduction of an aminoalkoxy group in the chalcone changes the metabolic properties; this is clear from Table 6 where the metabolic turn-over of a number of aminoalkoxy-chalcones are compared to LicA. The aminoalkoxy-chalcones prepared are expected to show low or no metabolism in vivo as the metabolic turn-over are between 0-10% (compared to 100% turn-over for LicA). Consequently the half-life of a aminoalkoxy-chalcone will be longer, reducing the dose needed for treatment.

Solubility
The aqueous solubility of the neutral chalcones described in WO 93/17671 is very low. A representative chalcone 4'-methoxy-chalcone has a solubility of <0.05 mg/ml. A few chalcones have a higher solubility due to (metabolically unstable) hydroxyl groups in the molecule. LicA has a solubility of approximately 0.01 mg/ml.
The aminoalkoxy-chalcones described in this application are superior having solubility numbers in sub-mg/ml. Representative examples are shown in table 7.

The high aqueous solubility means that dissolution and hence absorption will be no problem. This will inevitably cause a dramatic reduction of the dose needed making the aminoalkoxy-chalcones very useful as drug candidates.

Bioavailability
The bioavailability of the aminoalkoxy chalcones are markedly higher than seen for LicA. The compound C043 has a bioavailability of 42% in mice compared with <6 % for LicA.

Bioavailability
The bioavailability of the aminoalkoxy chalcones in mice is in generally very high (e.g. 42% for C043). As the mouse is a very fast metabolizer of the amino chalcones, compared to rat and human (e.g. C130 mice: 77%; rat: 6%; human: in general lower than rat), the bioavailability in rat and man is expected to be even higher due to limited first pass metabolism.

SUBSTITUTE SHEET (RULE 26)
In vivo results
A number of amino-chalcones have significant effect in the *in vivo* models. As illustrated in figures 6 and 7, the compounds cause a significant reduction of parasitaemia in plasmodium infected mice, showing the potential of the compounds as drug candidates.

Conclusion
The use of chalcones as drug candidates for the treatment of parasitic or bacterial infections has been limited by the low *in vivo* potency (50mg/kg for LicA) of the compounds and a narrow spectrum of activity.

Several factors contribute to the low in vivo potency: Fast metabolism resulting in short half-lives in vivo; low/no solubility in the intestine and consequently low/no absorption; and medium potency of the compounds against parasites and no activity against bacteria (except for LicA).

The aminoalkoxy-chalcones in this application are expected to fulfill the criteria for a drug candidate. The metabolism is slow, the solubility is high and the compounds are potent against parasites as well as (resistant) Gram positive and Gram negative bacteria.
