

US009352171B2

(12) **United States Patent**
Gertner

(10) **Patent No.:** **US 9,352,171 B2**

(45) **Date of Patent:** ***May 31, 2016**

(54) **NERVE TREATMENT SYSTEM**

(71) Applicant: **Kona Medical, Inc.**, Palo Alto, CA (US)

(72) Inventor: **Michael Gertner**, Menlo Park, CA (US)

(73) Assignee: **Kona Medical, Inc.**, Bellevue, WA (US)

(*) Notice: Subject to any disclaimer, the term of this patent is extended or adjusted under 35 U.S.C. 154(b) by 446 days.

This patent is subject to a terminal disclaimer.

(21) Appl. No.: **13/751,133**

(22) Filed: **Jan. 27, 2013**

(65) **Prior Publication Data**

US 2013/0138018 A1 May 30, 2013

Related U.S. Application Data

(63) Continuation of application No. 13/019,273, filed on Feb. 1, 2011, now Pat. No. 8,374,674, which is a continuation of application No. 12/902,135, filed on Oct. 11, 2010, now abandoned, application No.

(57) **ABSTRACT**

A method of treatment includes delivering an agent into a patient, and providing energy inside the patient so that the energy can interact with the agent to treat a nerve. A system for treatment includes a source of agent for delivery into a patient, and an energy source for providing energy inside the patient so that the energy can interact with the agent to treat a nerve.

PRIORITY DATA

This applications is a continuation of U.S. patent application Ser. No. 13/019,273, filed Feb. 1, 2011, pending, which is a continuation of U.S. patent application Ser. No. 12/902,135, filed Oct. 11, 2010, which claims priority to and the benefit of U.S. Provisional patent application 61/377,908 filed Aug. 27, 2010, and U.S. Provisional patent application 61/347,375 filed May 21, 2010, and is a continuation-in-part of U.S. patent application Ser. No. 12/725,450 filed Mar. 16, 2010, now pending, which is a continuation-in-part of U.S. patent application Ser. No. 12/685,655, filed on Jan. 11, 2010, now pending, which claims priority to and the benefit of U.S. Provisional Patent Application No. 61/256,983 filed Oct. 31, 2009, U.S. Provisional Patent Application No. 61/250,857 filed Oct. 12, 2009, U.S. Provisional Patent Application No. 61/261,741 filed Nov. 16, 2009, and U.S. Provisional Patent Application No. 61/291,359 filed Dec. 30, 2009.

U.S. patent application Ser. No. 12/725,450 also claims priority to, and the benefit of U.S. Provisional Patent Application No. 61/303,307 filed Feb. 10, 2010, U.S. Provisional Patent Application No. 61/256,983 filed Oct. 31, 2009, U.S. Provisional Patent Application No. 61/250,857 filed Oct. 12, 2009, U.S. Provisional Patent Application No. 61/261,741 filed Nov. 16, 2009, and U.S. Provisional Patent Application No. 61/291,359 filed Dec. 30, 2009.

The disclosures of all of the above referenced applications are expressly incorporated by reference herein.

The following patent applications are also expressly incorporated by reference herein.

U.S. patent application Ser. Nos. 11/583,569, 12/762,938, 11/583,656, 12/247,969, 10/633,726, 09/721,526, 10/780,405, 09/747,310, 12/202,195, 11/619,996, 09/696,076, 11/016,701, 12/887,178, 12/390,975, 12/887,178, 12/887,211, 12/887,232

It should be noted that the subject matters of the above applications and any other applications referenced herein are expressly incorporated into this application as if they are expressly recited in this application. Thus, in the instance where the references are not specifically labeled as "incorporated by reference" in this application, they are in fact deemed described in this application.

BACKGROUND

Energy delivery from a distance involves transmission of energy waves to affect a target at a distance. It allows for more efficient delivery of energy to targets and a greater cost efficiency and technologic flexibility on the generating side. For example, cellular phones receive targets from towers close to the user and the towers communicate with one another over a long range; this way, the cell phones can be low powered and communicate over a relatively small range yet the network can quickly communicate across the world. Similarly, electricity distribution from large generation stations to the users is more efficient than the users themselves looking for solutions.

In terms of treating a patient, delivering energy over a distance affords great advantages as far as targeting accuracy, technologic flexibility, and importantly, limited invasiveness into the patient. In a simple form, laparoscopic surgery has replaced much of the previous open surgical procedures and lead to creation of new procedures and devices as well as a more efficient procedural flow for disease treatment. Laparoscopic tools deliver the surgeon's energy to the tissues of the

patient from a distance and results in improved imaging of the region being treated as well as the ability for many surgeons to visualize the region at the same time.

Perhaps the most important aspect is the fact that patients have much less pain, fewer complications, and the overall costs of the procedures are lower. Visualization is improved as is the ability to perform tasks relative to the visualization.

Continued advances in computing, miniaturization and economization of energy delivery technologies, and improved imaging will lead to still greater opportunities to apply energy from a distance into the patient and treat disease.

SUMMARY

In some embodiments, a method of treatment includes delivering an agent into a patient, and providing energy inside the patient so that the energy can interact with the agent to treat a nerve.

In some embodiments, the energy comprises electromagnetic energy.

In some embodiments, the energy is in a form of light.

In some embodiments, the agent comprises a molecule, and the energy activates the molecule to cause the molecule to release a substance.

In some embodiments, the substance comprises a free radical for damaging the nerve.

In some embodiments, the agent comprises a sensitizer molecule.

In some embodiments, the sensitizer molecule comprises a photosensitizer molecule.

In some embodiments, the agent is sensitive to light at 763 nm wavelength.

In some embodiments, the energy is in a form of light, and the act of providing the energy comprises inserting a catheter into a vessel, and using a light source on the catheter to provide the light.

In some embodiments, the nerve surrounds at least a part of the vessel, and the light delivered inside the vessel travels through a wall of the vessel to reach the nerve.

In some embodiments, the energy is in a form of light, and the act of providing the light comprises inserting a fiber optic into a vessel, and using the fiber optic to transmit the light to a region within the vessel.

In some embodiments, the nerve surrounds at least a part of the vessel, and the light in the vessel travels through a wall of the vessel to reach the nerve.

In some embodiments, the nerve comprises a renal nerve.

In some embodiments, the nerve surrounds a vessel, and is next to a kidney.

In some embodiments, the energy ranges from approximately 50 to 300 Joules.

In some embodiments, the energy does not heat the nerve.

In some embodiments, the energy does not cause temperature inside the body to rise above 37.8 degrees Celsius.

In some embodiments, the energy is delivered from outside the patient to inside the patient.

In some embodiments, the act of providing the energy comprises placing a probe percutaneously in a vicinity of a blood vessel that is surrounded by the nerve.

In some embodiments, the energy comprises a focused energy.

In some embodiments, the energy is in a form of visible light.

In some embodiments, the energy is in a form of non-visible light.

In some embodiments, the energy is in a form of infrared light.

In some embodiments, the nerve is an autonomic nerve, and the energy is provided to treat the autonomic nerve.

In some embodiments, the energy is provided to treat hypertension.

In some embodiments, a system for treatment includes a source of agent for delivery into a patient, and an energy source for providing energy inside the patient so that the energy can interact with the agent to treat a nerve.

In some embodiments, the energy comprises electromagnetic energy.

In some embodiments, the energy is in a form of light.

In some embodiments, the agent comprises a molecule, and the energy source is configured to provide the energy for activating the molecule to cause the molecule to release a substance.

In some embodiments, the substance comprises a free radical for damaging the nerve.

In some embodiments, the agent comprises a sensitizer molecule.

In some embodiments, the sensitizer molecule comprises a photosensitizer molecule.

In some embodiments, the agent is sensitive to light at 763 nm wavelength.

In some embodiments, the system further includes a catheter that carries the energy source, wherein the catheter is sized for insertion into a vessel.

In some embodiments, the nerve surrounds at least a part of the vessel, and the energy source is configured to deliver the energy in a form of light inside the vessel, so that the light can travel through a wall of the vessel to reach the nerve.

In some embodiments, the energy is in a form of light, and the act of providing the light comprises inserting a fiber optic into a vessel, and using the fiber optic to transmit the light to a region within the vessel.

In some embodiments, the nerve surrounds at least a part of the vessel, and the light in the vessel travels through a wall of the vessel to reach the nerve.

In some embodiments, the energy source is configured for providing energy inside the patient so that the energy can interact with the agent to treat a renal nerve.

In some embodiments, the energy source is configured for providing energy inside the patient so that the energy can interact with the agent to treat a nerve that surrounds a vessel, and that is next to a kidney.

In some embodiments, the energy ranges from approximately 50 to 300 Joules.

In some embodiments, the energy does not heat the nerve.

In some embodiments, the energy does not cause temperature inside the body to rise above 37.8 degrees Celsius.

In some embodiments, the energy source is configured for use outside the patient, and is configured to deliver the energy from outside the patient to inside the patient.

In some embodiments, the energy source is coupled to a probe configured to be inserted into the patient percutaneously to reach a vicinity of a blood vessel that is surrounded by the nerve.

In some embodiments, the energy comprises a focused energy.

In some embodiments, the energy source is configured to provide visible light.

In some embodiments, the energy source is configured to provide non-visible light.

In some embodiments, the energy source is configured to provide infrared light.

In some embodiments, the nerve is an autonomic nerve, and the energy source is configured to provide the energy to treat the autonomic nerve.

In some embodiments, the energy source is configured to provide the energy to treat hypertension.

In some embodiments, a system for treatment includes a source of photosensitizer compound for delivering the photosensitizer compound inside a patient, a catheter with a distal end for placement inside a blood vessel of the patient, and a light projecting element carried by the catheter, the light projecting element configured for applying light from inside the blood vessel to interact with the photosensitizer compound to thereby treat a nerve outside the blood vessel, wherein the light projecting element is configured to create a gradient of light intensity from outside the vessel to inside of the vessel, the light intensity being greater outside the vessel than inside the vessel.

In some embodiments, the photosensitizer compound comprises a molecule, and the light projecting element is configured to provide the light for activating the molecule to cause the molecule to release a substance.

In some embodiments, the substance comprises a free radical for damaging the nerve.

In some embodiments, the compound comprises a sensitizer molecule.

In some embodiments, the photosensitizer compound is sensitive to light at 763 nm wavelength.

In some embodiments, the light projecting element is configured to provide visible light.

In some embodiments, the light projecting element is configured to provide non-visible light.

In some embodiments, the light projecting element is configured to provide infrared light.

In some embodiments, the nerve is an autonomic nerve, and the light projecting element is configured to provide the light to treat the autonomic nerve.

In some embodiments, the light projecting element is configured to provide the light to treat hypertension.

DESCRIPTION OF FIGURES

FIGS. 1a-b depict the focusing of energy sources on nerves of the autonomic nervous system.

FIG. 1c depicts an imaging system to help direct the energy sources.

FIG. 2 depicts targeting and/or therapeutic ultrasound delivered through the stomach to the autonomic nervous system posterior to the stomach.

FIG. 3a depicts focusing of energy waves on the renal nerves.

FIG. 3b depicts a coordinate reference frame for the treatment.

FIG. 3C depicts targeting catheters placed in any of the renal vessels.

FIG. 3D depicts an image detection system of a blood vessel with a temporary fiducial placed inside.

FIG. 3E depicts a therapy paradigm for the treatment and assessment of hypertension.

FIG. 4a depicts the application of energy to the autonomic nervous system surrounding the carotid arteries.

FIG. 4B depicts the application of energy to through the vessels of the renal hilum.

FIGS. 5a-b depicts the application of focused energy to the autonomic nervous system of the eye.

FIG. 6 depicts the application of constricting lesions to the kidney deep inside the calyces of the kidney.

FIG. 7a depicts a patient in an imaging system receiving treatment with focused energy waves.

FIG. 7b depicts visualization of a kidney being treated.

5

FIG. 7c depicts a close up view of the renal nerve region of the kidney being treated.

FIG. 7d depicts an algorithmic method to treat the autonomic nervous system using MRI and energy transducers.

FIG. 7e depicts a geometric model obtained from cross-sectional images of the area of the aorta and kidneys.

FIG. 7f depicts a close up image of the region of treatment.

FIG. 7g depicts the results of measurements from a series of cross sectional image reconstructions.

FIG. 7h depicts the results of measurements from a series of cross-sectional images from a patient in a more optimized position.

FIG. 7i depicts an algorithmic methodology to apply treatment to the hilum of the kidney and apply energy to the renal blood vessels.

FIG. 8a depicts a percutaneous approach to treating the autonomic nervous system surrounding the kidneys.

FIG. 8b depicts an intravascular approach to treating or targeting the autonomic nervous system.

FIG. 8c depicts a percutaneous approach to the renal hila using a CT scan and a probe to reach the renal blood vessels.

FIGS. 9a-c depicts the application of energy from inside the aorta to regions outside the aorta to treat the autonomic nervous system.

FIG. 10 depicts steps to treat a disease using HIFU while monitoring progress of the treatment as well as motion.

FIG. 11a depicts treatment of brain pathology using cross sectional imaging.

FIG. 11b depicts an image on a viewer showing therapy of the region of the brain being treated.

FIG. 11c depicts another view of a brain lesion as might be seen on an imaging device which assists in the treatment of the lesion.

FIG. 12 depicts treatment of the renal nerve region using a laparoscopic approach.

FIG. 13 depicts a methodology for destroying a region of tissue using imaging markers to monitor treatment progress.

FIG. 14 depicts the partial treatment of portions of a nerve bundle using converging imaging and therapy wave.

FIG. 15a-b depicts the application of focused energy to the vertebral column to treat various spinal pathologies including therapy of the spinal or intravertebral nerves.

FIG. 15c illustrates applying energy to a spinal region.

FIG. 16A depicts the types of lesions which are created around the renal arteries to affect a response.

FIG. 16B depicts a simulation of ultrasound around a blood vessel I support of FIG. 16A.

FIG. 16C depicts data from ultrasound energy applied to the renal blood vessels and the resultant change in norepinephrine levels.

FIG. 17A depicts the application of multiple transducers to treat regions of the autonomic nervous system at the renal hilum.

FIGS. 17B-C depict methods for using imaging to direct treatment of a specific region surrounding an artery as well as display the predicted lesion morphology.

FIG. 17D depicts a method for localizing HIFU transducers relative to Doppler ultrasound signals.

FIG. 17E depicts an arrangement of transducers relative to a target.

FIG. 17F depicts ablation zones in a multi-focal region in cross-section.

FIG. 18 depicts the application of energy internally within the kidney to affect specific functional changes at the regional level within the kidney.

6

FIG. 19A depicts the direction of energy wave propagation to treat regions of the autonomic nervous system around the region of the kidney hilum.

FIG. 19B depicts a schematic of a B mode ultrasound from a direction determined through experimentation to provide access to the renal hilum with HIFU.

FIG. 20 depicts the application of ultrasound waves through the wall of the aorta to apply a therapy to the autonomic nervous system.

FIG. 21A depicts application of focused energy to the ciliary muscles and processes of the anterior region of the eye.

FIG. 21B depicts the application of focused non-ablative energy to the back of the eye to enhance drug or gene delivery or another therapy such as ionizing radiation.

FIG. 22 depicts the application of focused energy to nerves surrounding the knee joint to affect nerve function in the joint.

FIGS. 23A-B depicts the application of energy to the fallopian tube to sterilize a patient.

FIG. 24 depicts an algorithm to assess the effect of the neural modulation procedure on the autonomic nervous system. After a procedure is performed on the renal nerves, assessment of the autonomic response is performed by, for example, simulating the autonomic nervous system in one or more places.

FIG. 25 depicts an optimized position of a device to apply therapy to internal nerves.

FIG. 26A depicts positioning of a patient to obtain parameters for system design.

FIG. 26B depicts a device design based on the information learned from feasibility studies.

FIG. 27 depicts a clinical paradigm for treating the renal nerves of the autonomic nervous system based on feasibility studies.

FIG. 28 A-C depicts a treatment positioning system for a patient incorporating a focused ultrasound system.

FIG. 29 A-D depicts results of studies applying focused energy to nerves surrounding arteries and of ultrasound studies to visualize the blood vessels around which the nerves travel.

FIG. 29E depicts the results of design processes in which the angle, length, and surface area from CT scans is quantified.

FIGS. 30A-I depicts results of simulations to apply focused ultrasound to the region of a renal artery with a prototype device design based on simulations.

DETAILED DESCRIPTION

Hypertension is a disease of extreme national and international importance. There are 80 million patients in the US alone who have hypertension and over 200 million in developed countries worldwide. In the United States, there are 60 million patients who have uncontrolled hypertension, meaning that they are either non-compliant or cannot take the medications because of the side effect profile. Up to 10 million people might have completely resistant hypertension in which they do not reach target levels no matter what the medication regimen. The morbidities associated with uncontrolled hypertension are profound, including stroke, heart attack, kidney failure, peripheral arterial disease, etc. A convenient and straightforward minimally invasive procedure to treat hypertension would be a very welcome advance in the treatment of this disease.

Congestive Heart Failure ("CHF") is a condition which occurs when the heart becomes damaged and blood flow is reduced to the organs of the body. If blood flow decreases sufficiently, kidney function becomes altered, which results

in fluid retention, abnormal hormone secretions and increased constriction of blood vessels. These results increase the workload of the heart and further decrease the capacity of the heart to pump blood through the kidneys and circulatory system.

It is believed that progressively decreasing perfusion of the kidneys is a principal non-cardiac cause perpetuating the downward spiral of CHF. For example, as the heart struggles to pump blood, the cardiac output is maintained or decreased and the kidneys conserve fluid and electrolytes to maintain the stroke volume of the heart. The resulting increase in pressure further overloads the cardiac muscle such that the cardiac muscle has to work harder to pump against a higher pressure. The already damaged cardiac muscle is then further stressed and damaged by the increased pressure. Moreover, the fluid overload and associated clinical symptoms resulting from these physiologic changes result in additional hospital admissions, poor quality of life, and additional costs to the health care system. In addition to exacerbating heart failure, kidney failure can lead to a downward spiral and further worsening kidney function. For example, in the forward flow heart failure described above, (systolic heart failure) the kidney becomes ischemic. In backward heart failure (diastolic heart failure), the kidneys become congested vis-à-vis renal vein hypertension. Therefore, the kidney can contribute to its own worsening failure.

The functions of the kidneys can be summarized under three broad categories: filtering blood and excreting waste products generated by the body's metabolism; regulating salt, water, electrolyte and acid-base balance; and secreting hormones to maintain vital organ blood flow. Without properly functioning kidneys, a patient will suffer water retention, reduced urine flow and an accumulation of waste toxins in the blood and body. These conditions result from reduced renal function or renal failure (kidney failure) and are believed to increase the workload of the heart. In a CHF patient, renal failure will cause the heart to further deteriorate as fluids are retained and blood toxins accumulate due to the poorly functioning kidneys. The resulting hypertension also has dramatic influence on the progression of cerebrovascular disease and stroke.

The autonomic nervous system is a network of nerves which affect almost every organ and physiologic system to a variable degree. Generally, the system is composed of sympathetic and parasympathetic nerves. For example, the sympathetic nerves to the kidney traverse the sympathetic chain along the spine and synapse within the ganglia of the chain or within the celiac ganglia, then proceeding to innervate the kidney via post-ganglionic fibers inside the "renal nerves." Within the renal nerves, which travel along the renal hila (artery and to some extent the vein), are the post-ganglionic sympathetic nerves and the afferent nerves from the kidney. The afferent nerves from the kidney travel within the dorsal root (if they are pain fibers) and into the anterior root if they are sensory fibers, then into the spinal cord and ultimately to specialized regions of the brain. The afferent nerves, baroreceptors and chemoreceptors, deliver information from the kidneys back to the sympathetic nervous system via the brain; their ablation or inhibition is at least partially responsible for the improvement seen in blood pressure after renal nerve ablation, or denervation, or partial disruption. It has also been suggested and partially proven experimentally that the baroreceptor response at the level of the carotid sinus is mediated by the renal artery afferent nerves such that loss of the renal artery afferent nerve response blunts the response of the carotid baroreceptors to changes in arterial blood pressure

(American J. Physiology and Renal Physiology 279:F491-F501, 2000, incorporated by reference herein).

It has been established in animal models that the heart failure condition results in abnormally high sympathetic activation of the kidneys. An increase in renal sympathetic nerve activity leads to decreased removal of water and sodium from the body, as well as increased renin secretion which stimulates aldosterone secretion from the adrenal gland. Increased renin secretion can lead to an increase in angiotensin II levels which leads to vasoconstriction of blood vessels supplying the kidneys as well as systemic vasoconstriction, all of which lead to a decrease in renal blood flow and hypertension. Reduction in sympathetic renal nerve activity, e.g., via de-innervation, may reverse these processes and in fact has been shown to in the clinic. Similarly, in obese patients, the sympathetic drive is intrinsically very high and is felt to be one of the causes of hypertension in obese patients.

Recent clinical work has shown that de-innervation of the renal sympathetic chain and other nerves which enter the kidney through the hilum can lead to profound systemic effects in patients (rats, dogs, pig, sheep, humans) with hypertension, heart failure, and other organ system diseases. Such treatment can lead to long term reduction in the need for blood pressure medications and improvements in blood pressure (O'Brien Lancet 2009 373; 9681 incorporated by reference). The devices used in this trial were highly localized radiofrequency (RF) ablation to ablate the renal artery adventitia with the presumption that the nerves surrounding the renal artery are being inhibited in the heating zone as well. The procedure is performed in essentially a blind fashion in that the exact location of the nerve plexus is not known prior to, during, or after the procedure. In addition, the wall of the renal artery is invariably damaged by the RF probe and patients whose vessels have a great deal of atherosclerosis cannot be treated safely. In addition, depending on the distance of the nerves from the vessel wall, the energy may not consistently lead to ablation or interruption. Finally, the use of internal catheters may not allow for treatment inside the kidney or inside the aorta if more selective. In many cases, it is required to create a spiral along the length and inside the blood vessel to avoid circumferential damage to the vessel.

Cross-sectional imaging can be utilized to visualize the internal anatomy of patients via radiation (CT) or magnetic fields (MRI). Ultrasound can also be utilized to obtain cross-sections of specific regions but only at high frequencies; therefore, ultrasound is typically limited to imaging superficial body regions. CT and MRI are often more amenable to cross sectional imaging because the radiation penetrates well into tissues. In addition, the scale of the body regions is maintained such that the anatomy within the coordinate references remains intact relative to one another; that is, distances between structures can be measured.

With ultrasound, scaling can be more difficult because of unequal penetration as the waves propagate deeper through the tissue. CT scans and MRIs and even ultrasound devices can be utilized to create three dimensional representations and reconstructed cross-sectional images of patients; anatomy can be placed in a coordinate reference frame using a three dimensional representation. Once in the reference frame, energy devices (transducers) can be placed in position and energy emitting devices directed such that specific regions of the body are targeted. Once knowledge of the transducer position is known relative to the position of the target in the patient body, energy can be delivered to the target.

Ultrasound is a cyclically generated sound pressure wave with a frequency greater than the upper limit of human hear-

ing . . . 20 kilohertz (kHz). In medicine, ultrasound is widely utilized because of its ability to penetrate tissues. Reflection of the sound waves reveals a signature of the underlying tissues and as such, ultrasound can be used extensively for diagnostics and potentially therapeutics as well in the medical field. As a therapy, ultrasound has the ability to both penetrate tissues and can be focused to create ablation zones. Because of its simultaneous ability to image, ultrasound can be utilized for precise targeting of lesions inside the body. Ultrasound intensity is measured by the power per cm^2 (for example, W/cm^2 at the therapeutic target region). Generally, high intensity refers to intensities over $0.1\text{-}5\text{ kW}/\text{cm}^2$. Low intensity ultrasound encompasses the range up to $0.01\text{-}0.10\text{ kW}/\text{cm}^2$ from about 1 or 10 Watts per cm^2 .

Ultrasound can be utilized for its forward propagating waves and resulting reflected waves or where energy deposition in the tissue and either heating or slight disruption of the tissues is desired. For example, rather than relying on reflections for imaging, lower frequency ultrasonic beams (e.g. $<1\text{ MHz}$) can be focused at a depth within tissue, creating a heating zone or a defined region of cavitation in which microbubbles are created, cell membranes are opened to admit bioactive molecules, or damage is otherwise created in the tissue. These features of ultrasound generally utilize frequencies in the $0.25\text{ Megahertz (MHz)}$ to 10 MHz range depending on the depth required for effect. Focusing is, or may be, required so that the surface of the tissue is not excessively injured or heated by single beams. In other words, many single beams can be propagated through the tissue at different angles to decrease the energy deposition along any single path yet allow the beams to converge at a focal spot deep within the tissue. In addition, reflected beams from multiple angles may be utilized in order to create a three dimensional representation of the region to be treated in a coordinate space.

It is important when planning an ultrasound therapy that sharp, discontinuous interfaces be avoided. For example, bowel, lung, bone which contain air and/or bone interfaces constitute sharp boundaries with soft tissues. These interfaces make the planning and therapy more difficult. If however, the interfaces can be avoided, then treatment can be greatly simplified versus what has to done for the brain (e.g. MR-guided HIFU) where complex modeling is required to overcome the very high attenuation of the cranium. Data provided below reveals a discovery through extensive experimentation as to how to achieve this treatment simplicity.

Time of flight measurements with ultrasound can be used to range find, or find distances between objects in tissues. Such measurements can be utilized to place objects such as vessels into three dimensional coordinate reference frames so that energy can be utilized to target the tissues. SONAR is the acronym for sound navigation and ranging and is a method of acoustic localization. Sound waves are transmitted through a medium and the time for the sound to reflect back to the transmitter is indicative of the position of the object of interest. Doppler signals are generated by a moving object. The change in the forward and reflected wave results in a velocity for the object.

The concept of speckle tracking is one in which the reflections of specific tissues is defined and tracked over time (IEEE Transactions on Ultrasonics, Ferroelectrics, AND Frequency Control, Vol. 57, no. 4, April 2010, herein incorporated by reference). With defined points in space, a three dimensional coordinate reference can be created through which energy can be applied to specific and well-defined regions. To track a speckle, an ultrasound image is obtained from a tissue. Light and dark spots are defined in the image, these light and dark spots representing inhomogeneities in the

tissues. The inhomogeneities are relatively constant, being essentially properties of the tissue. With relatively constant markers in the tissue, tracking can be accomplished using real time imaging of the markers. With more than one plane of ultrasound, the markers can be related in three dimensions relative to the ultrasound transducer and a therapeutic energy delivered to a defined position within the three dimensional field.

At the time one or more of these imaging modalities is utilized to determine the position of the target in three dimensions, then a therapy can be both planned and applied to a specific region within the three dimensional volume.

Lithotripsy was introduced in the early part of the 1980's. Lithotripsy utilizes shockwaves to treat stones in the kidney. The Dornier lithotripsy system was the first system produced for this purpose. The lithotripsy system sends ultrasonic waves through the patient's body to the kidney to selectively heat and vibrate the kidney stones; that is, selectively over the adjacent tissue. At the present time, lithotripsy systems do not utilize direct targeting and imaging of the kidney stone region. A tremendous advance in the technology would be to image the stone region and target the specific region in which the stone resides so as to minimize damage to surrounding structures such as the kidney. In the case of a kidney stone, the kidney is in fact the speckle, allowing for three dimensional targeting and tracking off its image with subsequent application of ultrasound waves to break up the stone. In the embodiments which follow below, many of the techniques and imaging results described can be applied to clinical lithotripsy.

Histotripsy is a term given to a technique in which tissue is essentially vaporized using cavitation rather than heating (transcutaneous non-thermal mechanical tissue fractionation). These mini explosions do not require high temperature and can occur in less than a second. The generated pressure wave is in the range of megapascals (MPa) and even up to or exceeding 100 MPa . To treat small regions of tissue very quickly, this technique can be very effective. The border of the viable and non-viable tissue is typically very sharp and the mechanism of action has been shown to be cellular disruption.

In one embodiment, ultrasound is focused on the region of the renal arteries and/or veins from outside the patient; the ultrasound is delivered from multiple angles to the target, thereby overcoming many of the deficiencies in previous methods and devices put forward to ablate renal sympathetic nerves which surround the renal arteries.

Specifically, one embodiment allows for precise visualization of the ablation zone so that the operator can be confident that the correct region is ablated and that the incorrect region is not ablated. Because some embodiments do not require a puncture in the skin, they are considerably less invasive, which is more palatable and safer from the patient standpoint. Moreover, unusual anatomies and atherosclerotic vessels can be treated using external energy triangulated on the renal arteries to affect the sympathetic and afferent nerves to and from the kidney respectively.

With reference to FIG. 1A, the human renal anatomy includes the kidneys **100** which are supplied with oxygenated blood by the renal arteries **200** and are connected to the heart via the abdominal aorta **300**. Deoxygenated blood flows from the kidneys to the heart via the renal veins (not shown) and thence the inferior vena cava (not shown). The renal anatomy includes the cortex, the medulla, and the hilum. Blood is delivered to the cortex where it filters through the glomeruli and is then delivered to the medulla where it is further filtered through a series of reabsorption and filtration steps in the loops of henle and individual nephrons; the ultrafiltrate then

11

percolates to the ureteral collecting system and is delivered to the ureters and bladder for ultimate excretion.

The hila is the region where the major vessels (renal artery and renal vein) and nerves **150** (efferent sympathetic, afferent sensory, and parasympathetic nerves) travel to and from the kidneys. The renal nerves **150** contain post-ganglionic efferent nerves which supply sympathetic innervation to the kidneys. Afferent sensory nerves travel from the kidney to the central nervous system and are postganglionic afferent nerves with nerve bodies in the central nervous system. These nerves deliver sensory information to the central nervous system and are thought to regulate much of the sympathetic outflow from the central nervous system to all organs including the skin, heart, kidneys, brain, etc.

In one method, energy is delivered from outside a patient, through the skin, and to the renal afferent and/or renal efferent nerves. Microwave, light, vibratory (e.g. acoustic), ionizing radiation might be utilized in some or many of the embodiments.

Energy transducers **510** (FIG. 1A) deliver energy transcutaneously to the region of the sympathetic ganglia **520** or the post-ganglionic renal nerves **150** or the nerves leading to the adrenal gland **400**. The energy is generated from outside the patient, from multiple directions, and through the skin to the region of the renal nerves **624** which surround the renal artery **620** or the sympathetic ganglion **622** which house the nerves. The energy can be focused or non-focused but in one preferred embodiment, the energy is focused with high intensity focused ultrasound (HIFU) or low intensity focused ultrasound.

Focusing with low intensity focused ultrasound (LIFU) may also occur intentionally as a component of the HIFU (penumbra regions) or unintentionally. The mechanism of nerve inhibition is variable depending on the "low" or "high" of focused ultrasound. Low energy might include energies levels of 25 W/cm²-200 W/cm². Higher intensity includes energy levels from 200 W/cm² to 1 MW/cm². Focusing occurs by delivering energy from at least two different angles through the skin to meet at a focal point where the highest energy intensity and density occurs. At this spot, a therapy is delivered and the therapy can be sub-threshold nerve interruption (partial ablation), ablation (complete interruption) of the nerves, controlled interruption of the nerve conduction apparatus, partial ablation, or targeted drug delivery. The region can be heated to a temperature of less than 60 degrees Celsius for non-ablative therapy or can be heated greater than 60 degrees Celsius for heat based destruction (ablation). To ablate the nerves, even temperatures in the 40 degree Celsius range can be used and if generated for a time period greater than several minutes, will result in ablation. For temperatures at about 50 degrees Celsius, the time might be under one minute. Heating aside, a vibratory effect for a much shorter period of time at temperatures below 60 degrees Celsius can result in partial or complete paralysis of destruction of the nerves. If the temperature is increased beyond 50-60 degrees Celsius, the time required for heating is decreased considerably to affect the nerve via the sole mechanism of heating. In some embodiments, an imaging modality is included as well in the system. The imaging modality can be ultrasound based, MRI based, or CT (X-Ray) based. The imaging modality can be utilized to target the region of ablation and determined the distances to the target.

The delivered energy can be ionizing or non-ionizing energy in some embodiments. Forms of non-ionizing energy can include electromagnetic energy such as a magnetic field, light, an electric field, radiofrequency energy, and light based energy. Forms of ionizing energy include x-ray, proton beam,

12

gamma rays, electron beams, and alpha rays. In some embodiments, the energy modalities are combined. For example, heat ablation of the nerves is performed and then ionizing radiation is delivered to the region to prevent re-growth of the nerves.

Alternatively, ionizing radiation is applied first as an ablation modality and then heat applied afterward in the case of re-growth of the tissue as re-radiation may not be possible (complement or multimodality energy utilization). Ionizing radiation may prevent or inhibit the re-growth of the nervous tissue around the vessel if there is indeed re-growth of the nervous tissue. Therefore, another method of treating the nerves is to first heat the nerves and then apply ionizing radiation to prevent re-growth.

Other techniques such as photodynamic therapy including a photosensitizer and light source to activate the photosensitizer can be utilized as a manner to combine modalities. Most of these photosensitizing agents are also sensitive to ultrasound energy yielding the same photoreactive species as if it were activated by light. A photoreactive or photosensitive agent can be introduced into the target area prior to the apparatus being introduced into the blood vessel; for example, through an intravenous injection, a subcutaneous injection, etc. However, it will be understood that if desired, the apparatus can optionally include a lumen for delivering a photoreactive agent into the target area. The resulting embodiments are likely to be particularly beneficial where uptake of the photoreactive agent into the target tissues is relatively rapid, so that the apparatus does not need to remain in the blood vessel for an extended period of time while the photoreactive agent is distributed into and absorbed by the target tissue.

Light source arrays can include light sources that provide more than one wavelength or waveband of light. Linear light source arrays are particularly useful to treat elongate portions of tissue. Light source arrays can also include reflective elements to enhance the transmission of light in a preferred direction. For example, devices can beneficially include expandable members such as inflatable balloons to occlude blood flow (which can interfere with the transmission of light from the light source to the intended target tissue) and to enable the apparatus to be centered in a blood vessel. Another preferred embodiment contemplates a transcutaneous PDT method where the photosensitizing agent delivery system comprises a liposome delivery system consisting essentially of the photosensitizing agent.

Yet another embodiment of the present invention is drawn to a method for transcutaneous ultrasonic therapy of a target lesion in a mammalian subject utilizing a sensitizer agent. In this embodiment, the biochemical compound is activated by ultrasound through the following method:

1) administering to the subject a therapeutically effective amount of an ultrasonic sensitizing agent or a ultrasonic sensitizing agent delivery system or a prodrug, where the ultrasonic sensitizing agent or ultrasonic sensitizing agent delivery system or prodrug selectively binds to the thick or thin neointimas, nerve cells, nerve sheaths, nerve nuclei, arterial plaques, vascular smooth muscle cells and/or the abnormal extracellular matrix of the site to be treated. Nerve components can also be targeted, for example, the nerve sheath, myelin, S-100 protein. This step is followed by irradiating at least a portion of the subject with ultrasonic energy at a frequency that activates the ultrasonic sensitizing agent or if a prodrug, by a prodrug product thereof, where the ultrasonic energy is provided by an ultrasonic energy emitting source. This embodiment further provides, optionally, that the ultrasonic therapy drug is cleared from non-target tissues of the subject prior to irradiation.

A preferred embodiment of this invention contemplates a method for transcutaneous ultrasonic therapy of a target tissue, where the target tissue is close to a blood vessel.

Other preferred embodiments of this invention contemplate that the ultrasonic energy emitting source is external to the patient's intact skin layer or is inserted underneath the patient's intact skin layer, but is external to the blood vessel to be treated. An additional preferred embodiment of this invention provides that the ultrasonic sensitizing agent is conjugated to a ligand and more preferably, where the ligand is selected from the group consisting of: a target lesion specific antibody; a target lesion specific peptide and a target lesion specific polymer. Other preferred embodiments of the present invention contemplate that the ultrasonic sensitizing agent is selected from the group consisting of: indocyanine green (ICG); methylene blue; toluidine blue; aminolevulinic acid (ALA); chlorin compounds; phthalocyanines; porphyrins; purpurins; texaphyrins; and any other agent that absorbs light in a range of 500 nm-1100 nm. A preferred embodiment of this invention contemplates that the photosensitizing agent is indocyanine green (ICG).

Other embodiments of the present invention are drawn to the presently disclosed methods of transcutaneous PDT, where the light source is positioned in proximity to the target tissue of the subject and is selected from the group consisting of: an LED light source; an electroluminescent light source; an incandescent light source; a cold cathode fluorescent light source; organic polymer light source; and inorganic light source. A preferred embodiment includes the use of an LED light source.

Yet other embodiments of the presently disclosed methods are drawn to use of light of a wavelength that is from about 500 nm to about 1100 nm, preferably greater than about 650 nm and more preferably greater than about 700 nm. A preferable embodiment of the present method is drawn to the use of light that results in a single photon absorption mode by the photosensitizing agent.

Additional embodiments of the present invention include compositions of photosensitizer targeted delivery system comprising: a photosensitizing agent and a ligand that binds a receptor on the target tissue with specificity. Preferably, the photosensitizing agent of the targeted delivery system is conjugated to the ligand that binds a receptor on the target (nerve or adventitial wall of blood vessel) with specificity. More preferably, the ligand comprises an antibody that binds to a receptor. Most preferably, the receptor is an antigen on thick or thin neointimas, intimas, adventitia of arteries, arterial plaques, vascular smooth muscle cells and/or the extracellular matrix of the site to be treated.

A further preferred embodiment of this invention contemplates that the photosensitizing agent is selected from the group consisting of: indocyanine green (ICG); methylene blue; toluidine blue; aminolevulinic acid (ALA); chlorin compounds; phthalocyanines; porphyrins; purpurins; texaphyrins; and any other agent that absorbs light in a range of 500 nm-1100 nm.

Other photosensitizers of the present invention are known in the art, including, photofrin, RTM, synthetic diporphyrins and dichlorins, phthalocyanines with or without metal substituents, chloroaluminum phthalocyanine with or without varying substituents, chloroaluminum sulfonated phthalocyanine, O-substituted tetraphenyl porphyrins, 3,1-meso tetrakis (o-propionamido phenyl) porphyrin, verdins, purpurins, tin and zinc derivatives of octaethylpurpurin, etiopurpurin, hydporphyrins, bacteriochlorins of the tetra(hydroxyphenyl) porphyrin series, chlorins, chlorin e6, mono-l-aspartyl derivative of chlorin e6, di-l-aspartyl derivative of chlorin e6,

tin(IV) chlorin e6, meta-tetrahydroxyphenylchlorin, benzoporphyrin derivatives, benzoporphyrin monoacid derivatives, tetracyanoethylene adducts of benzoporphyrin, dimethyl acetylenedicarboxylate adducts of benzoporphyrin, Diels-Adler adducts, monoacid ring "a" derivative of benzoporphyrin, sulfonated aluminum PC, sulfonated AlPc, disulfonated, tetrasulfonated derivative, sulfonated aluminum naphthalocyanines, naphthalocyanines with or without metal substituents and with or without varying substituents, zinc naphthalocyanine, anthracenediones, anthrapyrazoles, aminoanthraquinone, phenoxazine dyes, phenothiazine derivatives, chalcogenapyrylium dyes, cationic seleno and tellurapyrylium derivatives, ring-substituted cationic PC, pheophorbide derivative, pheophorbide alpha and ether or ester derivatives, pyropheophorbides and ether or ester derivatives, naturally occurring porphyrins, hematoporphyrin, hematoporphyrin derivatives, hematoporphyrin esters or ethers, protoporphyrin, ALA-induced protoporphyrin IX, endogenous metabolic precursors, 5-aminolevulinic acid benzonaphthoporphyrazines, cationic iminium salts, tetracyclines, lutetium texaphyrin, tin-etio-purpurin, porphycenes, benzophenothiazinium, pentaphyrins, texaphyrins and hexaphyrins, 5-amino levulinic acid, hypericin, pseudo-hypericin, hypocrellin, terthiophenes, azaporphyrins, azachlorins, rose bengal, phloxine B, erythrosine, iodinated or brominated derivatives of fluorescein, merocyanines, nile blue derivatives, pheophytin and chlorophyll derivatives, bacteriochlorin and bacteriochlorophyll derivatives, porphocyanines, benzochlorins and oxobenzochlorins, sapphyrins, oxasapphyrins, cercosporins and related fungal metabolites and combinations thereof.

Several photosensitizers known in the art are FDA approved and commercially available. In a preferred embodiment, the photosensitizer is a benzoporphyrin derivative ("BPD"), such as BPD-MA, also commercially known as BPD Verteporfin or "BPD" (available from QLT). U.S. Pat. No. 4,883,790 describes BPD compositions. BPD is a second-generation compound, which lacks the prolonged cutaneous phototoxicity of Photofrin® (Levy (1994) *Semin Oncol* 21: 4-10). BPD has been thoroughly characterized (Richter et al., (1987) *JNCI* 79:1327-1331), (Aveline et al. (1994) *Photochem Photobiol* 59:328-35), and it has been found to be a highly potent photosensitizer for PDT.

In a preferred embodiment, the photosensitizer is tin ethyl etiopurpurin, commercially known as purlytin (available from Miravant).

In some embodiments, external neuromodulation is performed in which low energy ultrasound is applied to the nerve region to modulate the nerves. For example, it has been shown in the past that low intensity (e.g. non-thermal) ultrasound can affect nerves at powers which range from 30-500 mW/Cm² whereas HIFU (thermal modulation), by definition generates heat at a focus, requires power levels exceeding 1000 W/Cm². The actual power flux to the region to be ablated is dependent on the environment including surrounding blood flow and other structures. With low intensity ultrasound, the energy does not have to be so strictly focused to the target because it's a non-ablative energy; that is, the vibration or mechanical pressure may be the effector energy and the target may have a different threshold for effect depending on the tissue. However, even low energy ultrasound may require focusing if excessive heat to the skin is a worry or if there are other susceptible structures in the path and only a pinpoint region of therapy is desired. Nonetheless, transducers 500 in FIG. 1a provide the ability to apply a range of different energy and power levels as well as modeling capability to target different regions and predict the response.

15

In FIG. 1a, and in one embodiment, a renal artery **640** is detected with the assistance of imaging devices **600** such as Doppler ultrasound, infrared imaging, thermal imaging, B-mode ultrasound, MRI, or a CT scan. With an image of the region to be treated, measurements in multiple directions on a series of slices can be performed so as to create a three-dimensional representation of the area of interest. By detecting the position of the renal arteries from more than one angle via Doppler triangulation (for example) or another triangulation technique, a three dimensional positional map can be created and the renal artery can be mapped into a coordinate reference frame. In this respect, given that the renal nerves surround the renal blood vessels in the hilum, locating the direction and lengths of the blood vessels in three dimensional coordinate reference is the predominant component of the procedure to target these sympathetic nerves. Within the three dimensional reference frame, a pattern of energy can be applied to the vicinity of the renal artery from a device well outside the vicinity (and outside of the patient altogether) based on knowledge of the coordinate reference frame.

For example, once the renal artery is placed in the coordinate reference frame with the origin of the energy delivery device, an algorithm is utilized to localize the delivery of focused ultrasound to heat or apply mechanical energy to the adventitia and surrounding regions of the artery which contain sympathetic nerves to the kidney and afferent nerves from the kidney, thereby decreasing the sympathetic stimulus to the kidney and decreasing its afferent signaling back to the autonomic nervous system; affecting these targets will modulate the propensity toward hypertension which would otherwise occur. The ultrasonic energy delivery can be modeled mathematically by predicting the acoustic wave dissipation using the distances and measurements taken with the imaging modalities of the tissues and path lengths.

In one embodiment of an algorithm, the Doppler signal from the artery is identified from at least two different directions and the direction of the artery is reconstructed in three dimensional space. With two points in space, a line is created and with knowledge of the thickness of the vessel, a tube, or cylinder, can be created to represent the blood vessel as a virtual model. The tube is represented in three dimensional space over time and its coordinates are known relative to the therapeutic transducers outside of the skin of the patient. Therapeutic energy can be applied from more than one direction as well and can focus on the cylinder (blood anterior vessel wall, central axis, or posterior wall).

Focused energy (e.g. ultrasound) can be applied to the center of the vessel (within the flow), on the posterior wall of the vessel, in between (e.g. when there is a back to back artery and vein next to one another) the artery vessel and a venous vessel, etc.

Imaging **600** of the sympathetic nerves or the sympathetic region (the target) is also utilized so as to assess the direction and orientation of the transducers relative to the target **620**; the target is an internal fiducial, which in one embodiment is the kidney **610** and associated renal artery **620** because they can be localized via their blood flow, a model then produced around it, and then they both can be used as a target for the energy. Continuous feedback of the position of the transducers **500**, **510** relative to the target **620** is provided by the imaging system in which the coordinate space of the imaging system. The imaging may be a cross-sectional imaging technology such as CT or MRI or it may be an ultrasound imaging technology which yields faster real time imaging. In some embodiments, the imaging may be a combination of technologies such as the fusion of MRI/CT and ultrasound. The imaging system can detect the position of the target in real

16

time at frequencies ranging from 1 Hz to thousands and tens of thousands of images per second.

In the example of fusion, cross-sectional imaging (e.g. MRI/CT) is utilized to place the body of the patient in a three dimensional coordinate frame and then ultrasound is linked to the three dimensional reference frame and utilized to track the patient's body in real time under the ultrasound linked to the cross-sectional imaging. The lack of resolution provided by the ultrasound is made up for by the cross-sectional imaging since only a few consistent anatomic landmarks are required for an ultrasound image to be linked to the MRI image. As the body moves under the ultrasound, the progressively new ultrasound images are linked to the MRI images and therefore MRI "movement" can be seen at a frequency not otherwise available to an MRI series.

In one embodiment, ultrasound is the energy used to inhibit nerve conduction in the sympathetic nerves. In one embodiment, focused ultrasound (HIFU) from outside the body through the skin is the energy used to inhibit sympathetic stimulation of the kidney by delivering waves from a position external to the body of a patient and focusing the waves on the sympathetic nerves on the inside of the patient and which surround the renal artery of the patient.

As is depicted in FIG. 3a-b, transducers **900** can emit ultrasound energy from a position outside the patient to the region of the renal sympathetic nerves at the renal pedicle **200**. As shown in FIG. 1a, an image of the renal artery **620** using an ultrasound, MRI, or CT scan can be utilized to determine the position of the kidney **610** and the renal artery **620** target. Doppler ultrasound can be used to determine the location and direction of a Doppler signal from an artery and place the vessel into a three dimensional reference frame **950**, thereby enabling the arteries **200** and hence the sympathetic nerves **220** (FIG. 3a) around the artery to be much more visible so as to process the images and then utilize focused external energy to pinpoint the location and therapy of the sympathetic nerves. In this embodiment, ultrasound is likely the most appropriate imaging modality.

FIG. 1a also depicts the delivery of focused energy to the sympathetic nerve trunks and ganglia **622** which run along the vertebral column and aorta **300**; the renal artery efferent nerves travel in these trunks and synapse to ganglia within the trunks. In another embodiment, ablation of the dorsal and ventral roots at the level of the ganglia or dorsal root nerves at T9-T11 (through which the afferent renal nerves travel) would produce the same or similar effect to ablation at the level of the renal arteries.

In another embodiment, FIG. 1b illustrates the application of ionizing energy to the region of the sympathetic nerves on the renal arteries **620** and/or renal veins. In general, energy levels of greater than 20 Gy (Gray) are required for linear accelerators or low energy x-ray machines to ablate nervous tissue using ionizing energy; however, lower energy is required to stun, inhibit nervous tissue, or prevent re-growth of nervous tissue; in some embodiment, ionizing energy levels as low as 2-5 Gy or 5-10 Gy or 10-15 Gy are delivered in a single or fractionated doses.

Combinations of ionizing energy and other forms of energy can be utilized in this embodiment as well so as to prevent re-growth of the nervous tissue. For example, a combination of heat and/or vibration and/or cavitation and/or ionizing radiation might be utilized to prevent re-growth of nervous tissue after the partial or full ablation of the nervous tissue surrounding the renal artery.

FIG. 2 illustrates the renal anatomy and surrounding anatomy with greater detail in that organs such as the stomach **700** are shown in its anatomic position overlying the abdomi-

nal aorta **705** and renal arteries **715**. In this embodiment, energy is delivered through the stomach to reach an area behind the stomach. In this embodiment, the stomach is utilized as a conduit to access the celiac ganglion **710**, a region which would otherwise be difficult to reach. The aorta **705** is shown underneath the stomach and the celiac ganglion **710** is depicted surrounding the superior mesenteric artery and aorta. A transorally placed tube **720** is placed through the esophagus and into the stomach. The tube overlies the celiac ganglion when placed in the stomach and can therefore be used to deliver sympatholytic devices or pharmaceuticals which inhibit or stimulate the autonomic celiac ganglia behind the stomach; these therapies would be delivered via transabdominal ultrasound or fluoroscopic guidance (for imaging) through the stomach. Similar therapies can be delivered to the inferior mesenteric ganglion, renal nerves, or sympathetic nerves traveling along the aorta through the stomach or other portion of the gastrointestinal tract. The energy delivery transducers **730, 731** are depicted external to the patient and can be utilized to augment the therapy being delivered through the stomach to the celiac ganglion. Alternatively, the energy delivery transducers can be utilized for imaging the region of therapy.

In one embodiment, energy is applied to the region of the celiac ganglion from a region outside the patient. In this embodiment, fluid is placed into the gastrointestinal system, such as for example, in the stomach or small intestine. Ultrasound can then be transmitted through the gastrointestinal organs to the ganglia of interest behind the stomach.

Temporary neurostimulators can also be placed through the tube, such as, for example, in an ICU setting where temporary blockage of the autonomic ganglia may be required. Temporary neurostimulators can be used to over pace the celiac ganglion nerve fibers and inhibit their function as a nerve synapse. Inhibition of the celiac ganglion may achieve a similar function as ablation or modulation of the sympathetic nerves around the renal arteries. That is, the decrease in the sympathetic activity to the kidneys (now obtained with a more proximal inhibition) leads to the lowering of blood pressure in the patient by decreasing the degree of sympathetic outflow from the sympathetic nerve terminals. In the celiac ganglia, the blood pressure lowering effect is more profound given that the celiac ganglia are pre-ganglionic and have more nerve fibers to a greater number of regions than each renal nerve. The effect is also likely more permanent than the effect on the post-ganglionic nerve fibers.

FIG. **3a** illustrates the renal anatomy more specifically in that the renal nerves **220** extending longitudinally along the renal artery **200**, are located generally within, or just outside the adventitia, of the outer portion of the artery. Arteries are typically composed of three layers: the first is the intimal, the second is the media, and the third is the adventitia. The outer layer, the adventitia, is a fibrous tissue which contains blood vessels and nerves. The renal nerves are generally postganglionic sympathetic nerves although there are some ganglia which exist distal to the takeoff from the aorta such that some of the nerve fibers along the renal artery are in fact pre-ganglionic. By the time the fibers reach the kidney, the majority of the fibers are post-ganglionic. The afferent nerves on the other hand leave the kidney and are post-ganglionic up to the level of the brain. These fibers do no re-grow as quickly as the efferent fibers, if at all.

Energy generators **900** deliver energy to the renal nerves accompanying the renal artery, depositing energy from multiple directions to target inhibition of the renal nerve complex. The energy generators can deliver ultrasound energy, ionizing radiation, light (photon) therapy, or microwave energy to the

region. The energy can be non-focused in the case where a pharmaceutical agent is targeted to the region to be ablated or modulated. Preferably, however, the energy is focused, being applied from multiple angles from outside the body of the patient to reach the region of interest (e.g. sympathetic nerves surrounding blood vessels). The energy transducers **900** are placed in an X-Y-Z coordinate reference frame **950**, as are the organs such as the kidneys. The x-y-z coordinate frame is a real space coordinate frame. For example, real space means that the coordinate reference is identifiable in the physical world; like a GPS (global positioning system), with the physical coordinates, a physical object can be located. Once in the x-y-z coordinate reference frame, cross-sectional imaging using MRI, CT scan, and/or ultrasound is utilized to couple the internal anatomy to the energy transducers. These same transducers may be utilized for the determination of the reference point as well as the therapy. The transducers **900** in this embodiment are focused on the region of the renal nerves at the level of the renal blood vessels, the arteries and veins **200**. The focus of the beams can be inside the artery, inside the vein, on the adventitia of the artery or adventitia of the vein.

When applying ultrasonic energy across the skin to the renal artery region, energy densities of potentially over 1 MW/cm² might be required at region of interest in the adventitia of the blood vessel. Typically, however, power densities of 100 W/cm² to 3 kW/cm² would be expected to create the heating required to inhibit these nerves (see Foley et. al. Image-Guided HIFU Neurolysis of Peripheral Nerves To Treat Spasticity And Pain; Ultrasound in Med & Biol. Vol 30 (9) p 1199-1207 herein incorporated by reference). The energy may be pulsed across the skin in an unfocused manner; however, for application of heat, the transducers must be focused otherwise the skin and underlying tissues will receive too much heat. Under imaging with MRI, temperature can be measured with the MRI image. When low energy ultrasound is applied to the region, energy (power) densities in the range of 50 mW/cm² to 500 mW/cm² may be applied. Low energy ultrasound may be enough to stun or partially inhibit the renal nerves particularly when pulsed and depending on the desired clinical result. High intensity ultrasound applied to the region with only a few degrees of temperature rise may have the same effect and this energy range may be in the 0.1 kW/cm² to the 500 kW/cm² range. A train of pulses also might be utilized to augment the effect on nervous tissue. For example, a train of 100 short pulses, each less than a second and applying energy densities of 1 W/cm² to 500 W/cm². In some of the embodiments, cooling may be applied to the skin if the temperature rise is deemed too large to be acceptable. Alternatively, the ultrasound transducers can be pulsed or can be alternated with another set of transducers to effectively spread the heat across the surface of the skin. In some embodiments, the energy is delivered in a pulsed fashion to further decrease the risk to the intervening tissues between the target and the transducer. The pulses can be as close as millisecond, as described, or as long as hours, days or years.

In one method of altering the physiologic process of renal sympathetic excitation, the region around the renal arteries is imaged using CT scan, MRI, thermography, infrared imaging, optical coherence tomography (OCT), photoacoustic imaging, pet imaging, SPECT imaging, or ultrasound, and the images are placed into a three dimensional coordinate reference frame **950**. The coordinate reference frame **950** refers to the knowledge of the relationship between anatomic structures, both two dimensional and three dimensional, the structures placed into a physical coordinate reference. Imaging devices determine the coordinate frame. Once the coordinate frame is established, the imaging and therapy transducers **900**

can be coupled such that the information from the imaging system is utilized by the therapeutic transducers to position the energy. Blood vessels may provide a useful reference frame for deposition of energy as they have a unique imaging signature. An ultrasound pulse echo can provide a Doppler shift signature to identify the blood vessel from the surrounding tissue. In an MRI, CT scan, and even an ultrasound exam, intravenous contrast agents can be utilized to identify flow patterns useful to determine a coordinate reference for energy deposition. Energy transducers **900** which can deliver ultrasound, light, radiation, ionizing radiation, or microwave energy are placed in the same three-dimensional reference frame as the renal arteries, at which time a processor (e.g. using an algorithm) can determine how to direct the transducers to deliver energy to the region **220** of the nerves **910**. The algorithm consists of a targeting feature (planning feature) which allows for prediction of the position and energy deposition of the energy leaving the transducers **900**.

Once the three dimensional coordinate reference frames **950** are linked or coupled, the planning and prediction algorithm can be used to precisely position the energy beams at a target in the body.

The original imaging modality can be utilized to locate the renal sympathetic region can be used to track the motion of the region during treatment. For example, the imaging technology used at time zero is taken as the baseline scan and subsequent scans at time t1 are compared to the baseline scan, t0. The frequency of updates can range from a single scan every few seconds to many scans per second. With ultrasound as the imaging technology, the location might be updated at a frame rate greater than 50 Hz and up to several hundred Hz or thousand Hz. With MRI as the imaging modality, the imaging refresh rate might be closer to 30 Hz. In other embodiments, internally placed fiducials transmit positional information at a high frequency and this information is utilized to fuse the target with an initial external imaging apparatus. Internal fiducials might include one or more imageable elements including doppler signals, regions of blood vessels, ribs, kidneys, and blood vessels and organs other than the target (e.g. vena cava, adrenal gland, ureter). These fiducials can be used to track the region being treated and/or to triangulate to the region to be treated.

In some embodiments (FIG. 3C), a temporary fiducial **960** is placed in the region, such as in the artery **965**, renal vein **975**, aorta **945**, and/or vena cava **985**; such a fiducial is easily imageable from outside the patient.

FIG. 3D depicts an imageable transducer **960** in a blood vessel **967** within a coordinate reference **975** on a monitor system **950**. Alternatively, the temporary fiducial **960** is a transducer which further improves the ability to image and track the region to deliver therapy. The temporary fiducial might be a mechanical, optical, electromechanical, a radiofrequency radiotransmitter, global positioning tracking (GPS) device, or ultrasound responsive technology. Similar devices might be found in U.S. Pat. Nos. 6,656,131 and 7,470,241 which are incorporated by reference herein.

Internal reflections (e.g. speckles) can be tracked as well. These speckles are inherent characteristics of tissue as imaged with ultrasound. They can be tracked and incorporated into treatment planning algorithm and then linked to the therapeutic transducers.

In some embodiments, a test dose of energy can be applied to the renal sympathetic region and then a test performed to determine if an effect was created. For example, a small amount of heat or vibratory energy can be delivered to the region of the sympathetic nerves and then a test of sympathetic activity such as microneurography (detection of sym-

pathetic nerve activity around muscles and nerves which correlate with the beating heart) can be performed. Past research and current clinical data have shown that the sympathetic nerves to the peripheral muscles are affected by interruption of the renal afferent nerves. The degree of temperature rise with the small degree of heat can be determined through the use of MRI thermometry or an ultrasound technique and the temperature rise can be determined or limited to an amount which is reversible.

In another embodiment, a stimulus is applied to a region such as the skin and an output downstream from the skin is detected. For example, a vibratory energy might be applied to the skin and a sympathetic outflow such as the heart rate might be detected. In another embodiment, heat or cold might be applied to the skin and heart rate, blood pressure; vasoconstriction might be detected as an output.

Alternatively, ultrasonic imaging can be utilized to determine the approximate temperature rise of the tissue region. The speed of ultrasonic waves is dependent on temperature and therefore the relative speed of the ultrasound transmission from a region being heated will depend on the temperature, therefore providing measureable variables to monitor. In some embodiments, microbubbles are utilized to determine the rise in temperature. Microbubbles expand and then degrade when exposed to increasing temperature so that they can then predict the temperature of the region being heated. A technique called ultrasound elastography can also be utilized. In this embodiment, the elastic properties of tissue are dependent on temperature and therefore the elastography may be utilized to track features of temperature change. The microbubbles can also be utilized to augment the therapeutic effect of the region being targeted. For example, the microbubbles can be utilized to release a pharmaceutical when the ultrasound reaches them. Alternatively, the microbubble structure can be utilized to enhance imaging of the treatment region to improve targeting or tracking of the treatment region.

In some embodiments, only the temperature determination is utilized. That is, the temperature sensing embodiments and algorithms are utilized with any procedure in which heating is being performed. For example, in a case where heating of the renal nerve region is performed using radiofrequency ablation through the renal artery, imaging of the region from a position external to the patient can be performed while the renal artery region is being heated via radiofrequency methods. Imaging can be accomplished utilizing MRI, ultrasound, infrared, or OCT methods.

In another embodiment, a test may be performed on the baroreceptor complex at the region of the carotid artery bifurcation. After the test dose of energy is applied to the renal artery complex, pressure can be applied to the carotid artery complex; typically, with an intact baroreceptor complex, the systemic blood pressure would decrease after application of pressure to the carotid artery.

However, with renal afferent nerves which have been inhibited, the baroreceptors will not be sensitive to changes in blood pressure and therefore the efficacy of the application of the energy to the renal nerves can be determined. Other tests include attaining indices of autonomic function such as microneurography, autonomic function variability, etc.

In another embodiment, stimulation of the baroreceptor complex is accomplished non-invasively via ultrasound pulses applied externally to the region of the carotid body. The ultrasound pulses are sufficient to stimulate the sinus to affect a blood pressure change, a change which will be affected when an afferent nerve such as the renal afferents have been altered.

More specifically, this methodology is depicted in FIG. 3E. An ultrasound pulse **980** is utilized to stimulate the carotid sinus which will lower blood pressure transiently **982** by activating the baroreceptor complex; activation of the carotid sinus **980** simulates the effect of an increase in blood pressure which leads to a compensatory outflow of parasympathetic activity and decreased sympathetic outflow, subsequently lowering blood pressure. In the instance when the afferent system (e.g. from the kidney) has been inhibited, the pressure will not be modifiable as quickly if at all. In this case, stimulating the baroreceptor complex does not result in a lowering of blood pressure **986**, then the treatment was successful. This diagnostic technique can therefore be utilized to determine the effect of a therapy on a system such as the renal nerve complex. If therapy is successful, then the modifying effect of the ultrasound pulse on the carotid sinus and blood pressure is less dramatic and the therapeutic (treatment of afferent nerves) successful; therefore, therapy can be discontinued **988** temporarily or permanently. If the blood pressure continues to decrease **982** with the baroreceptor stimulation, then the therapeutic effect has not been reached with the therapeutic treatment and it needs to be continued **984** and/or the dose increased. Other methods to stimulate the baroreceptor complex are to apply pressure in the vicinity with hands, compression balloons, and the like.

Other regions of the autonomic nervous system can also be affected directly by the technology described herein by applying energy from one region and transmitted through tissue to another region. For example, FIG. 4a illustrates a system in which energy external to the internal carotid artery **1020** is applied to a portion of the autonomic nervous system, the carotid body complex **1000**, through the internal jugular vein **1005**, and to the carotid body **1000** and/or vagus nerve **1020** region. Ablative energy, vibratory, or electrical stimulation energy can be utilized to affect the transmission of signals to and from these nerves. The transmission in this complex can be augmented, interrupted, inhibited with over-stimulation, or a combination of these effects via energy (e.g. ultrasound, electrical stimulation, etc.).

In addition, or in place of, in other embodiments, energy may be applied to peripheral nerves typically known as motor nerves but which contain autonomic fibers. Such nerves include the saphenous nerve, femoral nerves, lumbar nerves, median nerves, ulnar nerves, and radial nerves. In some embodiments, energy is applied to the nerves and specific autonomic fibers are affected rather than the other neural fibers (e.g. motor or somatic sensory fibers or efferent or afferent autonomic nerves). In some embodiments, other types of autonomic fibers are affected with energy applied internally or externally. For example, nerves surrounding the superior mesenteric artery, the inferior mesenteric artery, the femoral artery, the pelvic arteries, etc. can be affected by the energy in a specific manner so as to create changes in the autonomic responses of the blood vessels themselves or organs related to the blood vessels, the nerves running through and along the vessels to the organs.

In another embodiment, in FIG. 4a, a catheter **1010** is advanced into the internal jugular vein **1005** and when in position, stimulation or ablative energy **1020** is directed toward the autonomic nerves, e.g. the vagus nerve and the carotid sinus/body **1000**, from the catheter positioned in the venous system **1005**.

In a similar type of embodiment **1100**, a catheter based therapeutic energy source **1110** can be inserted into the region of the renal arteries or renal veins (FIG. 4B) to stimulate or inhibit the renal nerves from the inside of the vessel, either the renal artery **1105** or renal vein **1106**. Energy is transferred

through the vessel (e.g. renal vein) to reach the nerves around another vessel (e.g. renal artery). For example, a catheter delivering unfocused ultrasound energy with powers in the range of 50 mW/cm² to 50 kW/cm² can be placed into the renal artery and the energy transmitted radially around the artery or vein to the surrounding nerves. As discussed below, the 500 mW-2500 W/cm² is appropriate to create the specific nerve dysfunction to affect the norepinephrine levels in the kidney, a surrogate of nerve function which has been shown to lead to decreases in blood pressure over time. Pulsed ultrasound, for example, 100 pulse trains with each lasting less than 1 second each, can be applied to the region.

In another embodiment, light is applied through the vessel from within the blood vessel. Infrared, red, blue, and near infrared can all be utilized to affect the function of nerves surrounding blood vessels. For example, a light source is introduced into the renal artery or renal vein **1105**, **1106** and the light transmitted to the region surrounding the blood vessels. In a preferred embodiment, a photosensitizing agent is utilized to hasten the inhibition or destruction of the nerve bundles with this technique. Photosensitizing agents can be applied systemically to infiltrate the region around the blood vessels. Light is then applied from inside the vessel to the region of the nerves outside the vessel. For example, the light source is placed inside the renal vein and then light is transmitted through the vein wall to the adventitial region around the wall activating the photosensitizer and injuring or inhibiting the nerves in the adventitia through an apoptosis pathway. The light source may provide light that is visible, or light that is non-visible.

The therapies in FIGS. 4a-b can be delivered on an acute basis such as for example in an ICU or critical care setting. In such a case, the therapy would be acute and intermittent, with the source outside the patient and the catheter within the patient as shown in FIGS. 4a-b. The therapy can be utilized during times of stress for the patient such that the sympathetic system is slowed down. After the intensive care admission is nearing a close, the catheter and unit can be removed from the patient. In one embodiment, a method is described in which a catheter is placed within a patient to deliver energy to a region of the body sufficient to partially or fully inhibit an autonomic nerve complex during a state of profound sympathetic activation such as shock, sepsis, myocardial infarction, pancreatitis, post-surgical. After the acute phase of implantation during which the sympathetic system is modulated, the device is removed entirely.

FIGS. 5a-b illustrates the eye in close up detail with sympathetic nerves surrounding the posterior of the eye. In the eye, glaucoma is a problem of world-wide importance. The most commonly prescribed medication to treat glaucoma is timoptic, which is a non-selective $\beta 1$ and $\beta 2$ (adrenergic) antagonist. Compliance with this pharmaceutical is a major problem and limits its effectiveness in preventing the complications of glaucoma, the major complication being progression of visual dysfunction.

Ultrasound, or other energy transducers **7000**, can be applied to focus energy from an external region (e.g. a distance from the eye in an external location) anterior to the eye or to a region posteriorly behind the eye **2500** on the sympathetic **2010** or parasympathetic ganglia, all of which will affect lowering of intra-ocular pressure. The energy transducers **7000** apply ablative or near ablative energy to the adventitia of the blood vessels. In some embodiments, the energy is not ablative but vibratory at frequencies (e.g. 1-5 Mhz) and penetration depths (e.g. 0.5 mm to 0.5 cm) sufficient to inhibit the function of the nerves which are responsible for intra-ocular pressure. Lower energy (e.g. sub-ablative) can be

23

applied to the eye to assist in drug delivery or to stimulate tissue healing type of tissue responses.

FIG. 5b depicts the anatomy of the nerves which travel behind the eye 2500. In this illustration, a catheter 2000 is tunneled through the vasculature to the region of the sympathetic nerves surrounding the arteries of the eye 2010 and utilized to ablate, stun, or otherwise modulate the efferent and/or afferent nerves through the wall of the vasculature.

FIG. 6 illustrates an overall schematic of the renal artery, renal vein, the collecting system, and the more distal vessels and collecting system within the renal parenchyma. The individual nerves of the autonomic nervous system typically follow the body vasculature and they are shown in close proximity 3000 to the renal artery as the artery enters the kidney 3100 proper. The hilum of the kidney contains pressure sensors and chemical sensors which influence the inputs to the efferent sympathetic system via afferent nerves traveling from the kidney to the central nervous system and then to the efferent nervous system. Any one or multiple of these structures can influence the function of the kidney. Ablative or non-ablative energy can be applied to the renal vein, the renal artery, the aorta, and/or the vena cava, the renal hilum, the renal parenchyma, the renal medulla, the renal cortex, etc.

In another embodiment, selective lesions, constrictions or implants 3200 are placed in the calyces of the kidney to control or impede blood flow to specific regions of the kidney. Such lesions or implants can be placed on the arterial 3010 or venous sides 3220 of the kidney. In some embodiments, the lesions/implants are created so as to selectively block certain portions of the sympathetic nerves within the kidney. The lesions also may be positioned so as to ablate regions of the kidney which produce hormones, such as renin, which can be detrimental to a patient in excess. The implants or constrictions can be placed in the aorta 3210 or the renal vein 3230. The implants can be active implants, generating stimulating energy chronically or multiple ablative or inhibitory doses discretely over time.

In the renal vein 3230, the implants 3220, 3200 might cause an increase in the pressure within the kidney (by allowing blood flow to back up into the kidney and increase the pressure) which will prevent the downward spiral of systolic heart failure described above because the kidney will act as if it is experiencing a high pressure head. That is, once the pressure in the kidney is restored or artificially elevated by increased venous pressure, the relative renal hypotension signaling to retain electrolytes and water will not be present any longer and the kidney will "feel" full and the renal sympathetic stimulation will be turned off. In one embodiment, a stent which creates a stenosis is implanted using a catheter delivery system. In another embodiment, a stricture 3220 is created using heat delivered either externally or internally. Externally delivered heat is delivered via direct heating via a percutaneous procedure (through the skin to the region of the kidney) or transmitted through the skin (e.g. with HIFU focused through the skin). In one embodiment, an implant is placed between girota's fascia and the cortex of the kidney. The implant can stimulate or inhibit nerves surrounding the renal blood vessels, or even release pharmaceuticals in a drug delivery system.

FIG. 7a depicts at least partial ablation of the renal sympathetic nerves 4400 to the kidney using an imaging system such as an MRI machine or CT scanner 4000. The MRI/CT scan can be linked to a focused ultrasound (HIFU) machine to perform the ablations of the sympathetic nerves 4400 around the region of the renal artery 4500. The MRI/CT scan performs the imaging 4010 and transmits data (e.g. three dimensional representations of the regions of interest) to the ultra-

24

sound controller which then directs the ultrasound to target the region of interest with low intensity ultrasound (50-1000 mW/cm²), heat (>1000 mW/cm²), cavitation, or a combination of these modalities and/or including introduction of enhancing bioactive agent delivery locally or systemically (sonodynamic therapy). Optionally, a doppler ultrasound or other 3D/4D ultrasound is performed and the data pushed to the MRI system to assist with localization of the pathology; alternatively, the ultrasound data are utilized to directly control the direction of the energy being used to target the physiologic processes and CT/MRI is not obtained. Using this imaging and ablation system from a position external to a patient, many regions of the kidney can be treated such as the internal calyces 4350, the cortex 4300, the medulla 4320, the hilum 4330, and the region 4340 close to the aorta.

Further parameters which can be measured include temperature via thermal spectroscopy using MRI or ultrasound thermometry/elastography; thermal imaging is a well-known feature of MRI scanners; the data for thermal spectroscopy exists within the MRI scan and can be extrapolated from the recorded data in real time by comparing regions of interest before and after or during treatment. Temperature data overlaid on the MRI scan enables the operator of the machine to visualize the increase in temperature and therefore the location of the heating to insure that the correct region has indeed been ablated and that excessive energy is not applied to the region. Having temperature data also enables control of the ablation field as far as applying the correct temperature for ablation to the nerves. For example, the temperature over time can be determined and fed back to the operator or in an automated system, to the energy delivery device itself. Furthermore, other spectroscopic parameters can be determined using the MRI scan such as oxygenation, blood flow, or other physiologic and functional parameters. In one embodiment, an alternating magnetic field is used to stimulate and then over-stimulate or inhibit an autonomic nerve (e.g. to or from the kidney).

Elastography is a technique in which the shear waves of the ultrasound beam and reflectance are detected. The tissue characteristics change as the tissue is heated and the tissue properties change. An approximate temperature can be assigned to the tissue based on elastography and the progress of the heating can be monitored.

MRI scanners 4000 generally consist of a magnet and an RF coil. The magnet might be an electromagnet or a permanent magnet. The coil is typically a copper coil which generates a radiofrequency field. Recently, permanent magnets have been utilized to create MRI scanners which are able to be used in almost any setting, for example a private office setting. Office based MRI scanners enable imaging to be performed quickly in the convenience of a physician's office as well as requiring less magnetic force (less than 0.5 Tesla) and as a consequence, less shielding. The lower tesla magnets also provides for special advantages as far as diversity of imaging and resolution of certain features. Importantly, the permanent magnet MRI scanners are open scanners and do not encapsulate the patient during the scan.

In one embodiment, a permanent magnet MRI is utilized to obtain an MRI image of the region of interest 4010. High intensity focused 4100 ultrasound is used to target the region of interest 4600 identified using the MRI. In one embodiment, the MRI is utilized to detect blood flow within one or more blood vessels such as the renal arteries, renal veins, superior mesenteric artery, veins, carotid arteries and veins, aortic arch coronary arteries, veins, to name a subset.

Image 4010 is or can be monitored by a health care professional to ensure that the region of interest is being treated

and the treatment can be stopped if the assumed region is not being treated. Alternatively, an imaging algorithm can be initiated in which the region of interest is automatically (e.g. through image processing) identified and then subsequent images are compared to the initial demarcated region of interest.

Perhaps, most importantly, with MRI, the region around the renal arteries can be easily imaged as can any other region such as the eye, brain, prostate, breast, liver, colon, spleen, aorta, hip, knee, spine, venous tree, and pancreas. The imaging from the MRI can be utilized to precisely focus the ultrasound beam to the region of interest around the renal arteries or elsewhere in the body. With MRI, the actual nerves to be modified or modulated can be directly visualized and targeted with the energy delivered through the body from the ultrasound transducers. One disadvantage of MRI can be the frame acquisition (difficulty in tracking the target) rate as well as the cost of introducing an MRI machine into the treatment paradigm. In these regards, ultrasound imaging offers a much more practical solution.

FIG. 7d depicts a method of treating a region with high intensity focused ultrasound (HIFU). Imaging with an MRI **4520** or ultrasound **4510** (or preferably both) is performed. MRI can be used to directly or indirectly (e.g. using functional MRI or spectroscopy) to visualize the sympathetic nerves. T1 weighted or T2 weighted images can be obtained using the MRI scanner. In addition to anatomic imaging, the MRI scanner can also obtain temperature data regarding the effectiveness of the ablation zone as well as the degree to which the zone is being heated and which parts of the zones are being heated. Other spectroscopic parameters can be added as well such as blood flow and even nerve activity. Ultrasound **4510** can be used to add blood flow to the images using Doppler imaging. The spectroscopic data can be augmented by imaging moieties such as particles, imaging agents, or particles coupled to imaging agents which are injected into the patient intravenously, or locally, and proximal to the region of the renal arteries; these imaging moieties may be visualized on MRI, ultrasound, or CT scan. Ultrasound can also be utilized to determine information regarding heating. The reflectance of the ultrasonic waves changes as the temperature of the tissue changes. By comparing the initial images with the subsequent images after heating, the temperature change which occurred after the institution of heating can be determined.

In one embodiment, the kidneys are detected by a cross-sectional imaging modality such as MRI, ultrasound, or CT scan. The renal arteries and veins are detected within the MRI image utilizing contrast or not utilizing contrast. Next, the imaging data is placed into a three dimensional coordinate system which is linked to one or more ultrasound (e.g. HIFU) transducers **4540** which focus ultrasound onto the region of the renal arteries in the coordinate frame **4530**. The linking, or coupling, of the imaging to the therapeutic transducers is accomplished by determining the 3 dimensional position of the target by creating an anatomic model. The transducers are placed in a relative three dimensional coordinate frame as well. For example, the transducers can be placed in the imaging field **4520** during the MRI or CT scan such that the cross-sectional pictures include the transducers. Optionally, the transducers contain motion sensors, such as electromagnetic, optical, inertial, MEMS, and accelerometers, one or more of which allow for the transducer position to be monitored if for example the body moves relative to the transducer or the operator moves relative to the body. With the motion sensors, the position of the transducers can be determined with movement which might occur during the therapy. The

updated information can then be fed back to the ultrasound therapy device so as to readjust the position of the therapy.

In one embodiment, a system is described in which the blood flow in the renal artery is detected by detecting the walls of the artery or renal vein or the blood flow in the renal artery or the renal vein. The coordinate reference of the blood vessels is then transmitted to the therapeutic transducer, for example, ultrasound. The therapeutic transducer is directed to the renal blood vessels using the information obtained by imaging. A model of the vessels indicates the blood flow of the vessels and the walls of the vessels where the nerves reside. Energy is then applied to the model of the vessels to treat the nerves around the vessels.

Alternatively, in another embodiment, ultrasound is utilized and the ultrasound image **4510** can be directly correlated to the origin of the imaging transducer. The therapeutic transducer **4540** in some embodiments is the same as the imaging transducer and therefore the therapeutic transducer is by definition coupled in a coordinate reference **4540** once the imaging transducer coordinates are known. If the therapeutic transducer and the imaging transducer are different devices, then they can be coupled by knowledge of the relative position of the two devices. The region of interest (ROI) is highlighted in a software algorithm; for example, the renal arteries, the calyces, the medullary region, the cortex, the renal hila, the celiac ganglia, the aorta, or any of the veins of the venous system as well. In another embodiment, the adrenal gland, the vessels traveling to the adrenal gland, or the autonomic nerves traveling to the adrenal gland are targeted with focused ultrasound and then either the medulla or the cortex of the adrenal gland or the nerves and arteries leading to the gland are partially or fully ablated with ultrasonic energy.

The targeting region or focus of the ultrasound is the point of maximal intensity. In some embodiments, targeting focus is placed in the center of the artery such that the walls on either side receive equivalent amounts of energy or power and can be heated more evenly than if one wall of the blood vessel is targeted. In some embodiments in which a blood vessel is targeted, the blood vessel being an artery and the artery having a closely surrounding vein (e.g. the renal artery/vein pedicle), the center of the focus might be placed at the boundary of the vein and the artery.

Once the transducers are energized **4550** after the region is targeted, the tissue is heated **4560** and a technique such as MRI thermography **4570** or ultrasound thermography is utilized to determine the tissue temperature. During the assessment of temperature, the anatomic data from the MRI scan or the Doppler ultrasound is then referenced to ensure the proper degree of positioning and the degree of energy transduction is again further assessed by the modeling algorithm **4545** to set the parameters for the energy transducers **4550**. If there is movement of the target, the transducers may have to be turned off and the patient repositioned. Alternatively, the transducers can be redirected to a different position within the coordinate reference frame.

Ablation can also be augmented using agents such as magnetic nanoparticles or liposomal nanoparticles which are responsive to a radiofrequency field generated by a magnet. These particles can be selectively heated by the magnetic field. The particles can also be enhanced such that they will target specific organs and tissues using targeting moieties such as antibodies, peptides, etc. In addition to the delivery of heat, the particles can be activated to deliver drugs, bioactive agents, or imaging agents at the region at which action is desired (e.g. the renal artery). The particles can be introduced via an intravenous route, a subcutaneous route, a direct injection

tion route through the blood vessel, or a percutaneous route. As an example, magnetic nanoparticles or microparticles respond to a magnetic field by generating heat in a local region around them. Similarly, liposomal particles might have a metallic particle within such that the magnetic particle heats up the region around the liposome but the liposome allows accurate targeting and biocompatibility.

The addition of Doppler ultrasound **4510** may be provided as well. The renal arteries are (if renal arteries or regions surrounding the arteries are the target) placed in a 3D coordinate reference frame **4530** using a software algorithm with or without the help of fiducial markers. Data is supplied to ultrasound transducers **4540** from a heat modeling algorithm **4545** and the transducers are energized with the appropriate phase and power to heat the region of the renal artery to between 40° C. and 90° C. within a time span of several minutes. The position within the 3D coordinate reference is also integrated into the treatment algorithm so that the ultrasound transducers can be moved into the appropriate position. The ultrasound transducers may have frequencies below 1 megahertz (MHz), from 1-20 MHz, or above 30 Mhz, or around 750 kHz, 500 kHz, or 250 kHz. The transducers may be in the form of a phased array, either linear or curved, or the transducers may be mechanically moved so as to focus ultrasound to the target of interest. In addition, MRI thermography **4570** can be utilized so as to obtain the actual temperature of the tissue being heated. These data can be further fed into the system to slow down or speed up the process of ablation **4560** via the transducers **4550**.

Aside from focused ultrasound, ultrasonic waves can be utilized directly to either heat an area or to activate pharmaceuticals in the region of interest. There are several methodologies to enhance drug delivery using focused ultrasound. For example, particles can release pharmaceutical when they are heated by the magnetic field. Liposomes can release a payload when they are activated with focused ultrasound. Ultrasound waves have a natural focusing ability if a transducer is placed in the vicinity of the target and the target contains an activateable moiety such as a bioactive drug or material (e.g. a nanoparticle sensitive to acoustic waves). Examples of sonodynamically activated moieties include some porphyrin derivatives.

So as to test the region of interest and the potential physiologic effect of ablation in that region, the region can be partially heated or vibrated with the focused ultrasound to stun or partially ablate the nerves. Next, a physiologic test such as the testing of blood pressure or measuring norepinephrine levels in the blood, kidney, blood vessels leading to or from the kidney, can be performed to ensure that the correct region was indeed targeted for ablation. Depending on the parameter, additional treatments may be performed.

Clinically, this technique might be called fractionation of therapy which underscores one of the major advantages of the technique to apply external energy versus applying internal energy to the renal arteries. An internal technique requires invasion through the skin and entry into the renal artery lumens which is costly and potentially damaging. Patients will likely not accept multiple treatments, as they are highly invasive and painful. An external technique allows for a less invasive treatment to be applied on multiple occasions, made feasible by the low cost and minimal invasion of the technology described herein.

In another embodiment, a fiducial is utilized to demarcate the region of interest. A fiducial can be intrinsic (e.g. part of the anatomy) or the fiducial can be extrinsic (e.g. placed in position). For example, the fiducial can be an implanted fiducial, an intrinsic fiducial, or device placed in the blood ves-

sels, or a device placed percutaneously through a catheterization or other procedure. The fiducial can also be a bone, such as a rib, or another internal organ, for example, the liver. In one embodiment, the fiducial is a beacon or balloon or balloon with a beacon which is detectable via ultrasound. In one embodiment, the blood flow in the renal arteries, detected via Doppler or B-mode imaging, is the fiducial and its relative direction is determined via Doppler analysis. Next, the renal arteries, and specifically, the region around the renal arteries are placed into a three dimensional coordinate frame utilizing the internal fiducials. A variant of global positioning system technology can be utilized to track the fiducials within the artery or around the arteries. In this embodiment, a position sensor is placed in the artery or vein through a puncture in the groin. The position of the sensor is monitored as the sensor is placed into the blood vessel and its position in physical space relative to the outside of the patient, relative to the operator and relative to the therapeutic transducer is therefore known. The three dimensional coordinate frame is transmitted to the therapeutic ultrasound transducers and then the transducers and anatomy are coupled to the same coordinate frame. At this point, the HIFU is delivered from the transducers, calculating the position of the transducers based on the position of the target in the reference frame.

In one embodiment, a virtual fiducial is created via an imaging system. For example, in the case of a blood vessel such as the renal artery, an image of the blood vessel using B-mode ultrasound can be obtained which correlates to the blood vessel being viewed in direct cross section (**1705**; FIG. **17F**). When the vessel is viewed in this type of view, the center of the vessel can be aligned with the center **1700** of an ultrasound array (e.g. HIFU array **1600**) and the transducers can be focused and applied to the vessel, applying heat lesions **1680** to regions around the vessel **1705**. With different positions of the transducers **1610** along a circumference or hemisphere **1650**, varying focal points can be created **1620**, **1630**, **1640**. The directionality of the transducers allows for a lesion(s) **1620**, **1630**, **1640** which run lengthwise along the vessel **1700**. Thus, a longitudinal lesion **1620-1640** can be produced along the artery to insure maximal inhibition of nerve function. In some embodiments, the center of the therapeutic ultrasound transducer is off center relative to the center of the vessel so that the energy is applied across the vessel wall at an angle, oblique to the vessel.

In this method of treatment, an artery such as a renal artery is viewed in cross-section or close to a cross-section under ultrasound guidance. In this position, the blood vessel is substantially parallel to the axis of the spherical transducer so as to facilitate lesion production. The setup of the ultrasound transducers **1600** has previously been calibrated to create multiple focal lesions **1620**, **1630**, **1640** along the artery if the artery is in cross-section **1680**.

In one embodiment, the fiducial is an intravascular fiducial such as a balloon or a hermetically sealed transmitting device. The balloon is detectable via radiotransmitter within the balloon which is detectable by the external therapeutic transducers. The balloon can have three transducers, each capable of relaying its position so that the balloon can be placed in a three dimensional coordinate reference. Once the balloon is placed into the same coordinate frame as the external transducers using the transmitting beacon, the energy transducing devices can deliver energy (e.g. focused ultrasound) to the blood vessel (e.g. the renal arteries) or the region surrounding the blood vessels (e.g. the renal nerves). The balloon and transmitters also enable the ability to definitively track the vasculature in the case of movement (e.g. the renal arteries).

In another embodiment, the balloon measures temperature or is a conduit for coolant applied during the heating of the artery or nerves.

Delivery of therapeutic ultrasound energy to the tissue inside the body is accomplished via the ultrasound transducers which are directed to deliver the energy to the target in the coordinate frame.

Once the target is placed in the coordinate frame and the energy delivery is begun, it is important to maintain targeting of the position, particularly when the target is a small region such as the sympathetic nerves. To this end, the position of the region of ablation is compared to its baseline position, both in a three dimensional coordinate reference frame. The ongoing positional monitoring and information is fed into an algorithm which determines the new targeting direction of the energy waves toward the target. In one embodiment, if the position is too far from the original position (e.g. the patient moves), then the energy delivery is stopped and the patient repositioned. If the position is not too far from the original position, then the energy transducers can be repositioned either mechanically (e.g. through physical movement) or electrically via phased array (e.g. by changing the relative phase of the waves emanating from the transducers). In another embodiment, multiple transducers are placed on the patient in different positions and each is turned on or off to result in the necessary energy delivery. With a multitude of transducers placed on the patient, a greater territory can be covered with the therapeutic ultrasound. The therapeutic positions can also serve as imaging positions for intrinsic and/or extrinsic fiducials.

In addition to heat delivery, ultrasound can be utilized to deliver cavitating energy which may enable drug delivery at certain frequencies. Cavitating energy can also lead to ablation of tissue at the area of the focus. A systemic dose of a drug can be delivered to the region of interest and the region targeted with the cavitating or other forms of ultrasonic energy. Other types of therapeutic delivery modalities include ultrasound sensitive bubbles or radiation sensitive nanoparticles, all of which enhance the effect of the energy at the target of interest.

FIG. 7E depicts the anatomy of the region **4600**, the kidneys **4620**, renal arteries **4630**, and bony structures **4610**, **4640** as viewed from behind a human patient. FIG. 7E depicts the real world placement of the renal arteries into coordinate frame as outlined in FIG. 7D. Cross sectional CT scans from actual human patients were integrated to create a three-dimensional representation of the renal artery, kidney, and mid-torso region. Plane **4623** is a plane parallel to the transverse processes and angle **4607** is the angle one has to look up in order to “see” the renal artery under the rib.

FIG. 7F depicts an image of the region of the renal arteries and kidney **4605** using ultrasound. The renal hilum containing the arteries and vein **4640** can be visualized using this imaging modality. This image is typical when looking at the kidney and renal artery from the direction and angle depicted in FIG. 7E. Importantly, at the angle **4607** in 7E, there is no rib in the ultrasound path and there no other important structures in the path either.

An ultrasound imaging trial was then performed to detect the available windows to deliver therapeutic ultrasound to the region of the renal arteries **4630** from the posterior region of the patient. It was discovered that the window depicted by arrow **4600** and depicted by arrow **4605** in the cross-sectional ultrasound image from ultrasound (FIG. 7F) provided optimal windows to visualize the anatomy of interest (renal pedicle **4640**).

FIG. 7G contains some of the important data from the trial **4700**, the data in the “standard position **4730**.” These data **4720** can be used to determine the configuration of the clinical HIFU system to deliver ultrasound to the renal hilum. The renal artery **4635** was determined to be 7-17 cm from the skin in the patients on average. The flank to posterior approach was noted to be optimum to image the renal artery, typically through the parenchyma of the kidney as shown in FIG. 7F **4605**. The hilum **4640** of the kidney is approximately 4-8 cm from the ultrasound transducer and the angle of approach **4637** (**4607** in FIG. 7E) relative to an axis defined by the line connecting the two spinous processes and perpendicular to the spine . . . is approximately -10 to -48 degrees. It was also noted that the flank approach through the kidney was the safest approach in that it represents the smallest chances of applying ultrasound to other organs such as bowel.

Upon further experimentation, it was discovered that by positioning the patient in the prone position (backside up, abdomen down), the structures under study **4750** . . . that is, the renal arteries **4770** and **4780**, the kidney hilum were even closer to the skin and the respiratory motion of the artery and kidney was markedly decreased. FIG. 7H depicts these results **4750**, **4760** showing the renal artery **4770** at 6-10 cm and the angle of approach **4790** relative to the spine **4607** shallower at -5 to -20 degrees.

Therefore, with these clinical data, in one embodiment, a method of treatment **4800** (FIG. 7I) of the renal nerves in a patient has been devised: 1) identify the rib **4810** and iliac crest **4840** of a patient on the left and right flank of the patient **4810**; 2) identify the left or right sided kidney with ultrasound **4820**; 3) identify the hilum of the kidney and the extent the renal hilum is visible along surface of patient **4820** using an imaging technology; 4) identify the blood vessels leading to the kidney from one or more angles, extracting the extent of visibility **4860** along the surface area of the patient’s back; 5) determine the distance to the one or more of the renal artery, renal vein, kidney, and the renal hilum **4850**; 6) optionally, position patient in the prone position with a substantive positioning device underneath the back of the patient or overtop the abdomen of the patient **4830**, to optimize visibility; 7) optionally determine, through modeling, the required power to obtain a therapeutic dose at the renal hilum and region around the renal blood vessels; 8) apply therapeutic energy to renal blood vessels; 9) optionally track the region of the blood vessels to ensure the continued delivery of energy to the region as planned in the modeling; 10) optionally, turning off delivery of energy in the case the focus of the energy is outside of the planned region.

FIG. 8A depicts a percutaneous procedure and device **5010** in which the region around the renal artery **5030** is directly approached through the skin from an external position. A combination of imaging and application of energy (e.g. ablation) may be performed to ablate the region around the renal artery to treat hypertension, end stage renal disease, and heart failure. Probe **5010** is positioned through the skin and in proximity to the kidney **5030**. The probe may include sensors at its tip **5020** which detect heat or temperature or may enable augmentation of the therapeutic energy delivery. Ablative, ionizing energy, heat, or light may be applied to the region to inhibit the sympathetic nerves around the renal artery using the probe **5010**. Ultrasound, radiofrequency, microwave, direct heating elements, and balloons with heat or energy sources may be applied to the region of the sympathetic nerves. Imaging may be included on the probe or performed separately while the probe is being applied to the region of the renal blood vessels.

31

In one embodiment, the percutaneous procedure in FIG. 8A is performed under MRI, CT, or ultrasound guidance to obtain localization or information about the degree of heat being applied. In one embodiment, ultrasound is applied but at a sub-ablative dose. That is, the energy level is enough to damage or inhibit the nerves but the temperature is such that the nerves are not ablated but paralyzed or partially inhibited by the energy. A particularly preferred embodiment would be to perform the procedure under guidance from an MRI scanner because the region being heated can be determined anatomically in real time as well via temperature maps. As described above, the images after heating can be compared to those at baseline and the signals are compared at the different temperatures.

In one embodiment, selective regions of the kidney are ablated through the percutaneous access route; for example, regions which secrete hormones which are detrimental to a patient or to the kidneys or other organs. Using energy applied externally to the patient through the skin and from different angles affords the ability to target any region in or on the kidney or along the renal nerves or at the region of the adrenal gland, aorta, or sympathetic chain. This greater breadth in the number of regions to be targeted is enabled by the combination of external imaging and external delivery of the energy from a multitude of angles through the skin of the patient and to the target. The renal nerves can be targeted at their takeoff from the aorta onto the renal artery, at their synapses at the celiac ganglia, or at their bifurcation point along the renal artery.

In a further embodiment, probe 5010 can be utilized to detect temperature or motion of the region while the ultrasound transducers are applying the energy to the region. A motion sensor, position beacon, or accelerometer can be used to provide feedback for the HIFU transducers. In addition, an optional temperature or imaging modality may be placed on the probe 5010. The probe 5010 can also be used to locate the position within the laparoscopic field for the ablations to be performed. The dose delivered by this probe is approximately

In FIG. 8B, intravascular devices 5050, 5055 are depicted which apply energy to the region around the renal arteries 5065 from within the renal arteries. The intravascular devices can be utilized to apply radiofrequency, ionizing radiation, and/or ultrasound (either focused or unfocused) energy to the renal artery and surrounding regions. MRI or ultrasound or direct thermometry can be further utilized to detect the region where the heat is being applied while the intravascular catheter is in place.

In one embodiment, devices 5050, 5055 (FIG. 8B) apply ultrasound energy which inhibits nerve function not by heating, but by mechanisms such as periodic pressure changes, radiation pressure, streaming or flow in viscous media, and pressures associated with cavitation, defined as the formation of holes in liquid media. Heat can selectively be added to these energies but not to create a temperature which ablates the nerves, only facilitates the mechanism of vibration and pressure. In this embodiment, the ultrasound is not focused but radiates outward from the source to essentially create a cylinder of ultrasonic waves that intersect with the wall of the blood vessel. An interfacial material between the ultrasound transducer and the wall of the artery may be provided such that the ultrasound is efficiently transducted through the arterial wall to the region of the nerves around the artery. In another embodiment, the ultrasound directly enters the blood and propagates through the ultrasound wall to affect the nerves. In some embodiments, cooling is provided around the ultrasound catheter which protects the inside of the vessel yet allows the ultrasound to penetrate through the wall to the

32

regions outside the artery. A stabilization method for the ultrasound probe is also included in such a procedure. The stabilization method might include a stabilizing component added to the probe and may include a range finding element component of the ultrasound so that the operator knows where the ultrasound energy is being applied.

Imaging can be performed externally or internally in this embodiment in which a catheter is placed inside the renal arteries. For example, external imaging with MRI or Ultrasound may be utilized to visualize changes during the ultrasound modulation of the nerve bundles. Indeed, these imaging modalities may be utilized for the application of any type of energy within the wall of the artery. For example, radiofrequency delivery of energy through the wall of the renal artery may be monitored through similar techniques. Thus the monitoring of the procedural success of the technique is independent of the technique in most cases.

Alternatively, in another embodiment, the devices 5050, 5055 can be utilized to direct externally applied energy (e.g. ultrasound) to the correct place around the artery as the HIFU transducers deliver the energy to the region. For example, the intravascular probe 5050 can be utilized as a homing beacon for the imaging/therapeutic technology utilized for the externally delivered HIFU.

FIG. 8C depicts a percutaneous procedure to inhibit the renal sympathetic nerves. Probe 5010 is utilized to approach the renal hilum 5060 region from posterior and renal artery 5065. With the data presented below, the probe can be armed with HIFU to denervate the region. The data presented below indicates the feasibility of this approach as far as ultrasound enabling denervation of the vessels quickly and easily.

In another embodiment, the physiologic process of arterial expansion (aneurysms) is targeted. In FIG. 9a, an ultrasound transducer is 6005 is placed near the wall of an aneurysm 6030. Ultrasonic energy 6015 is applied to the wall 6030 of the aneurysm to thicken the wall and prevent further expansion of the aneurysm. In some embodiments, clot within the aneurysm is targeted as well so that the clot is broken up or dissolved with the ultrasonic energy. Once the wall of the aneurysm is heated with ultrasonic energy to a temperature of between 40 and 70 degrees, the collagen, elastin, and other extracellular matrix in the wall will harden as it cools, thereby preventing the wall from further expansion.

In another embodiment, a material is placed in the aneurysm sac and the focused or non-focused ultrasound utilized to harden or otherwise induce the material in the sac to stick to the aorta or clot in the aneurysm and thus close the aneurysm permanently. In one embodiment therefore, an ultrasound catheter is placed in an aorta at the region of an aneurysm wall or close to a material in an aneurysmal wall. The material can be a man-made material placed by an operator or it can be material such as thrombus which is in the aneurysm naturally. Ultrasound is applied to the wall, or the material, resulting in hardening of the wall or of the material, strengthening the aneurysm wall and preventing expansion. The energy can also be applied from a position external to the patient or through a percutaneously positioned energy delivering catheter.

FIG. 9b 6000 depicts a clot prevention device 6012 (vena cava filter) within a blood vessel such as the aorta or vena cava 6010. The ultrasound catheter 6005 is applied to the clot prevention device (filter) 6012 so as to remove the clot from the device or to free the device 6012 from the wall of the blood vessel in order to remove it from the blood vessel 6000.

FIG. 9c depicts a device and method in which the celiac plexus 6020 close to the aorta 6000 is ablated or partially heated using heat or vibrational energy from an ultrasonic

energy source **6005** which can apply focused or unfocused sound waves **6007** at frequencies ranging from 20 kilohertz to 5 Mhz and at powers ranging from 1 mW to over 100 kW in a focused or unfocused manner. Full, or partial ablation of the celiac plexus **6020** can result in a decrease in blood pressure via a similar mechanism as applying ultrasonic energy to the renal nerves; the ablation catheter is a focused ultrasound catheter but can also be a direct (unfocused) ultrasonic, a microwave transducer, or a resistive heating element. Energy can also be delivered from an external position through the skin to the aorta or celiac plexus region.

FIG. **10** depicts a method **6100** to treat a patient with high intensity or low intensity focused ultrasound (HIFU or LIFU) **6260**. In a first step, a CT and/or MRI scan and/or thermography and/or ultrasound (1D,2D,3D) is performed **6110**. A fiducial or other marking on or in the patient **6120** is optionally used to mark and track **6140** the patient. The fiducial can be an implanted fiducial, a temporary fiducial placed internally or externally in or on the patient, or a fiducial intrinsic to the patient (e.g. bone, blood vessel, arterial wall) which can be imaged using the CT/MRI/Ultrasound devices **6110**. The fiducial can further be a temporary fiducial such as a catheter temporarily placed in an artery or vein of a patient or a percutaneously placed catheter. A planning step **6130** for the HIFU treatment is performed in which baseline readings such as position of the organ and temperature are determined; a HIFU treatment is then planned using a model (e.g. finite element model) to predict heat transfer, or pressure to heat transfer, from the ultrasound transducers **6130**. The planning step incorporates the information on the location of the tissue or target from the imaging devices **6110** and allows placement of the anatomy into a three dimensional coordinate reference such that modeling **6130** can be performed.

The planning step **6130** includes determination of the positioning of the ultrasound transducers as far as position of the focus in the patient. X,Y,Z, and up to three angular coordinates are used to determine the position of the ultrasonic focus in the patient based on the cross sectional imaging **6110**. The HIFU transducers might have their own position sensors built in so that the position relative to the target can be assessed. Alternatively, the HIFU transducers can be rigidly fixed to the table on which the patient rests so that the coordinates relative to the table and the patient are easily obtainable. The flow of heat is also modeled in the planning step **6130** so that the temperature at a specific position with the ultrasound can be planned and predicted. For example, the pressure wave from the transducer is modeled as it penetrates through the tissue to the target. For the most part, the tissue can be treated as water with a minimal loss due to interfaces. Modeling data predicts that this is the case. The relative power and phase of the ultrasonic wave at the target can be determined by the positional coupling between the probe and target. A convective heat transfer term is added to model heat transfer due to blood flow, particularly in the region of an artery. A conductive heat transfer term is also modeled in the equation for heat flow and temperature.

Another variable which is considered in the planning step is the size of the lesion and the error in its position. In the ablation of small regions such as nerves surrounding blood vessels, the temperature of the regions may need to be increased to a temperature of 60-90 degrees Celsius to permanently ablate nerves in the region. Temperatures of 40-60 degrees may temporarily inhibit or block the nerves in these regions and these temperatures can be used to determine that a patient will respond to a specific treatment without permanently ablating the nerve region. Subsequently, additional

therapy can be applied at a later time so as to complete the job or perhaps, re-inhibit the nerve regions.

An error analysis is also performed during the treatment contemplated in FIG. **10**. Each element of temperature and position contains an error variable which propagates through the equation of the treatment. The errors are modeled to obtain a virtual representation of the temperature mapped to position. This map is correlated to the position of the ultrasound transducers in the treatment of the region of interest.

During the delivery of the treatment **6260**, the patient may move, in which case the fiducials **6120** track the movement and the position of the treatment zone is re-analyzed **6150** and the treatment is restarted or the transducers are moved either mechanically or electrically to a new focus position.

In another embodiment, a cross-sectional technique of imaging is used in combination with a modality such as ultrasound to create a fusion type of image. The cross-sectional imaging is utilized to create a three dimensional data set of the anatomy. The ultrasound, providing two dimensional images, is linked to the three dimensional imaging provided by the cross-sectional machine through fiducial matches between the ultrasound and the MRI. As a body portion moves within the ultrasound field, the corresponding data is determined (coupled to) the cross-sectional (e.g. MRI image) and a viewing station can show the movement in the three dimensional dataset. The ultrasound provides real time images and the coupling to the MRI or other cross-sectional image depicts the ultrasound determined position in the three dimensional space.

FIG. **11** depicts the treatment **7410** of another disease in the body of a patient, this time in the head of a patient. Subdural and epidural hematomas occur as a result of bleeding of blood vessels in the dural or epidural spaces of the brain, spinal column, and scalp. FIG. **11** depicts a CT or MRI scanner **7300** and a patient **7400** therein. An image is obtained of the brain **7000** using a CT or MRI scan. The image is utilized to couple the treatment zone **7100** to the ultrasound array utilized to heat the region. In one embodiment **7100**, a subdural hematoma, either acute or chronic, is treated. In another embodiment **7200**, an epidural hematoma is treated. In both embodiments, the region of leaking capillaries and blood vessels are heated to stop the bleeding, or in the case of a chronic subdural hematoma, the oozing of the inflammatory capillaries.

In an exemplary embodiment of modulating physiologic processes, a patient **7400** with a subdural or epidural hematoma is chosen for treatment and a CT scan or MRI **7300** is obtained of the treatment region. Treatment planning ensues and the chronic region of the epidural **7200** or subdural **7010** hematoma is targeted for treatment with the focused ultrasound **7100** transducer technology. Next the target of interest is placed in a coordinate reference frame as are the ultrasound transducers. Therapy **7100** ensues once the two are coupled together. The focused ultrasound heats the region of the hematoma to dissolve the clot and/or stop the leakage from the capillaries which lead to the accumulation of fluid around the brain **7420**. The technology can be used in place of or in addition to a burr hole, which is a hole placed through the scalp to evacuate the fluid.

FIG. **12** depicts a laparoscopic based approach **8000** to the renal artery region in which the sympathetic nerves **8210** can be ligated, interrupted, or otherwise modulated. In laparoscopy, the abdomen of a patient is insufflated and laparoscopic instruments introduced into the insufflated abdomen. The retroperitoneum is easily accessible through a flank approach or (less so) through a transabdominal (peritoneal) approach. A laparoscopic instrument **8200** with a distal tip **8220** can

apply heat or another form of energy or deliver a drug to the region of the sympathetic nerves **8210**. The laparoscopic instrument can also be utilized to ablate or alter the region of the celiac plexus **8300** and surrounding ganglia. The laparoscope can have an ultrasound transducer **8220** attached, a temperature probe attached, a microwave transducer attached, or a radiofrequency transducer attached. The laparoscope can be utilized to directly ablate or stun the nerves (e.g. with a lower frequency/energy) surrounding vessels or can be used to ablate or stun nerve ganglia which travel with the blood vessels. Similar types of modeling and imaging can be utilized with the percutaneous approach as with the external approach to the renal nerves. With the discovery through animal experimentation (see below) that a wide area of nerve inhibition can be affected with a single ultrasound probe in a single direction (see above), the nerve region does not have to be directly contacted with the probe, the probe instead can be directed in the general direction of the nerve regions and the ultrasound delivered. For example, the probe can be placed on one side of the vessel and activated to deliver focused or semi-focused ultrasound over a generalized region which might not contain greater than 1 cm of longitudinal length of the artery but its effect is enough to completely inhibit nerve function along.

FIG. **13** depicts an algorithm **8400** for the treatment of a region of interest using directed energy from a distance. MRI and/or CT with or without an imaging agent **8410** can be utilized to demarcate the region of interest (for example, the ablation zone) and then ablation **8420** can be performed around the zone identified by the agent using any of the modalities above. This algorithm is applicable to any of the therapeutic modalities described above including external HIFU, laparoscopic instruments, intravascular catheters, percutaneous catheters and instruments, as well as any of the treatment regions including the renal nerves, the eye, the kidneys, the aorta, or any of the other nerves surrounding peripheral arteries or veins. Imaging **8430** with CT, MRI, ultrasound, or PET can be utilized in real time to visualize the region being ablated. At such time when destruction of the lesion is complete **8440**, imaging with an imaging (for example, a molecular imaging agent or a contrast agent such as gadolinium) agent **8410** can be performed again. The extent of ablation can also be monitored by monitoring the temperature or the appearance of the ablated zone under an imaging modality. Once lesion destruction is complete **8440**, the procedure is finished. In some embodiments, ultrasonic diagnostic techniques such as elastography are utilized to determine the progress toward heating or ablation of a region.

FIG. **14** depicts ablation in which specific nerve fibers of a nerve are targeted using different temperature gradients, power gradients, or temperatures **8500**. For example, if temperature is determined by MRI thermometry or with another technique such as ultrasound, infrared thermography, or a thermocouple, then the temperature can be kept at a temperature in which only certain nerve fibers are targeted for destruction or inhibition. Alternatively, part or all of the nerve can be turned off temporarily to then test the downstream effect of the nerve being turned off. For example, the sympathetic nerves around the renal artery can be turned off with a small amount of heat or other energy (e.g. vibrational energy) and then the effect can be determined. For example, norepinephrine levels in the systemic blood, kidney, or renal vein can be assayed; alternatively, the stimulation effect of the nerves can be tested after temporary cessation of activity (e.g. skin reactivity, blood pressure lability, cardiac activity, pulmonary activity, renal artery constriction in response to renal nerve stimulation). For example, in one embodiment, the

sympathetic activity within a peripheral nerve is monitored; sympathetic activity typically manifests as spikes within a peripheral nerve electrical recording. The number of spike correlates with the degree of sympathetic activity or over-activity. When the activity is decreased by (e.g. renal artery de-inervation), the concentration of spikes in the peripheral nerve train is decreased, indicating a successful therapy of the sympathetic or autonomic nervous system. Varying frequencies of vibration can be utilized to inhibit specific nerve fibers versus others. For example, in some embodiments, the efferent nerve fibers are inhibited and in other embodiments, the afferent nerve fibers are inhibited. In some embodiments, both types of nerve fibers are inhibited, temporarily or permanently. In some embodiments, the C fibers **8520** are selectively blocked at lower heat levels than the A nerve fibers. In other embodiment, the B fibers are selectively treated or blocked and in some embodiments, the A fibers **8530** are preferentially blocked. In some embodiments, all fibers are inhibited by suturing the nerve with a high dose of ultrasound **8510**. Based on the experimentation described above, the power density to achieve full blockage might be around 100-800 W/cm² or with some nerves from about 500 to 2500 W/cm². In some embodiments, a pulse train of 100 or more pulses each lasting 1-2 seconds (for example) and delivering powers from about 50 w/cm² to 500 W/cm². Indeed, prior literature has shown that energies at or about 100 W/cm² is adequate to destroy or at least inhibit nerve function (Lele, PP. Effects of Focused Ultrasound Radiation on Peripheral Nerve, with Observations on Local Heating. Experimental Neurology 8, 47-83 1963 incorporated by reference).

FIG. **15a** depicts treatment **8600** of a vertebral body or intervertebral disk **8610** in which nerves within **8640** or around the vertebral column **8630** are targeted with energy **8625** waves. In one embodiment, nerves around the facet joints are targeted. In another embodiment, nerves leading to the disks or vertebral endplates are targeted. In another embodiment, nerves within the vertebral bone **8630** are targeted by heating the bone itself. Sensory nerves run through canals **8635** in the vertebral bone **8630** and can be inhibited or ablated by heating the bone **8630**.

FIG. **15B** depicts a close-up of the region of the facet joint. Focused ultrasound to this region can inhibit nerves involved in back pain which originate at the dorsal root nerve and travel to the facet joint **8645**. Ablation or inhibition of these nerves can limit or even cure back pain due to facet joint arthropathy. Focused ultrasound can be applied to the region of the facet joint from a position outside the patient to the facet joint using powers of between 100 W/cm² and 2500 W/cm² at the nerve from times ranging from 1 second to 10 minutes.

FIG. **16A** depicts a set of lesion types, sizes, and anatomies **8710a-f** which lead to de-innervation of the different portions of the sympathetic nerve tree around the renal artery. For example, the lesions can be annular, cigar shaped, linear, doughnut and/or spherical; the lesions can be placed around the renal arteries **8705**, inside the kidney **8710**, and/or around the aorta **8700**. For example, the renal arterial tree comprises a portion of the aorta **8700**, the renal arteries **8705**, and kidneys **8715**. Lesions **8714** and **8716** are different types of lesions which are created around the aorta **8700** and vascular tree of the kidneys. Lesions **8712** and **8718** are applied to the pole branches from the renal artery leading to the kidney and inhibit nerve functioning at branches from the main renal artery. These lesions also can be applied from a position external to the patient. Lesions can be placed in a spiral shape **8707** along the length of the artery as well. These lesions can be produced using energy delivered from outside the blood vessels using a completely non-invasive approach in which

the ultrasound is applied through the skin to the vessel region or the energy can be delivered via percutaneous approach. Either delivery method can be accomplished through the posterior approach to the blood vessels as discovered and described above.

In one method therefore, ultrasound energy can be applied to the blood vessel leading to a kidney in a pattern such that a circular pattern of heat and ultrasound is applied to the vessel. The energy is transmitted through the skin in one embodiment or through the artery in another embodiment. As described below, ultrasound is transmitted from a distance and is inherently easier to apply in a circular pattern because it doesn't only rely on conduction.

Previously, it was unknown and undiscovered whether or not the annular shaped lesions as shown in FIG. 16A would have been sufficient to block nerve function of the autonomic nerves around the blood vessels. Applicant of the subject application discovered that the annular shaped ablations 8710 not only block function but indeed completely block nerve function around the renal artery and kidney and with very minimal damage (FIG. 16C), if any, to the arteries and veins themselves. In these experiments, focused ultrasound was used to block the nerves; the ultrasound was transmitted through and around the vessel from the top (that is, only one side of the vessel) at levels of 200-2500 W/cm². Simulations are shown in FIG. 16B and described below. Norepinephrine levels in the kidney 8780, which are utilized to determine the degree of nerve inhibition, were determined before and after application of energy. The lower the levels of norepinephrine, the more nerves which have been inhibited. In these experiments which were performed, the norepinephrine levels approached zero 8782 versus controls 8784 which remained high. In fact, the levels were equal to or lower than the surgically denuded blood vessels (surgical denudement involves directly cutting the nerves surgically). It is important that the renal artery and vein walls were remained substantially unharmed; this is likely due to the fact that the quick arterial blood flow removes heat from the vessel wall and the fact that the main renal artery is extremely resilient due to its large size, high blood flow, and thick wall. To summarize, ultrasound (focused and relatively unfocused) was applied to one side of the renal artery and vein complex. The marker of nerve inhibition, norepinephrine levels inside the kidney, were determined to be approaching zero after application to the nerves from a single direction, transmitting the energy through the artery wall to reach nerves around the circumference of the artery. The level of zero norepinephrine 8782 indicates essentially complete abolition of nerve function proving that the annular lesions were in fact created as depicted in FIG. 16A and simulated in FIG. 16B. Histological results also confirm the annular nature of the lesions and limited collateral damage as predicted by the modeling in 16B.

Therefore, in one embodiment, the ultrasound is applied from a position external to the artery in such a manner so as to create an annular or semi-annular rim of heat all the way around the artery to inhibit, ablate, or partially ablate the autonomic nerves surrounding the artery. The walls or the blood flow of the artery can be utilized to target the ultrasound to the nerves which, if not directly visualized, are visualized by use of a model to approximate the position of the nerves based on the position of the blood vessel.

FIG. 16B further supports the physics and physiology described herein, depicting a theoretical simulation 8750 of the physical and animal experimentation described above. That is, focused ultrasound was targeted to a blood vessel in a computer simulation 8750. The renal artery 8755 is depicted

within the heating zone generated within a focused ultrasound field. Depicted is the temperature at <1s 8760 and at approximately 5s 8765 and longer time >10s 8767. Flow direction 8770 is shown as well. The larger ovals depict higher temperatures with the central temperature >100° C. The ultrasound field is transmitted through the artery 8755, with heat building up around the artery as shown via the temperature maps 8765. Importantly, this theoretical simulation also reveals the ability of the ultrasound to travel through the artery and affect both walls of the blood vessel. These data are consistent with the animal experimentation described above, creating a unified physical and experimental dataset.

Therefore, based on the animal and theoretical experimentation, there is proven feasibility of utilizing ultrasound to quickly and efficiently inhibit the nerves around the renal arteries from a position external to the blood vessels as well as from a position external to the skin of the patient.

Utilizing the experimental simulations and animal experimentation described above, a clinical device can and has been devised and tested in human patients. FIG. 17A depicts a multi-transducer HIFU device 1100 which applies a finite lesion 1150 along an artery 1140 (e.g. a renal artery) leading to a kidney 1130. The lesion can be spherical in shape, cigar shaped 1150, annular shaped 8710 (FIG. 16A), or point shaped; however, in a preferred embodiment, the lesion runs along the length of the artery and has a cigar shaped 1150. This lesion is generated by a spherical or semi-spherical type of ultrasound array in a preferred embodiment. Multiple cigar shaped lesion as shown in FIG. 17C leads to a ring type of lesion 1350.

FIG. 17B depicts an imaging apparatus display which monitors treatment. Lesion 1150 is depicted on the imaging apparatus as is the aorta 1160 and renal artery 1155. The image might depict heat, tissue elastography, vibrations, or might be based on a simulation of the position of the lesion 1150. FIG. 17C depicts another view of the treatment monitoring, with the renal artery in cross section 1340. Lesion 1350 is depicted in cross section in this image as well. The lesion 1350 might be considered to circumscribe the vessel 1340 in embodiments where multiple lesions are applied.

FIG. 17D depicts a methodology 1500 to analyze and follow the delivery of therapeutic focused ultrasound to an arterial region. A key step is to first position 1510 the patient optimally to image the treatment region; the imaging of the patient might involve the use of Doppler imaging, M mode imaging, A scan imaging, or even MRI or CT scan. The imaging unit is utilized to obtain coordinate data 1530 from the doppler shift pattern of the artery. Next, the focused ultrasound probe is positioned 1520 relative to the imaged treatment region 1510 and treatment can be planned or applied.

FIG. 17E depicts the pathway of the acoustic waves from a spherical or cylindrical type of ultrasound array 1600. In some embodiments, the transducer is aspherical such that a sharp focus does not exist but rather the focus is more diffuse in nature or off the central axis. Alternatively, the asphericity might allow for different pathlengths along the axis of the focusing. For example, one edge of the ultrasound transducer might be called upon for 15 cm of propagation while another edge of the transducer might be called upon to propagate only 10 cm, in which case a combination of difference frequencies or angles might be required.

Ultrasound transducers 1610 are aligned along the edge of a cylinder 1650, aimed so that they intersect at one or more focal spots 1620, 1630, 1640 around the vessel (e.g. renal artery). The transducers 1610 are positioned along the cylinder or sphere or spherical approximation (e.g. aspherical) 1650 such that several of the transducers are closer to one

focus or the other such that a range of distances **1620**, **1630**, **1640** to the artery is created. The patient and artery are positioned such that their centers **1700** co-localize with the center of the ultrasound array **1600**. Once the centers are co-localized, the HIFU energy can be activated to create lesions along the length of the artery wall **1640**, **1620**, **1630** at different depths and positions around the artery. The natural focusing of the transducers positioned along a cylinder as in FIG. **17E** is a lengthwise lesion, longer than in thickness or height, which will run along the length of an artery **1155** when the artery **1340** is placed along the center axis of the cylinder. When viewed along a cross section (FIG. **17F**), the nerve ablations are positioned along a clock face **1680** around the blood vessel.

In another embodiment, a movement system for the transducers is utilized so that the transducers move along the rim of the sphere or cylinder to which they are attached. The transducers can be moved automatically or semi-automatically, based on imaging or based on external position markers. The transducers are independently controlled electrically but coupled mechanically through the rigid structure.

Importantly, during treatment, a treatment workstation **1300** (FIG. **17C**) gives multiple views of the treatment zone with both physical appearance and anatomy **1350**. Physical modeling is performed in order to predict lesion depth and the time to produce the lesion; this information is fed back to the ultrasound transducers **1100**. The position of the lesion is also constantly monitored in a three dimensional coordinate frame and the transducer focus at lesions center **1150** in the context of monitoring **1300** continually updated.

In some embodiments, motion tracking prevents the lesion or patient from moving too far out of the treatment zone during the ablation. If the patient does move outside the treatment zone during the therapy, then the therapy can be stopped. Motion tracking can be performed using the ultrasound transducers, tracking frames and position or with transducers from multiple angles, creating a three dimensional image with the transducers. Alternatively, a video imaging system can be used to track patient movements, as can a series of accelerometers positioned on the patient which indicate movement.

FIG. **18** depicts a micro-catheter **8810** which can be placed into renal calyces **8820**; this catheter allows the operator to specifically ablate or stimulate **8830** regions of the kidney **8800**. The catheter can be used to further allow for targeting of the region around the renal arteries and kidneys by providing additional imaging capability or by assisting in movement tracking or reflection of the ultrasound waves to create or position the lesion. The catheter or device at or near the end of the catheter may transmit signals outside the patient to direct an energy delivery device which delivers energy through the skin. Signaling outside the patient may comprise energies such as radiofrequency transmission outside the patient or radiofrequency from outside to the inside to target the region surrounding the catheter. The following patent and patent applications describe the delivery of ultrasound using a targeting catheter within a blood vessel, and are expressly incorporated by reference herein:

U.S. patent application Ser. Nos. 11/583,569, 12/762,938, 11/583,656, 12/247,969, 10/633,726, 09/721,526, 10/780, 405, 09/747,310, 12/202,195, 11/619,996, 09/696,076

In one system **8800**, a micro catheter **8810** is delivered to the renal arteries and into the branches of the renal arteries in the kidney **8820**. A signal is generated from the catheter into the kidney and out of the patient to an energy delivery system. Based on the generated signal, the position of the catheter in a three dimensional coordinate reference is determined and

the energy source is activated to deliver energy **8830** to the region indicated by the microcatheter **8810**.

In an additional embodiment, station keeping is utilized. Station keeping enables the operator to maintain the position of the external energy delivery device with respect to the movement of the operator or movement of the patient. As an example, targeting can be achieved with the energy delivery system and

The microcatheter may be also be utilized to place a flow restrictor inside the kidney (e.g. inside a renal vein) to "trick" the kidney into thinking its internal pressure is higher than it might be. In this embodiment, the kidney generates signals to the central nervous system to lower sympathetic output to target organs in an attempt to decrease its perfusion pressure.

Alternatively, specific regions of the kidney might be responsible for hormone excretion or other factors which lead to hypertension or other detrimental effects to the cardiovascular system. The microcatheter can generate ultrasound, radiofrequency, microwave, or X-ray energy.

The microcatheter can be utilized to ablate regions in the renal vein or intra-parenchymal venous portion as well. In some embodiments, ablation is not required but vibratory energy emanating from the probe is utilized to affect, on a permanent or temporary basis, the mechanoreceptors or chemoreceptors in the location of the hilum of the kidney.

FIG. **19A** depicts the application **8900** of energy to the region of the renal artery **8910** and kidney **8920** using physically separated transducers **8930**, **8931**. Although two are shown, the transducer can be a single transducer which is connected all along. The transducer(s) can be spherical or aspherical, they can be couple to an imaging transducer directly or indirectly where the imaging unit might be separated at a distance. In contrast to the delivery method of FIG. **17**, FIG. **19A** depicts delivery of ultrasound transverse to the renal arteries and not longitudinal to the artery. The direction of energy delivery is the posterior of the patient because the renal artery is the first vessel "seen" when traveling from the skin toward the anterior direction facilitating delivery of the therapy. In one embodiment, the transducers **8930**, **8931** are placed under, or inferior to the rib of the patient or between the ribs of a patient; next, the transducers apply an ultrasound wave propagating forward toward the anterior abdominal wall and image the region of the renal arteries and renal veins, separating them from one another. In some embodiments, such delivery might be advantageous, if for example, a longitudinal view of the artery is unobtainable or a faster treatment paradigm is desirable. The transducers **8930**, **8931** communicate with one another and are connected to a computer model of the region of interest being imaged (ROI), the ROI based on an MRI scan performed just prior to the start of the procedure and throughout the procedure. Importantly, the transducers are placed posterior in the cross section of the patient, an area with more direct access to the kidney region. The angle between the imaging transducers can be as low as 3 degrees or as great as 180 degrees depending on the optimal position in the patient.

In another embodiment, an MRI is not performed but ultrasound is utilized to obtain all or part of the cross-sectional view in FIG. **19A**. For example, **8930** might contain an imaging transducer as well as a therapeutic energy source (e.g. ionizing energy, HIFU, low energy focused ultrasound, etc.)

FIG. **19B** depicts an ultrasound image from a patient illustrating imaging of the region with patient properly positioned as described below. It is this cross section that can be treated with image guided HIFU of the renal hilum region. The kidney **8935** is visualized in cross section and ultrasound then travels through to the renal artery **8937** and vein **8941**. The

41

distance can be accurately measure **8943** with ultrasound (in this case 8 cm **8943**). This information is useful to help model the delivery of energy to the renal blood vessels.

FIG. **20** depicts an alternative method, system **9000** and device to ablate the renal nerves **9015** or the nerves leading to the renal nerves at the aorta-renal artery ostium **9010**. The intravascular device **9020** is placed into the aorta **9050** and advanced to the region of the renal arteries **9025**. Energy is applied from the transducer **9020** and focused **9040** (in the case of HIFU, LIFU, ionizing radiation) to the region of the takeoff of the renal arteries **9025** from the aorta **9050**. This intravascular **9030** procedure can be guided using MRI and/or MRI thermometry or it can be guided using fluoroscopy, ultrasound, or MRI. Because the aorta is larger than the renal arteries, the HIFU catheter can be placed into the aorta directly and cooling catheters can be included as well. In addition, in other embodiments, non-focused ultrasound can be applied to the region around the renal ostium or higher in the aorta. Non-focused ultrasound in some embodiments may require cooling of the tissues surrounding the probe using one or more coolants but in some embodiments, the blood of the aorta will take the place of the coolant, by its high flow rate; HIFU, or focused ultrasound, may not need the cooling because the waves are by definition focused from different angles to the region around the aorta. The vena cava and renal veins can also be used as a conduit for the focused ultrasound transducer to deliver energy to the region as well. In one embodiment, the vena cava is accessed and vibratory energy is passed through the walls of the vena cava and renal vein to the renal arteries, around which the nerves to the kidney travel. The veins, having thinner walls, allow energy to pass through more readily.

FIG. **21a-b** depicts an eyeball **9100**. Also depicted are the zonules of the eye **9130** (the muscles which control lens shape) and ultrasound transducer **9120**. The transducer **9120** applies focused ultrasound energy to the region surrounding the zonules, or the zonules themselves, in order to tighten them such that a presbyopic patient can accommodate and visualize object up close. Similarly, heat or vibration applied to the ciliary muscles, which then increases the outflow of aqueous humor at the region of interest so that the pressure within the eye cannot build up to a high level. The ultrasound transducer **9120** can also be utilized to deliver drug therapy to the region of the lens **9150**, ciliary body, zonules, intra-vitreous cavity, anterior cavity **9140**, posterior cavity, etc.

In some embodiments (FIG. **21b**), multiple transducers **9160** are utilized to treat tissues deep within the eye; the ultrasonic transducers **9170** are focused on the particular region of the eye from multiple directions so that tissues along the path of the ultrasound are not damaged by the ultrasound and the focus region and region of effect **9180** is the position where the waves meet in the eye. In one embodiment, the transducers are directed through the pars plana region of the eye to target the macula **9180** at the posterior pole **9175** of the eye. This configuration might allow for heat, vibratory stimulation, drug delivery, gene delivery, augmentation of laser or ionizing radiation therapy, etc. In certain embodiments, focused ultrasound is not required and generic vibratory waves are transmitted through the eye at frequencies from 20 kHz to 10 MHz. Such energy may be utilized to break up clots in, for example, retinal venous or arterial occlusions which are creating ischemia in the retina. This energy can be utilized in combination with drugs utilized specifically for breaking up clots in the veins of the retina.

FIG. **22** depicts a peripheral joint **9200** being treated with heat and/or vibrational energy. Ultrasound transducer **9210** emits waves toward the knee joint to block nerves **9260** just

42

underneath the bone periosteum **9220** or underneath the cartilage. Although a knee joint is depicted, it should be understood that many joints can be treated including small joints in the hand, intervertebral joints, the hip, the ankle, the wrist, and the shoulder. Unfocused or focused ultrasonic energy can be applied to the joint region to inhibit nerve function reversibly or irreversibly. Such inhibition of nerve function can be utilized to treat arthritis, post-operative pain, tendonitis, tumor pain, etc. In one preferred embodiment, vibratory energy can be utilized rather than heat. Vibratory energy applied to the joint nerves can inhibit their functioning such that the pain fibers are inhibited.

FIG. **23a-b** depicts closure of a fallopian tube **9300** of a uterus **9320** using externally applied ultrasound **9310** so as to prevent pregnancy. MRI or preferably ultrasound can be utilized for the imaging modality. Thermometry can be utilized as well so as to see the true ablation zone in real time. The fallopian tube **9300** can be visualized using ultrasound, MRI, CT scan or a laparoscope. Once the fallopian tube is targeted, external energy **9310**, for example, ultrasound, can be utilized to close the fallopian tube to prevent pregnancy. When heat is applied to the fallopian tube, the collagen in the walls are heated and will swell, the walls then contacting one another and closing the fallopian preventing full ovulation and therefore preventing pregnancy. Although there is no doppler signal in the fallopian tube, the technology for visualization and treatment is similar to that for an artery or other duct. That is, the walls of the tube are identified and modeled, then focused ultrasound is applied through the skin to the fallopian tube to apply heat to the walls of the lumen of the fallopian tube.

In FIG. **23b**, a method is depicted in which the fallopian tubes are visualized **9340** using MRI, CT, or ultrasound. HIFU **9350** is applied under visualization with MRI or ultrasound. As the fallopian tubes are heated, the collagen in the wall is heated until the walls of the fallopian tube close off. At this point the patient is sterilized **9360**. During the treating time, it may be required to determine how effective the heating is progressing. If additional heat is required, then additional HIFU may be added to the fallopian tubes until there is closure of the tube and the patient is sterilized **9360**. Such is one of the advantages of the external approach in which multiple treatments can be applied to the patient, each treatment closing the fallopian tubes further, the degree of success then assessed after each treatment. A further treatment can then be applied **9370**.

In other embodiments, ultrasound is applied to the uterus or fallopian tubes to aid in pregnancy by improving the receptivity of the sperm and/or egg for one another. This augmentation of conception can be applied to the sperm and egg outside of the womb as well, for example, in a test tube in the case of extra-uterine fertilization.

FIG. **24** depicts a feedback algorithm to treat the nerves of the autonomic nervous system. It is important that there be an assessment of the response to the treatment afterward. Therefore, in a first step, modulation of the renal nerves **9400** is accomplished by any or several of the embodiments discussed above. An assessment **9410** then ensues, the assessment determining the degree of treatment effect engendered; if a complete or satisfactory response is determined **9420**, then treatment is completed. For example, the assessment **9410** might include determination through microneurography, assessment of the carotid sinus reactivity (described above), heart rate variability, measurement of norepinephrine levels, etc. With a satisfactory autonomic response, further treatment might not ensue or depending on the degree of response, additional treatments of the nerves **9430** may ensue.

FIG. 25 depicts a reconstruction of a patient from CT scan images showing the position of the kidneys 9520 looking through the skin of a patient 9500. The ribs 9510 partially cover the kidney but do reveal a window at the inferior pole 9530 of the kidney 9520. Analysis of many of these reconstructions has lead to clinical paradigm in which the ribs 9510, pelvis 9420, and the vertebra 9440 are identified on a patient, the kidneys are identified via ultrasound and then renal arteries are identified via Doppler ultrasound.

As shown in FIG. 26a, once the ribs and vertebra are identified with the Doppler ultrasound, an external energy source 9600 can be applied to the region. Specifically, focused ultrasound (HIFU or LIFU) can be applied to the region once these structures are identified and a lesion applied to the blood vessels (renal artery and renal nerve) 9620 leading to the kidney 9610. As described herein, the position of the ultrasound transducer 9600 is optimized on the posterior of the patient as shown in FIG. 26A. That is, with the vertebra, the ribs, and the iliac crest bordering the region where ultrasound is applied.

Based on the data above and specifically the CT scan anatomic information in FIG. 26A, FIG. 26B depicts a device and system 9650 designed for treatment of this region (blood vessels in the hilum of the kidney) in a patient. It contains a 0.5-3 Mhz ultrasound imaging transducer 9675 in its center and a cutout or attachment location of the ultrasound ceramic (e.g. PZT) for the diagnostic ultrasound placement. It also contains a movement mechanism 9660 to control the therapeutic transducer 9670. The diagnostic ultrasound device 9675 is coupled to the therapeutic device in a well-defined, known relationship. The relationship can be defined through rigid or semi-rigid coupling or it can be defined by electrical coupling such as through infrared, optical-mechanical coupling and/or electro-mechanical coupling. Along the edges of the outer rim of the device, smaller transducers 9670 can be placed which roughly identify tissues through which the ultrasound travels. For example, simple and inexpensive one or two-dimensional transducers might be used so as to determine the tissues through which the ultrasound passes on its way to the target can be used for the targeting and safety. From a safety perspective, such data is important so that the ultrasound does not hit bone or bowel and that the transducer is properly placed to target the region around the renal blood vessels. Also included in the system is a cooling system to transfer heat from the transducer to fluid 9662 running through the system. Cooling via this mechanism allows for cooling of the ultrasound transducer as well as the skin beneath the system. A further feature of the system is a sensor mechanism 9665 which is coupled to the system 9650 and records movement of the system 9650 relative to a baseline or a coordinate nearby. In one embodiment, a magnetic sensor is utilized in which the sensor can determine the orientation of the system relative to a magnetic sensor on the system. The sensor 9665 is rigidly coupled to the movement mechanism 9660 and the imaging transducer 9675. In addition to magnetic, the sensor might be optoelectric, acoustic, or radiofrequency based.

Furthermore, the face 9672 of the transducer 9670 is shaped such that it fits within the bony region described and depicted in FIG. 26A. For example, the shape might be elliptical or aspheric or in some cases spheric. In addition, in some embodiments the ultrasound imaging engine might not be directly in the center of the device and in fact might be superior to the center and closer to the superior border of the face and closer to the ribs, wherein the renal artery is visualized better with the imaging probe 9675.

Given the clinical data as well as the devised technologies described above (e.g. FIG. 26A-B), FIG. 27 illustrates the novel treatment plan 9700 to apply energy to the nerves around the renal artery with energy delivered from a position external to the patient.

In one embodiment, the patient is stabilized and/or positioned such that the renal artery and kidneys are optimally located 9710. Diagnostic ultrasound 9730 is applied to the region and optionally, ultrasound is applied from a second direction 9715. The positioning and imaging maneuvers allow the establishment of the location of the renal artery, the hilum, and the vein 9720. A test dose of therapeutic energy 9740 can be applied to the renal hilum region. In some embodiments, temperature 9735 can be measured. This test dose can be considered a full dose if the treatment is in fact effective by one or more measures. These measures might be blood pressure 9770, decrease in sympathetic outflow (as measured by microneurography 9765), increase in parasympathetic outflow, change in the caliber of the blood vessel 9755 or a decrease in the number of spontaneous spikes in a microneurographic analysis in a peripheral nerve (e.g. peroneal nerve) 9765, or an MRI or CT scan which reveals a change in the nervous anatomy 9760. In some embodiments, indices within the kidney are utilized for feedback. For example, the resistive index, a measure of the vasoconstriction in the kidney measured by doppler ultrasound is a useful index related to the renal nerve activity; for example, when there is greater autonomic activity, the resistive index increases, and vice versa.

Completion of the treatment 9745 might occur when the blood pressure reaches a target value 9770. In fact, this might never occur or it may occur only after several years and treatment. The blood pressure might continually be too high and multiple treatments may be applied over a period of years . . . the concept of dose fractionation. Fractionation is a major advantage of applying energy from a region external to a region around the renal arteries in the patient as it is more convenient and less expensive when compared to invasive treatments such as stimulator implantation and interventional procedures such as catheterization of the renal artery.

Another important component is the establishment of the location and position of the renal artery, renal vein, and hilum of the kidney 9720. As discussed above, the utilization of Doppler ultrasound signaling allows for the position of the nerves to be well approximated such that the ultrasound can be applied to the general region of the nerves. The region of the nerves can be seen in FIGS. 29A-D. FIGS. 29A-C are sketches from actual histologic slices. The distances from the arterial wall can be seen at different locations and generally range from 0.3 mm to 10 mm. Nonetheless, these images are from actual renal arteries and nerves and are used so as to develop the treatment plan for the system. For example, once the arterial wall is localized 9730 using the Doppler or other ultrasound signal, a model of the position of the nerves can be established and the energy then targeted to that region to inhibit the activity of the nerves 9720. Notably, the distance of many of these nerves from the wall of the blood vessel indicate that a therapy which applies radiofrequency to the wall of the vessel from the inside of the vessel likely has great difficulty in reaching a majority of the nerves around the blood vessel wall.

FIG. 29D depicts a schematic from a live human ultrasound. As can be seen, the ultrasound travels through skin, through the subcutaneous fat, through the muscle and at least partially through the kidney 8935 to reach the hilum 8941 of the kidney and the renal blood vessels 8937. This direction was optimized through clinical experimentation so as to not

include structures which tend to scatter ultrasound such as bone and lung. Experimentation lead to the optimization of this position for the imaging and therapy of the renal nerves. The position of the ultrasound is between the palpable bony landmarks on the posterior of the patient as described above and below. The vertebrae are medial, the ribs superior and the iliac crest inferior. Importantly, the distance of these structures **8943** is approximately 8-12 cm and not prohibitive from a technical standpoint. These images from the ultrasound are therefore consistent with the results from the CT scans described above as well.

FIG. **29E** depicts the surface area **8760** available to an ultrasound transducer for two patients out of a clinical study. One patient was obese and the other thinner. Quantification of this surface area **8762** was obtained by the following methodology: 1) obtain CT scan; 2) mark off boundary of organs such as the vertebrae, iliac crest, and ribs; 3) draw line from renal blood vessels to the point along the edge of the bone; 4) draw perpendicular from edge bone to the surface of the skin; 5) map the collection of points obtained along the border of the bone. The surface area is the surface area between the points and the maximum diameter is the greatest distance between the bony borders. The collection of points obtained with this method delimits the area on the posterior of the patient which is available to the ultrasound transducer to either visualize or treat the region of the focal spot. By studying a series of patients, the range of surface areas was determined so as to assist in the design which will serve the majority of patients. The transducers modeled in FIG. **30** have surface areas of approximately 11×8 cm or 88 cm² which is well within the surface area shown in FIG. **29E** **8762** which is representative of a patient series. Further more the length, or distance, from the renal artery to the skin was quantified in shortest ray **8764** and longest ray **8766**. Along with the angular data presented above, these data enable design of an appropriate transducer to achieve autonomic modulation and control of blood pressure.

In a separate study, it was shown that these nerves could be inhibited using ultrasound applied externally with the parameters and devices described herein. Pathologic analysis revealed that the nerves around the artery were completely inhibited and degenerated, confirming the ability of the treatment plan to inhibit these nerves and ultimately to treat diseases such as hypertension. Furthermore, utilizing these parameters, did not cause any damage within the path of the ultrasound through the kidney and to the renal hilum.

Importantly, it has also been discovered via clinical trials that when ultrasound is used as the energy applied externally, that centering the diagnostic ultrasound probe such that a cross section of the kidney is visualized and the vessels are visualized, is an important component of delivering the therapy to the correct position along the blood vessels. One of the first steps in the algorithm **9700** is to stabilize the patient in a patient stabilizer custom built to deliver energy to the region of the renal arteries. After stabilization of the patient, diagnostic ultrasound is applied to the region **9730** to establish the extent of the ribs, vertebrae, and pelvis location. Palpation of the bony landmarks also allows for the demarcation of the treatment zone of interest. The external ultrasound system is then placed within these regions so as to avoid bone. Then, by ensuring that a portion of the external energy is delivered across the kidney (for example, using ultrasound for visualization), the possibility of hitting bowel is all but eliminated. The ultrasound image in FIG. **29D** depicts a soft tissue path from outside the patient to the renal hilum inside the patient. The distance is approximately 8-16 cm. Once the patient is positioned, a cushion **9815** is placed

under the patient. In one embodiment, the cushion **9815** is simply a way to prop up the back of the patient. In another embodiment, the cushion **9815** is an expandable device in which expansion of the device is adjustable for the individual patient. The expandable component **9815** allows for compression of the retroperitoneum (where the kidney resides) to slow down or dampen movement of the kidney and maintain its position for treatment with the energy source or ultrasound.

A test dose of energy **9740** can be given to the region of the kidney hilum or renal artery and temperature imaging **9735**, constriction of blood vessels **9755**, CT scans **9760**, microneurography **9765** patch or electrode, and even blood pressure **9770**. Thereafter, the treatment can be completed **9745**. Completion might occur minutes, hours, days, or years later depending on the parameter being measured.

Through experimentation, it has been determined that the region of the renal hilum and kidneys can be stabilized utilizing gravity with local application of force to the region of the abdomen below the ribs and above the renal pelvis. For example, FIGS. **28A-C** depict examples of patient positioners intended to treat the region of the renal blood vessels.

FIG. **28A** is one example of a patient positioned in which the ultrasound diagnostic and therapeutic **9820** is placed underneath the patient. The positioner **9810** is in the form of a tiltable bed. A patient elevator **9815** placed under the patient pushes the renal hilum closer to the skin and can be pushed forward in this manner; as determined in clinical trials, the renal artery is approximately 2-3 cm more superficial in this type of arrangement with a range of approximately 7-15 cm in the patients studied within the clinical trial. The weight of the patient allows for some stabilization of the respiratory motion which would otherwise occur; the patient elevator can be localized to one side or another depending on the region to be treated.

FIG. **28B** detects a more detailed configuration of the ultrasound imaging and therapy engine **9820** inset. A patient interface **9815** is utilized to create a smooth transition for the ultrasound waves to travel through the skin and to the kidneys for treatment. The interface is adjustable such that it is customizable for each patient.

FIG. **28C** depicts another embodiment of a positioner device **9850**, this time meant for the patient to be face down. In this embodiment, the patient is positioned in the prone position lying over the patient elevator **9815**. Again, through clinical experimentation, it was determined that the prone position with the positioner under the patient pushes the renal hilum posterior and stretches out the renal artery and vein allowing them to be more visible to ultrasound and accessible to energy deposition in the region. The positioner underneath the patient might be an expandable bladder with one or more compartments which allows for adjustability in the amount of pressure applied to the underside of the patient. The positioner might also have a back side which is expandable **9825** and can push against the posterior side of the patient toward the expandable front side of the positioner thereby compressing the stretched out renal blood vessels to allow for a more superficial and easier application of the energy device. These data can be seen in FIGS. **7G** and **7H** where the renal artery is quite a bit closer to the skin (7-17 cm down to 6-10 cm). The position of the energy devices for the left side **9827** of the patient and right side **9828** of the patient are depicted in FIG. **28C**. The ribs **9829** delimit the upper region of the device placement and the iliac crest **9831** delimits the lower region of the device placement. The spinous processes **9832** delimit the

medial edge of the region where the device can be placed and the region between **9828** is the location where the therapeutic transducer is placed.

The table elevation is on the front side of the patient, pushing upward toward the renal hilum and kidneys. The head of the table may be dropped or elevated so as to allow specific positioning positions. The elevated portion may contain an inflatable structure which controllably applies pressure to one side or another of the torso, head, or pelvis of the patient.

FIG. **29A-C** depicts the anatomical basis **9900** of the targeting approach described herein. These figures are derived directly from histologic slides. Nerves **9910** can be seen in a position around renal artery **9920**. The range of radial distance from the artery is out to 2 mm and even out to 10 mm. Anatomic correlation with the modeling in FIG. **16B** reveals the feasibility of the targeting and validates the approach based on actual pathology; that is, the approach of applying therapy to the renal nerves by targeting the adventitia of the artery. This is important because the methodology used to target the nerves is one of detecting the Doppler signal from the artery and then targeting the vessel wall around the Doppler signal. Nerves **9910** can be seen surrounding the renal artery **9920** which puts them squarely into the temperature field shown in **16B** indicating the feasibility of the outlined targeting approach in FIG. **27** and the lesion configuration in FIG. **16A**. Further experimentation (utilizing similar types of pathology as well as levels of norepinephrine in the kidney) reveals that the required dose of ultrasound to the region to affect changes in the nerves is on the order of 100 W/cm² for partial inhibition of the nerves and 1-2 kW/cm² for complete inhibition and necrosis of the nerves. These doses or doses in between them might be chosen depending on the degree of nerve inhibition desired in the treatment plan. Importantly, it was further discovered through the experimentation that an acoustic plane through the blood vessels was adequate to partially or completely inhibit the nerves in the region. That is to say, that a plane through which the blood vessels travels perpendicularly is adequate to ablate the nerves around the artery as illustrated in FIG. **16B**. Until this experimentation, there had been no evidence that ultrasound would be able to inhibit nerves surrounding an artery by applying a plane of ultrasound through the blood vessel. Indeed, it was proven that a plane of ultrasound essentially could circumferentially inhibit the nerves around the blood vessel.

FIGS. **30A-I** depict three dimensional simulations from a set of CT scans from the patient model shown in FIG. **26A**. Numerical simulations were performed in three dimensions with actual human anatomy from the CT scans. The same CT scans utilized to produce FIGS. **7E**, **19**, and **25** were utilized to simulate a theoretical treatment of the renal artery region considering the anatomy of a real patient. Utilizing the doses shown in the experimentation above (FIGS. **29A-D**) combined with the human anatomy from the CT scans, it is shown with these simulations that the ability exists to apply therapeutic ultrasound to the renal hilum from a position outside the patient. In combination with FIG. **29**, which as discussed, depicts the position of the nerves around the blood vessels as well as the position of the vessels in an ultrasound, FIG. **30A-I** depicts the feasibility of an ultrasound transducer which is configured to apply the required energy to the region of the hilum of the kidney without damaging intervening structures. These simulations are in fact confirmation for the proof of concept for this therapy and incorporate the knowledge obtained from the pathology, human CT scans, human ultrasound scans, and the system designs presented previously above.

In one embodiment, FIG. **30A**, the maximum intensity is reached at the focus **10010** is approximately 186 W/cm² with a transducer **10000** design at 750 MHz; the transducer is approximately 11×8 cm with a central portion **10050** for an ultrasound imaging engine. The input wattage to the transducer is approximately 120 W-150 W depending on the specific patient anatomy.

FIGS. **30B** and **30C** depict the acoustic focus **10020**, **10030** at a depth of approximately 9-11 cm and in two dimensions. Importantly, the region (tissues such as kidney, ureter, skin, muscle) proximal (**10040** and **10041**) to the focus **10020**, **10030** do not have any significant acoustic power absorption indicating that the treatment can be applied safely to the renal artery region through these tissues as described above. Importantly, the intervening tissues are not injured in this simulation indicating the feasibility of this treatment paradigm.

FIGS. **30D-F** depict a simulation with a transducer **10055** having a frequency of approximately 1 MHz. With this frequency, the focal spot **10070**, **10040**, **10050** size is a bit smaller (approximately 2 cm by 0.5 cm) and the maximum power higher at the focus, approximately 400 W/cm² than shown in FIGS. **30A-C**. In the human simulation, this is close to an optimal response and dictates the design parameters for the externally placed devices. The transducer in this design is a rectangular type of design (spherical with the edges shaved off) so as to optimize the working space in between the posterior ribs of the patient and the superior portion of the iliac crest of the patient. Its size is approximately 11 cm×8 cm which as described above and below is well within the space between the bony landmarks of the back of the patient.

FIGS. **30G-I** depict a simulation with similar ultrasound variables as seen in FIGS. **30D-F**. The difference is that the transducer **10090** was left as spherical with a central cutout rather than rectangular with a central cutout. The spherical transducer setup **10090** allows for a greater concentration of energy at the focus **10075** due to the increased surface area of vibratory energy. Indeed, the maximum energy from this transducer (FIG. **30G**) is approximately 744 W/cm² whereas for the transducer in FIG. **30d**, the maximum intensity is approximately 370 W/cm². FIG. **30H** depicts one plane of the model and **30I** another plane. Focus **10080**, **10085** is depicted with intervening regions **10082** and **10083** free from acoustic power and heat generation, similar to FIG. **30A-F**.

These simulations confirm the feasibility of a therapeutic treatment of the renal sympathetic nerves from the outside without damage to intervening tissues or structures such as bone, bowel, and lung. Hypertension is one clinical application of this therapy. A transducer with an imaging unit within is utilized to apply focused ultrasound to a renal nerve surrounding a renal artery. Both the afferent nerves and efferent nerves are affected by this therapy.

Other transducer configurations are possible. Although a single therapeutic transducer is shown in FIG. **30A-I**, configurations such as phased array therapy transducers (more than one independently controlled therapeutic transducer) are possible. Such transducers allow more specific tailoring to the individual patient. For example, a larger transducer might be utilized with 2, 3, 4 or greater than 4 transducers. Individual transducers might be turned on or off depending on the patient's anatomy. For example, a transducer which would cover a rib in an individual patient might be turned off during the therapy.

Although the central space is shown in the center of the transducer in FIGS. **30A-I**, the imaging transducer might be placed anywhere within the field as long as its position is well known relative to the therapy transducers. For example, insofar as the transducer for therapy is coupled to the imaging

49

transducer spatially in three dimensional space and this relationship is always known, the imaging transducer can be in any orientation relative to the therapeutic transducer.

The invention claimed is:

1. A therapeutic ultrasonic energy system, comprising: 5
a transducer; and
a processor coupled to the transducer;
wherein the processor is configured to control the transducer so that the transducer delivers energy to treatment areas that are arranged approximately in a spherical or ellipsoidal configuration around a reference position associated with a blood vessel.
2. The system of claim 1, wherein the processor is configured to control one or more operation parameter for the transducer so that the transducer delivers the energy to nerve tissue on at least two sides of the blood vessel.
3. The system of claim 1, further comprising an intravascular catheter, wherein the transducer is located on the catheter.
4. The system of claim 3, further comprising a positioning system for determining a position of the intravascular catheter.
5. The system of claim 3, wherein the transducer on the catheter is configured to deliver therapeutic energy.
6. The system of claim 1, wherein the transducer is configured to deliver the energy from outside a patient to inside the patient.
7. The system of claim 1, wherein the transducer is configured to deliver the energy from inside the blood vessel to outside the blood vessel.
8. The system of claim 1, further comprising a motion tracking module to track motion of the blood vessel.
9. The system of claim 8, wherein the motion tracking module is configured to track speckles.
10. The system of claim 8, wherein the motion tracking module is configured to determine a three dimensional coordinate of the blood vessel.
11. The system of claim 8, wherein the motion tracking module is configured to track a doppler ultrasound signal from the blood vessel.
12. The system of claim 1, further comprising a patient interface configured to position the transducer so that regions of bone are avoided by the energy from the transducer.
13. The system of claim 1, wherein the transducer is configured to deliver the energy at an energy level sufficient to create a reduction in a norepinephrine output of an autonomic nerve region.
14. The system of claim 1, wherein the processor is configured to determine a position of the blood vessel, and to control the transducer to deliver the energy to one or more of the treatment areas that are about ten millimeters away from a position of the blood vessel.

50

15. A therapeutic energy system, comprising:
an energy source; and
a processor coupled to the energy source;
wherein the processor is configured to control the energy source so that the energy source delivers energy to treatment areas that are arranged approximately in a spherical or ellipsoidal configuration around a reference position associated with a blood vessel.
16. The system of claim 15, wherein the processor is configured to control one or more operation parameter for the energy source so that the energy source delivers the energy to nerve tissue on at least two sides of the blood vessel.
17. The system of claim 15, further comprising an intravascular catheter, wherein the energy source is located on the catheter.
18. The system of claim 17, further comprising a positioning system for determining a position of the intravascular catheter.
19. The system of claim 17, wherein the energy source on the catheter is configured to deliver therapeutic energy.
20. The system of claim 15, wherein the energy source is configured to deliver the energy from outside a patient to inside the patient.
21. The system of claim 15, wherein the energy source is configured to deliver the energy from inside the blood vessel to outside the blood vessel.
22. The system of claim 15, further comprising a motion tracking module to track motion of the blood vessel.
23. The system of claim 22, wherein the motion tracking module is configured to track speckles.
24. The system of claim 22, wherein the motion tracking module is configured to determine a three dimensional coordinate of the blood vessel.
25. The system of claim 22, wherein the motion tracking module is configured to track a doppler ultrasound signal from the blood vessel.
26. The system of claim 15, further comprising a patient interface configured to position the energy source so that regions of bone are avoided by the energy from the energy source.
27. The system of claim 15, wherein the energy source is configured to deliver the energy at an energy level sufficient to create a reduction in a norepinephrine output of an autonomic nerve region.
28. The system of claim 15, wherein the processor is configured to determine a position of the blood vessel, and to control the energy source to deliver the energy to one or more of the treatment areas that are about ten millimeters away from a position of the blood vessel.
