### **ABSTRACT**

A medical device is provided for use with an endoscope. The medical device can include a tissue resection device comprising an RF cutting wire. The tissue resection device can be supported for proximal and distal movement relative to the endoscope.

# **COMPLETE SPECIFICATION STANDARD PATENT**

Invention Title: **Medical devices for use with endoscope**

**The following statement is a full description of this invention, including  
the best method of performing it known to us:**

## **Medical Devices for Use with Endoscope**

### **Field of the Invention**

The present invention relates to medical devices, and more specifically to a medical device for use in connection with endoscopes and/or endoscopic procedures.

### **Background**

Minimally invasive procedures are desirable because such procedures can reduce pain and provide relatively quick recovery times as compared with conventional open medical procedures. Many minimally invasive procedures are performed with an endoscope (including without limitation laparoscopes). Such procedures permit a physician to position, manipulate, and view medical instruments and accessories inside the patient through a small access opening in the patient's body. Laparoscopy is a term used to describe such an "endosurgical" approach using an endoscope (often a rigid laparoscope). In this type of procedure, accessory devices are often inserted into a patient through trocars placed through the body wall.

Still less invasive treatments include those that are performed through insertion of an endoscope through a natural body orifice to a treatment site. Examples of this approach include, but are not limited to, cystoscopy, hysteroscopy, esophagogastroduodenoscopy, and colonoscopy. Many of these procedures employ the use of a flexible endoscope during the procedure. Flexible endoscopes often have a flexible, steerable section near the distal end that can be controlled by the user by utilizing controls at the proximal end.

Some flexible endoscopes are relatively small (1mm to 3mm in diameter), and may have no integral accessory channel (also called biopsy channels or working channels). Other flexible endoscopes, including gastroscopes and colonoscopes,

have integral working channels having a diameter of about 2.0 to 3.5mm for the purpose of introducing and removing medical devices and other accessory devices to perform diagnosis or therapy within the patient. As a result, the accessory devices used by a physician can be limited in size by the diameter of the accessory channel of the scope used. Additionally, the physician may be limited to a single accessory device when using the standard endoscope having one working channel.

Certain specialized endoscopes are available, such as large working channel endoscopes having a working channel of 5mm in diameter, which can be used to pass relatively large accessories, or to provide capability to suction large blood clots. Other specialized endoscopes include those having two working channels. One disadvantages of such large diameter/multiple working channel endoscopes can be that such devices can be relatively expensive. Further, such large diameter/multiple working channel endoscopes can have an outer diameter that makes the endoscope relatively stiff, or otherwise difficult to intubate.

Various references describe methods or systems that disclose external configurations related to an endoscope, such as for example: US patent 5,025,778, Silverstein; US patent 4,947,827, Opie; US 2002/107530 published August 8, 2002 in the name of Sauer; US patent 6,352,503, Matsui. One disadvantage of known systems is the potential for the distal end of a device used externally of an endoscope to move in a relatively uncontrolled manner, causing the accessory to lack precision or the ability to be maintained within a desired field of view of the imaging capability of the endoscope.

WO 00/48506 published August 24, 2000 in the name of Herrmann discloses a deformable endoscope with at least one supplementary device. The unit comprising the endoscope and the supplementary device is said to have a non-round cross-section. Such a non-circular endoscope may be disadvantageous from the point of view of cost, complexity, or ease in cleaning/sterilization. For instance, a standard endoscope with a smooth, substantially-circular cross section can be relatively easy to sanitize and clean.

WO 00/48506 published August 24, 2000 in the name of Kortenbach, discloses methods and devices for delivering a medical instrument over the exterior of an endoscope to allow the use of instruments too large to fit through the lumena of the endoscope. Kortenbach discloses a collar for use with an endoscope, resilient straps, a flexible sheath having a reclosable seam, flexible polymer extrusions, and a floppy tangential sheath defining a lumen having an irregular (collapsible) cross section. Kortenbach also discloses a track with an inverted T configuration.

#### **Summary of the Invention**

In one embodiment, the present invention provides a tissue resection device which can be used with an endoscope. The tissue resection device includes a tissue receiving opening and an RF tissue cutter, and the device can be positioned proximally and distally relative to the distal end of the endoscope. In another embodiment, the present invention provides a tissue resection device having a tissue receiving opening, and a tissue storage component, such as a sled, slidably supported for movement relative to the opening and for storing tissue samples.

**Brief Description of the Drawings**

FIG. 1 is a cross-section view of a guide system of US Serial Number 10/440,957 filed May 16, 2003 and showing an accessory 50 attached to a mating member 40, with mating member 40 slidably engaging a rail 30, and with rail 30 attached to a flexible attachment flange 25.

Figure 2A is an isometric illustration of an accessory guide 50 and a mating member 40.

Figure 2B is an isometric illustration of a rail 30, flange 25, and a thin walled tube or sheath 27, with flange 25 attached to thin walled tube 27 and flange 25 extending generally radially from thin walled tube 27.

Figure 2C is a cross-sectional illustration showing accessory guide 50 and flange 25 supported in sliding engagement with rail 30, such that accessory guide 50 is spaced radially from thin wall tube or sheath 27.

FIG 3A is a front view of an end cap 55 showing several features including a gripping surface 58 and a guide notch 63.

Figure 3B is a cross section taken at line 3-3 of Figure 3A showing inclination angle 65.

FIG. 4A is an isometric view of the distal end of a guide system 20 in use with an endoscope 100, and showing field of view 110.

Figure 4B is an isometric view of the proximal end of the guide system 20 in combination with an endoscope 100.

FIG. 5A-E show cross section views of various embodiments of a rail 30 and a mating member 40.

FIG. 6 is a cross section view of an embodiment of the guide system 20 according to the present invention showing an attachment means to connect guide system 20 to endoscope 100 through a sheath 80 with an inverted rail 30 disposed within the sheath 80.

FIG 7 is a side view endoscope 100 in a retroflexed curvature, showing rail 30 with a curvature radius R2 different from radius R1 of endoscope 100, and also showing the rail 30 and flange 25 folding or "warping" out of the plane of curvature of the endoscope, and such that rail 30 moves circumferentially relative to endoscope 100.

FIG. 8 is a side view of rail 30 associated with an end cap 55 to direct a non-articulating medical instrument 168 extending from an accessory 50 (in the form of a guide tube 50) into field of view 110 at a convergence point 115 with an instrument 68 extending from an integral channel 93 of endoscope 100.

FIG. 9 shows a side view of an embodiment of guide system 20 without end cap 55 being used with an articulating accessory 71 used to position the distal end of accessory 71 into the field of view 110.

FIG. 10 is an isometric view showing one technique that may be used to direct instrument 168 from accessory 50 into field of view 110 with a snare 73 extending from integral channel 93.

FIG. 11A – C are front views of end cap 55 placed at different orientations on endoscope 100 in order to change the relative position of accessory 50 with respect to integral channel 93 and lens 107 (and location of convergence point 115).

FIG. 12A and 12B are isometric views of one method of using guide system 20 with accessory 50 and instrument 68 to remove a tissue 130 without removing endoscope 100 from its position within the patient.

FIG. 13 shows a cross section view of a proximal end of handle 60 attached to endoscope 100.

FIG. 14 is an isometric view of a distal end of endoscope 100 with rail 30 wrapped around endoscope 100 in a helical arrangement.

FIG. 15 is a cross section view showing a proximal end of endoscope 100 with an arrangement of a second mating member 120 being used to disengage a first device 118 from rail 30.

FIG. 16 is a side view showing a short, relatively straight and relatively rigid device 125 supported on and slid along rail 30 along a section of endoscope 100 curved (such as by retroflexing) to have a radius R3.

Figures 17, 17A, 18, 19, 20, 20A, and 21-38 illustrate various embodiments of the present invention.

#### **Detailed Description of the Invention**

The present invention is a guide system to facilitate introduction of medical accessories into the body of a patient. By way of example, the present invention is illustrated and described for application in flexible endoscopy in a colon of a human patient. However, the present invention is applicable for use in other medical settings, including but not limited to, rigid endoscopy, laparoscopy, cystoscopy, hysteroscopy, esophagogastrroduodenoscopy, sigmoidoscopy, proctoscopy, or enteroscopy in which the body lumens of humans or other mammals are accessed.

By way of reference, Figures 1-16 illustrate devices disclosed in US Serial Number 10/440,957 filed May 16, 2003.

FIG.1 shows a cross section of one embodiment of a guide system 20 shown in US Serial Number 10/440,957 filed May 16, 2003. In Figure 1, guide system 20 is illustrated as generally comprising a track in the form of guide rail 30, a mating member 40, and an accessory 50. In the embodiment shown in Figure 1, accessory 50 can be in the form of a flexible tubular guide for receiving and guiding a medical instrument alongside an endoscope. Guide system 20 can be used to facilitate introduction of accessory 50 into the body of a patient by providing a means to slide accessory 50 along the length of another medical instrument, such as an endoscope, in a controlled manner. Rail 30 may be flexibly supported in spaced relationship from the outer surface of the endoscope by a flexible web in the form of flange 25. Flange 25 can have a thickness  $t$  of between about 0.005 inch and about 0.030 inch, and a height  $h$  of between about 0.020 inch and 1.0 inch. In one embodiment, height  $h$  can be between about 0.080 inch and about 0.200 inch, such as in applications related to the use of colonoscopes in colonoscopy. Flange 25 can be formed of a flexible material, such as a flexible plastic material. One suitable material from which flange 25 can be formed is a thermoplastic elastomer, such as a material designated commercially as Telcar 1025-75 (available from Teknor-Apex, Pawtucket, RI). Height  $h$  provides standoff of accessory 50 from the outside surface of the endoscope. Height  $h$  can be selected to be greater than or equal to about one half the outer diameter of the endoscope with which the guide system 20 is used. Without being limited by theory, such a height  $h$  may provide the advantage that upon bending/flexing of the endoscope 100, such a height  $h$  of the flange 25 can permit the rail 30 to move into approximate alignment with the neutral axis of bending of the endoscope, so that rail 30 does not significantly increase the bending stiffness of the endoscope 100.

Mating member 40 is operatively coupled to rail 30 through interlocking contours. A first contour 140 of mating member 40 can have a substantially matching shape to a second contour 132 of rail 30, so that mating member 40 slides along rail 30. There is a nominal clearance distance between the mating surfaces of mating member 40 and rail 30, so that no binding or pinching occurs when sliding one relative to the other. A nominal clearance of 0.005" may be provided to allow sliding of mating member 40 along rail 30 like a drawer in a drawer slide.

One or both of rail 30 and mating member 40 can be made from a flexible, low friction ("slippery"), plastic material, such as polyethylene, Teflon, or polypropylene to provide a low coefficient of friction between the members as they slide relative to one another. Because the length (as measured perpendicular to the plane of Figure 1) of guide system 20 is much longer than the width (measured parallel to a horizontal line in the plane of Figure 1) of the cross section, various components such as rail 30, mating member 40, attachment flange 25, or accessory 50 may be made with an extrusion process, but such a process is not required. Additionally, rail 30 and flange 25 can be formed as a unitary piece, such as by extrusion. Likewise, mating member 40 and accessory 50 can be formed as a unitary piece, or joined by any suitable attachment method. In Figure 1, flange 25 can include an attachment base 24. Attachment base 24 can provide releasable attachment of the flange 25 to the outer surface of an endoscope. For instance, attachment base 24 can include an adhesive layer on a bottom surface 23, by which flange 25 can be attached to an endoscope. Flange 25 may also be secured to endoscope with adhesive sprays or tapes, Velcro-like attachment materials, non-adhesive silicone tape, with segments of heat shrink tubing, or other suitable attachment means. Such attachments enable rail 30 to be attached to numerous sizes of standard endoscope, allowing guide system 20 to be compatible with standard equipment already owned by a user.

Figures 2A-2C illustrate another embodiment of a guide system 20. Figures 2A is an isometric view of the accessory 50 and mating member 40 of a guide system 20. Figure 2B is an isometric view of the rail 30 and attachment flange 25 associated with a thin wall tube 27. Figure 2C is cross-sectional view of an assembled guide system 20, including accessory guide 50, mating member 40, rail 30, flange 25, and thin walled tube 27, which can be in the form of a flexible sheath.

In Figure 2B and Figure 2C, the attachment flange 25 can be attached to, or be integrally formed with (such as by extrusion) the thin wall tube 27. Thin wall tube 27 is flexible, and can be sized to slide over an endoscope. The guide system 20 can have a continuous, uninterrupted length which is substantially the same as the insertion length (length that is meant to go inside the patient) of an endoscope 100. Alternatively, the guide system can have an overall length that is greater than

the insertion length of the endoscope 100. In one embodiment, the thin walled tube 27, the flange 25, and the rail 30 can have a continuous, uninterrupted length of at least about 50 centimeters, more particularly at least about 100 cm, and still more particularly at least about 160 cm, such as for work associated with a colonoscope and colonoscopy.

The inner diameter of the thin wall tube 27 can be sized to be slightly greater than the outer diameter of the endoscope 100. Endoscope 100, disposed in the thin wall tube 27, can rotate relative to the tube 27, such as when endoscope 100 is retroflexed or otherwise bent or curved. Such relative rotation of the tube 27 (and so flange 25 and rail 30) with respect to the endoscope can assist in the rail 30 being capable of moving circumferentially relative to endoscope 100 and taking on a position that is approximately aligned with the neutral axis of bending of the endoscope.

The thin walled tube 27 and attachment flange 25 shown in Figure 2B and 2C may be made from a flexible plastic, such as thermoplastic elastomer, one example of which is Telcar 1025-75 (Teknor-Apex, Pawtucket, RI). The wall thickness of the thin walled tube 27 and attachment flange 25 may be about 0.0020". Although connected to attachment flange 25, rail 30 may be made from a different material, such as polypropylene, which may be used for providing ease of sliding. One suitable polypropylene is Pro-fax 7823 (Basell, Wilmington, DE). A coextrusion process may be used to form an integral extruded part from at least two different materials, such as with one embodiment of rail 30 and attachment flange 25.

Likewise, similar materials and processes may be used to create accessory 50 attached to mating member 40. For embodiments wherein accessory 50 is in the form of a flexible guide tube, accessory 50 can be made from thermoplastic elastomer, such as Telcar 1025-75 (available from Teknor-Apex of Pawtucket, RI). Mating member 40 can be made from a "slippery" low friction material, such as Teflon, polyethylene, or Pro-fax 7823 polypropylene (available from Basell Co. of Wilmington, DE). Mating member 40 and accessory 50 may be formed through a coextrusion process, or alternatively, may be joined together by any other suitable joining technique.

In use, the rail 30 can be supported on the endoscope prior to insertion of the endoscope into the patient (such as by sliding the thin wall tube or sheath 27 and rail

30 over the endoscope prior to insertion into the patient). Once endoscope 100 is in a position within the body, mating member 40 can be engaged with rail 30, and the mating member 40 and the accessory 50 can then be advanced along the length of the endoscope by sliding engagement with rail 30, so that accessory 50 is positioned in or near a field of view 110 (see FIG. 4A) to perform treatment or diagnosis (such as by advancing a medical instrument through accessory 50).

In the embodiments shown in Figures 1 and 2A-2C, the guide system 20 couples rail 30 to endoscope during a procedure, but does not substantially stiffen the endoscope, and is removable after the procedure without altering or disassembling endoscope. The embodiments shown in Figure 1 and Figures 2A-C permit the rail and associated accessory guide 50 to be attached to various sizes of standard endoscopes, allowing guide system 20 to be compatible with standard endoscopes already owned by the user, and avoiding the need to purchase additional new specialized capital equipment. Rail 30 can be disposable so that after a single patient use, it can be removed from the Endoscope and discarded with other medical waste. Disposability avoids the requirements for cleaning, which could be difficult and time consuming considering the shape of rail 30 which may incorporate a long narrow groove. Mating member 40 and accessory 50 may also be disposable.

In the embodiments shown, the guide system 20 couples rail 30 and the associated accessory 50 to the endoscope such that flexibility and maneuverability of the endoscope is maintained. By way of example, but without limitation, the guide system can be used with a colonoscope without appreciably changing the stiffness of the colonoscope and without appreciably changing the colonoscopes bending axis, due at least in part to the ability of the rail 30 to take on a curved path different from that of the curved endoscope, and the ability of rail 30 to take on a position that is approximately aligned with the neutral axis of bending of the endoscope. Accordingly, the guide system can obviate the need to employ a specialized endoscope having a non-circular cross section, or a cross section that is otherwise modified, such as to provide preferential bending or to accommodate the use of accessories along the side of the endoscope.

Referring to Figures 2A-2C, guide system 20 can have a mating member 40 and a rail 30 either or both of which is substantially the same length as, or longer than the endoscope with which they are used. Such a configuration allows a user to

slide accessory 50 (and any instruments inserted through accessory 50) into a patient's body without relying upon axial stiffness of accessory 50 (or the axial stiffness of the instrument inserted through accessory guide 50). Without being limited by theory, it is believed that mating member 40 and accessory guide 50 can be advanced along rail 30, even though both are flexible, due at least in part to the close clearance between rail 30 and mating member 40 and the continuous, uninterrupted nature of the track provided by rail 30. The embodiments shown permit the insertion of a soft flexible accessory 50, a short accessory 50 that may not inherently possess the rigidity to push it along the side of endoscope 100, or the insertion of a short rigid segment.

Guide system 20 also allows for introduction of a short, rigid device 125, as shown in FIG. 16. For example, a commercially available probe such as the BRAVO™ brand pH Monitoring System available from Medtronics of Minneapolis, MN has a relatively short (approx 25 mm), relatively rigid segment. The pH monitoring system is a wireless capsule which is attached to the wall of the esophagus for approximately 48 hours, during which data is transmitted to a remote (external to patient) receiver. The guide system can be used to deploy the pH monitoring capsule, such as by pushing the capsule through the accessory 50 to the location at which the capsule is to be attached, or by attaching the capsule to the mating member 40 and pushing the capsule by advancing mating member 40 along the length of the endoscope. Alternatively, the rail 30 can have a cross-section that is sized and shaped to permit the device to slide axially along the length of rail 30, while preventing the device from disengaging from the rail.

Flexible flange 25 provides the advantage that a relatively rigid device, (such as for example a generally straight, relatively rigid device) can be pushed by sliding along rail 30, even as the flexible endoscope is retroflexed or otherwise curved. The flexibility of the guide system 20 decouples bending of rail 30 from bending of the endoscope, so that a relatively stiff device or accessory, that would otherwise be difficult to slide to the distal end of the endoscope, can be slid along the curved endoscope. Figure 16 illustrates schematically a relatively rigid device 125 being advanced on rail 30 around a curved segment of endoscope 100.

In another embodiment, accessory 50 can be a device having a length shorter than that of endoscope 100, and not form a working channel. For example, the

accessory 50 could be in the form of a hemostatic gauze pad. The gauze pad could be attached to the distal end of the mating member 40, such as by suture, adhesive, staples, or a clip. The gauze could then be used to treat a bleeding site, after which the gauze pad could be pulled from the body by pulling mating member 40 backward (proximally) along the rail 30. The guide system 20 enables one to push a member that is relatively short and/or has low axial stiffness. The guide system 20 allows advancement of such devices into a patient at least in part because mating member 40 can provide the axial support and the length needed to move such a device into a patient.

Embodiments of the guide system 20 having a mating member 40 with a length that is greater than or substantially equal to the length of rail 30 and the insertion length of the endoscope provide an advantage over endoscopic systems using an engaging member that is not substantially the same length as a track. In such endoscopic systems, a medical instrument to which the engaging member is attached will generally require sufficient axial rigidity to enable pushing of the medical device along the endoscope. Additionally, such endoscopic systems can require a block or "stop" at a distal end of a surface track so that an engaging member is not advanced off the end of the track. In contrast, the embodiments of the guide system 20 having a mating member 40 with a length greater than or substantially equal to that of the rail 30 and the insertion length of the endoscope do not require such a block feature, and provide the advantage that accessory 50 can be advanced beyond the end of the endoscope into a field of view of the endoscope, and then retracted.

Figures 3A and 3B and Figures 4A and 4B illustrate an end cap 55. Figure 3A is an end view of the end cap 55, and Figure 3B is a cross-sectional view taken along section line 3-3 in Figure 3A. End cap 55 can be a component of a guide system 20, or alternatively, end cap 55 can be a separate, stand alone accessory. End cap 55 can be configured to be releasably attachable to the distal end of an endoscope 100. By releasably attachable it is meant that end cap 55 can be repeatedly attached to, and removed from, the endscope without damaging either the end cap 55 or endoscope. End caps 55 can be provided in various sizes to fit onto the ends of various diameter endoscopes. End cap 55 can receive the distal end of

rail 30, and can help control and guide accessory 50 in a field of view 110 (see FIG. 4A) of endoscope 100.

Figure 3B shows a cross-section of the junction of the thin wall flexible tube 27, flexible attachment flange 25, and rail 30 to end cap 55. The junction may be accomplished by adhesive joining or any other suitable joining method. A distal portion of the rail 30 can extend and be held by the notch 63 so that the mating member 40 can slide along the outside surface of end cap 55 in a continuous, non-interrupted path.

End Cap 55 can include a relatively rigid external body, and a relatively soft internal insert 56 with a through bore 57. The insert can include a gripping surface 58. Insert 56 and gripping surface 58 can be provided for releasably attaching end cap 55 to endoscope 100, such that end cap 55 is pushed onto the distal end of endoscope 100 without the need for special tools or assembly techniques to attach or remove end cap 55 to the end of the endoscope. The insert and gripping surface 58 may be made from a sticky or tacky material such as silicone or neoprene, or may include adhesive to hold end cap 55 in place on the distal end of the endoscope 100. Alternatively, end cap 55 can be held in place using a snap fit, an interference fit, or any other suitable attachment means which permits end cap 55 to be releasably attached to the distal end of an endoscope. The remainder of the body of end cap 55 including the external body may be made from a biocompatible plastic, such as nylon 6/6, polycarbonate, or polyvinyl chloride (PVC).

End cap 55 can be provided with smooth rounded edges on its external surface, and connects to a distal portion of endoscope 100. The end cap 55 includes a surface feature on its external surface adapted to guide a medical instrument, such as a medical instrument advanced externally along the endoscope (such as in an accessory guide tube 50). The surface feature can be in the form of a slot, such as guide notch 63. Guide notch 63 can be shaped to receive the distal end of rail 30. The distal end of rail 30 can extend into guide notch 63 (Figure 4A), and the distal end of rail 30 can take on a path determined by the geometry (slope or incline) of guide notch 63, so that the distal end of mating member 40 sliding on rail 30 can follow a path determined by the geometry of guide notch 63. In the embodiment shown, the guide notch 63 is inclined radially inward from the proximal end of the guide notch to the distal end of the guide notch.

In the embodiment shown, guide notch 63 is inclined with respect to the axis of through bore 57 (and so inclined with respect to the longitudinal axis of the endoscope to which end cap 55 is attached). The angle at which guide notch 63 is inclined is indicated by reference numeral 65 to direct accessory 50 into field of view 110. This feature of end cap 55 may be useful to provide convergence of accessory 50 inserted using guide system 20 to an instrument 68 inserted through an integral channel 93 (FIG. 6) of endoscope 100. Depending on the value of angle 65, location of a convergence point 115 (Figure 8) may change. In one embodiment, angle 65 may be at least about 5 degrees, and more particularly at least about 10 degrees. In one embodiment, the angle 65 can have a value between about 10 degrees and about 30 degrees.

In an alternative embodiment to end cap 55, the flange 25 can be tapered, such as by being tapered radially inwardly (e.g. with the flange height  $h$  being reduced at the distal end of the flange 25), so that rail 30 on flange 25 is directed radially inwardly at the distal end of the guide system 20 to guide the accessory 50 both axially and radially inwardly at the distal end of the endoscope 100.

FIG. 4A and 4B illustrate distal and proximal ends of guide system 20 attached to endoscope 100. FIG. 4A shows a distal end of guide system 20 with end cap 55, attachment flange 25, thin wall tubular sheath 27, mating member 40, rail 30, and endoscope 100 (extending through bore 57 of end cap 55). In the embodiment shown, accessory 50 is in the form of an external working channel 52. Working channel 52 can receive and guide a variety of medical instruments from a point outside the patient to a position distal of the distal end of the endoscope within the patient.

As shown in FIG. 4A, the leading (distal) end of mating member 40 can have a tapered or an inclined edge 41 shaped to allow atraumatic passage along endoscope 100 inside a patient's body. The interface between rail 30 and mating member 40 can be located to avoid pinching tissue as the mating member 40 slides in rail 30, such as by locating the interface below an outer surface 144 of rail 30. A smooth covering or a tapered nose on the leading edge of accessory 50 can be employed.

FIG. 4B shows one embodiment of a proximal portion of guide system 20, including flexible tubular sheath 27, attachment flange 25, rail 30, and a hollow

handle 60. Handle 60 includes a through bore for receiving an endoscope such that the endoscope can pass through handle 60. Handle 60 may be constructed of a soft tacky material, such as neoprene or silicone, and may include a slot 36 formed in handle 60 for receiving the proximal end of rail 30. A funnel feature 37 at the proximal end of slot 36 can be employed to facilitate insertion of mating member 40 into rail 30. Handle 60 may be designed to slide over the distal end of an endoscope 100, and can have an internal conical shaped surface to fit against a proximal portion of endoscope 100, near an introductory port 105 integral to endoscope 100, as shown in Figure 4B. Introductory port 105 of endoscope 100 receives medical instruments, such as medical instrument 68 shown in Figure 8. The handle 60 can be permanently fixed to the proximal end of thin wall flexible tube/sheath 27, or alternatively, can be releasably joined to the thin wall tube/sheath 27.

Figure 13 shows a cross section of the junction of the thin walled tube 27, rail 30, and attachment flange 25 to the handle 60. The connection of the tube 27, rail 30, and flange 25 to handle 60 can be permanent, such by use of adhesive. The subassembly comprising the handle 60, thin walled tube 27, rail 30, flange 25, and end cap 55 can be disposable, and can releasably engage the endoscope at one or more locations. For instance, end cap 55 can releasably engage the endoscope 100 at a distal end of the endoscope 100, and handle 60 can releasably engage the endoscope 100 at a proximal portion of the endoscope 100, as shown in Figure 13. In Figure 13, handle 60 can have an inwardly facing conical surface that engages an outwardly facing conical surface on endoscope 100.

FIG. 5A-5D show illustrative, non-limiting embodiments of cross sectional shapes of rail 30 and mating member 40 that allow sliding engagement of rail 30 and mating member 40. It will be understood that rail 30 and mating member 40 may take on various shapes and configurations, such that mating member 40 interlocks with the shape of rail 30 to allow sliding of mating member 40 along rail 30. As viewed in cross section, rail 30 can have opposing arms 31 which maintain engagement of mating member 40 with rail 30. Arms 31, together with the body of rail 30, can define a rail cavity 33 in which the mating member 40 can slide. If desired, arms 31 can be provided with a desired level of resilience, such as by

material choice or dimensioning, so that mating member 40 can be caused to disengage from rail 30 (e.g. by “unzipping” from rail 30), such as if mating member 40 is urged radially outwardly from rail cavity 33. In an alternate embodiment, not shown, a wire may be employed as a rail 30 to provide a path along endoscope 100. Such a wire path may be attached at a distal and proximal end of endoscope 100, and provide a low-profile guide for accessory 50 to follow along endoscope 100.

The embodiment shown in FIG. 5D incorporates accessory 50 (in the form of a circular working channel) within mating member 40. This embodiment could enable the passage of accessories within a lumen of mating member 40 that slides inside rail 30. For example, rail 30 may have a substantially triangular recessed cross section that interlocks with mating member 40 having an outer contour of a triangular shape; and a medical device can slide within a lumen 42 located within mating member 40. This particular embodiment may be suitable for atraumatic passage of mating member 40 along rail 30, and when passing standard size accessories with guide system 20.

In yet another embodiment, mating member 40 can be sized and shaped to fit within rail cavity 33, and not extend above rail 30. In yet another embodiment, as an alternative to (or variation in) the combination of mating member 40 and accessory 50, a guide wire or guide tube having a generally circular cross-section could be disposed in rail cavity 33 for sliding engagement with rail 30. The guide wire or guide tube could have a diameter sized, relative to the size of rail cavity 33 and rail arms 31, such that the guide wire or guide tube can slide in rail cavity 33, while being maintained from disengaging from rail cavity 33 by rail arms 31.

FIG. 6 illustrates an alternate embodiment of attachment flange 25 to those shown in FIG. 1 and FIG. 2 for connecting rail 30 to endoscope 100. A sheath 80 surrounds endoscope 100 and rail 30. Rail 30 can be joined to an inner surface of sheath 80. Such an embodiment allows passage of mating member 40 and accessory 50 within sheath 80, providing for atraumatic passage along the tissue surface.

FIG. 7 shows a side view of rail 30 attached to endoscope 100 with one embodiment of attachment flange 25, showing how endoscope 100 and rail 30 are

able to take on different curvatures, including different curved paths in different planes. The guide system 20 provides support of the rail with respect to the endoscope 100 in a manner that decouples bending of rail 30 and flange 25 from bending of endoscope 100. Accordingly, guide system 20 does not prevent flexing of the endoscope 100. Commercially available flexible endoscopes 100 have the ability to retroflex (bend back to look upon itself) at its distal end. FIG. 7 illustrates this retroflex ability, and how rail 30 with attachment flange 25 is able to take on a path and radius of curvature that is different from the path and radius of curvature of the endoscope. Rail 30 can take on a radius of curvature that is some places (along the length of the endoscope 100) greater than, and in some places less than, the corresponding radius of curvature of the endoscope 100. Without being limited by theory, it is believed that the flexibility of the flange 25 and rail 30 permit the flange 25 and rail 30 to deform out of the plane of curvature of the endoscope to take on a path that reduces the elastic strain that would otherwise be present in the flange 25 and rail 30. In particular, the flexible flange 25 can permit the rail 30 to move into general or approximate alignment with the neutral axis of bending of the endoscope. Accordingly, the rail 30 is not fixed in an o'clock position relative to the endoscope that requires the rail 30 to be subject to tension or compression upon bending of the endoscope (as could be the case if the rail 30 were fixed at a certain circumferential position with respect to the cross section of the endoscope). This arrangement permits the operator to retroflex the endoscope 100, and therefore allows a user to use a normal technique to maneuver the endoscope 100 through the lumen.

By way of example, and without being limited by theory, one may consider bending of endoscope 100 with respect to bending a beam. In beam bending, there is a neutral axis (generally in the center of the beam for symmetric beam cross sections), with one beam surface being in compression, the opposite surface being in tension. A rail supported on an endoscope in such a manner that the rail is subject to tensile stress or compressive stresses upon bending of the endoscope may impede bending of endoscope 100 because of the rail's resistance to tension and/or compression.

The illustration in FIG. 7 shows how a flexible attachment flange 25 can minimize the affect of rail 30 on endoscope 100 bending. The height of attachment flange 25 effectively tethers rail 30 to endoscope 100, but allows rail 30 to find a

path of different curvature and/or move circumferentially with respect to the endoscope. In compression, attachment flange 25 permits rail 30 pleat or otherwise deform (such as in a wavy fashion), minimizing the effect on endoscope 100 bending. In embodiments including a flexible thin wall tube/sheath 27, the decoupling of bending of the rail from bending of the endoscope can be further enhanced due to the ability to accommodate circumferential movement of the tube or sheath 27 with respect to the endoscope.

FIG. 8 illustrates how end cap 55 may be used to hold a distal end of rail 30 to endoscope 100 and present accessory 50 or instrument 168 into field of view 110. Guide system 20 provides a convergence point 115 for a medical instrument 168 extending from an accessory 50 (in the form of an external guide channel in Figure 8) and an instrument 68 extending from an integral working channel 93 of endoscope 100. This feature allows accessory 50 and instrument 168 to be used in conjunction with instrument 68 to perform multiple-handed therapy or diagnosis, such that instrument 168 and instrument 68 are not required to have separate articulation capabilities. In contrast, an endoscope configuration that does not provide the guided convergence (such as at point 115) would typically require one or more instruments to have an articulation feature or other mechanism for providing curvature at the instrument's distal end if it is desired to have one instrument cooperate with another in the endoscope's field of view.

Referring to Figure 9, if the guided convergence of end cap 55 is not provided, cooperation of multiple instruments (such as at convergence point 115) in field of view 110 would require one of instruments (such as instrument 77 in Figure 9) to have a built in articulation capability. End cap 55 with angle 65 allows a user to use standard, non-articulating, accessories or instruments to achieve new therapies or diagnoses.

FIG. 10 illustrates a method of articulating an instrument (such as instrument 168 extending from accessory 50) with a snare 73 extending from integral channel 93 of endoscope 100. The snare 73 can be in the form of a looped wire, and can be advanced from channel 93 to meet an instrument 168 extending from accessory 50. Once the instrument 168 extends through the loop in snare 73, the curvature of

instrument 168 can be increased by advancing instrument 168 from accessory 50, and/or by retracting snare 73 in channel 93. Accordingly, the instrument 168 can be positioned at a desired site (such as a tissue site on the wall of the GI tract).

Figures 11A-C illustrate an additional advantage of use of the end cap 55. Figures 11A-C illustrate the end cap 55 positioned at various o'clock positions on the distal end of endoscope 100. End cap 55 can be positioned on the endoscope 100 so that accessory 50 is located in a desired o'clock position with respect to one or more features of the endoscope, such as integral working channel 93 or optics/viewing lens 107. For instance, in some applications it may be desirable to have the integral channel 93 positioned at a certain distance with respect to accessory 50 to perform a procedure, while in other applications it may be desirable to position the viewing lens 107 at a particular position relative to accessory 50 to obtain a desired field of view.

Figures 12A and 12B illustrate an alternative embodiment in which guide system 20 comprises an adhesive-backed elastically extensible rail, the elastically extensible rail designated by numeral 32 in Figures 12A and 12B. Elastically extensible rail 32 can be formed of a suitable elastically extensible material, so that rail 32 elongates in tension and folds, buckles, or otherwise bends in compression when endoscope is bent or otherwise flexed during use. Rail 32 accommodates bending of the endoscope without substantially altering the bending stiffness of the endoscope. A suitable material for rail 32 is Santoprene Thermoplastic Rubber (Advanced Elastomer Systems, Akron, OH), and a suitable flexible adhesive for attaching rail 30 directly to the outside surface of the endoscope is Super 77 Spray adhesive (3M, St. Paul, MN). Such an embodiment allows rail 32 to change in length or otherwise deform as endoscope 100 is bent, and may be used in embodiments where a flexible flange 25 is not provided.

In Figures 12A and 12B, a tissue mass is shown being captured and severed by a snare 73 extending from a working channel of the endoscope, and grasped by an instrument 168, such as a flexible forceps. The flexible forceps extends through accessory 50 (which is in the form of a flexible guide tube in Figure 12A), and the

flexible forceps can then be used to withdraw the severed tissue mass from the gastro-intestinal tract through the accessory 50.

FIG. 12 A and 12B show one of numerous treatment methods that may be enabled by guide system 20. Removal of multiple biopsies of a tissue 130, such as large polyps currently requires removal of endoscope 100 with the tissue sample 130. This can be time consuming, especially if the physician needs to re-introduce the endoscope 100 through a tortuous colon. FIG. 12A and 12B illustrates how guide system 20 would provide a way to remove such an incised polyp without removing the endoscope 100.

Figure 13 is a cross section view of a proximal end of guide system 20, including a cross section of the attachment of handle 60 to endoscope 100. One component of handle 60 is a guide bar 76 that can be provided (such as by attachment to handle 60) to prevent unintentional disengagement of mating member 40 from rail 30. Mating member 40 can be fed between the guide bar 76 and the body of handle 60 into funnel feature 37. Guide bar 76 can prevent mating member 40 from being inadvertently "peeled" out of or "unzipped" from rail 30 at its proximal end.

In use, a distal end of endoscope 100 can be inserted through the bore in handle 60, through sheath 27, and into the bore of end cap 55. Releasable connections of handle 60 and end cap 55 to endoscope 100 may then be made to hold guide system 20 in place during a procedure. The inner diameter of sheath 27 is preferably sized to allow insertion of endoscope 100 without the need for a lubricant between endoscope 100 and sheath 27. To achieve this, a nominal clearance of at least about 0.040" may be provided between the diameter of endoscope 100 and the inner diameter of sheath 27.

The endoscope 100 with rail 30 can then inserted into the body of a patient. When desired, the physician can then introduce mating member 40 into a funnel feature 37 and slide accessory 50 with mating member 40 along rail 30 into the body of a patient. Accessory 50 may be a working channel, through which instrument 168 may be introduced. The physician can then extend instrument 168 into a field of view 110 to perform a procedure.

While accessory 50 has been described primarily as an additional working channel, it will be understood that accessory 50 can take other forms. Other devices which can be provided as suitable accessories include, but are not limited to, a biopsy forceps, an articulating instrument, a surgical scissor, a device adapted for sewing or stapling tissue, a guidewire, a device adapted for liquid or gas injection, or a tissue ablation system. For instance, various medical instruments could be modified to include a mating member configured to fit and slide in rail 30 (e.g. such as by permanently or non-permanently attaching a mating member 40 to the instrument). Or, alternatively, the rail cavity 33 and rail arms 31 can be sized and shaped to accept a particular medical instrument for sliding engagement in rail cavity 33.

Additionally, a plurality of endoscopes 100 can be connected to each other using guide system 20 by attaching rail 30 to one "parent" endoscope 100, and attaching mating member 40 to a second "daughter" endoscope. Such an arrangement would allow the scopes to be connected and slide relative to each other, providing multiple perspectives of an object within the body of a patient.

Those skilled in the art will also recognize that a plurality of rails 30 may be attached to endoscope 100 to provide multiple paths for instruments to be fed along the outside of endoscope 100. The plurality of rails 30 may be attached to a plurality of attachment flanges 25 or to a common attachment flange 25.

Figure 14 illustrates an embodiment of a guide system 20 wherein rail 30 is wound in a generally helical fashion about an endoscope 100. For instance, the distal end of rail 30 can be joined to the distal end of an endoscope 100, the rail 30 can be wound in a helical manner and in a proximal direction along the endoscopes length, with a proximal end of the rail 30 being joined to a proximal portion of the endoscope. In Figure 14, the distal end of rail 30 is shown associated with an end cap 55. In one embodiment, a guide system 20 can comprise a handle 60, an end cap 55, and a rail 30 extending intermediate the handle 60 and the end cap 55, in which embodiment the flange 25 and flexible tube 27 may be omitted if desired. The end cap 55 can be attached to the distal end of the endoscope, and the rail 30 can be wound loosely about endoscope 100 (or extended in a generally linear fashion along

the endoscope 100 with sufficient slack in rail 30 to allow rail 30 to accommodate bending of the endoscope).

FIG. 15 is a cross section view showing a proximal end of a guide system 20 attached to endoscope 100. One method of using guide system 20 may be to introduce a first device 118 into the body of a patient by intentionally disengaging first device 118 from rail 30 with a second mating member 120. This can be achieved by first introducing first device 118 into rail 30, then disengaging a proximal end of first device 118 from rail 30 (e.g. by pulling the proximal end of first device 118 upward in the plane of Figure 15 to disengage the proximal end of first device 118 from the rail 30), and then introducing the second mating member 120 into sliding engagement with the rail, so that second mating member 120 is disposed between the first device 118 and rail 30 to effectively "unzip" first device 118 from rail 30 as second mating member 120 is advanced distally down the length of rail 30.

For example, first device 118 may be a guidewire, a feeding tube (e.g. to be placed in the esophageal lumen to extend from the oral cavity to the stomach), a duct for conveying a liquid or gas, or any other instrument that is meant to be positioned within a body lumen for temporary or permanent placement. The rail 30 can be positioned within the body lumen, such as by being associated with an endoscope which is introduced into the body lumen. The first device can be introduced onto rail 30 and advanced distally along the rail into a predetermined position within the body. A proximal end of the device 118 can then be disengaged from the rail, as shown in Figure 15. The second mating member 120 can then be introduced under guide bar 76 and into engagement with the rail 30, and advanced axially along the rail in a distal direction to force the device 118 out of engagement with the rail 30, thereby leaving device 118 in place in the body lumen. Advancing second mating member 120 along the rail 30, wherein member 120 is interposed between rail 30 and device 118, causes the device 118 to be urged out of the rail 30 and deployed in a direction generally perpendicular to the rail 30. As shown in Figure 15, member 120 can have a tapered distal end to enhance the ability of member 120 to be interposed between rail 30 and device 118 for urging device 118 out of engagement with rail 30.

Referring again to Figure 16, the guide system 20 can provide advancement and positioning of a relatively rigid and straight device 125 along a curved portion of an endoscope 100. In Figure 16, the device 125 can be pushed by or carried on a mating member 40. The portion of the track 30 on which device 125 is positioned can be relatively straight, in comparison with the corresponding portion of the endoscope which is curved

Referring now to Figure 17, 17A, 18, and 19, in one embodiment of the present invention, a guide system 20 can be used to slidably support a tissue resection device 200 with respect to endoscope 100. Tissue resection device 200 can be used for endoscopic mucosal resection. The guide system 20 allows tissue resection device 200 to be supported with respect to the endoscope 100 such that resection device 200 can be advanced beyond the distal end of the endoscope 100, and moved proximally and distally relative to the distal end of the endoscope to provide a desired view of the device 200 with the imaging capabilities of the endoscope 100.

Alternatively, the tissue resection device 200 can be slidably supported on a track of the type disclosed in above referenced patent applications: "Medical Instrument having a Guidewire and an Add-to Catheter" (Attorney Docket END-5335USNP5) filed May 12, 2005 in the name of Long et al.; and "Improved Track for Medical Devices" (Attorney Docket END-5119CIP1) filed May 13, 2005 in the name of Stefanchik et al.

Tissue resection device 200 can include body 210 having a tissue receiving compartment 220 which opens on an upper surface of body 210. Tissue compartment 220 has a floor 222 and can be generally closed on five sides. Tissue compartment 220 can be generally flat in profile, with a width and length that are each greater than the depth of the compartment 220.

Vacuum can be provided to the tissue receiving compartment 220 via a vacuum line 230. Vacuum line 230 can be supported by the guide system 20 for sliding movement relative to the endoscope 100. Vacuum line 230 provides vacuum to compartment 220 for assisting in drawing tissue into compartment 220. Accordingly, tissue resection device 200 can have a dedicated vacuum line (separate from the endoscope 100). Tissue resection device 200 includes an RF cutting wire

240, which can be connected to a source of RF energy (not shown) outside the body. Cutting wire 240 can be slidably disposed within a wire sleeve 241, and sleeve 241 can be supported with vacuum line 230 by guide system 20. Figure 17A is a schematic cross-section illustrating vacuum line 230 and wire sleeve 241 supported with guide system 20.

Figures 18 and 19 illustrate how cutting wire 240 is adapted to move in compartment 220. Figure 18 shows the wire 240 in a position wherein tissue can enter compartment 220. Wire 240 can include a first end (not shown in Figure 18) located outside the body, and a second end 242. Second end 242 can be fixed to the tissue resection device 200, such as by being fixed to the body 210. When the first end of the wire 240 is pulled proximally (as illustrated by the arrow in Figure 19), the wire 240 is drawn across the opening in compartment 220 to cut the tissue extending into the compartment 220. The wire 240 can include insulation covering selected portions of the wire 240. For example, those portions of the wire 240 which are drawn outside the body 210 as the wire 240 is pulled proximally can be provided with an insulating cover. By way of example, the portion of the wire 240 indicated by numeral 245 in Figure 19 can be free of insulation so that the portion indicated by numeral 245 would provide RF energy to tissue being cut. The second end 242 of wire 240 can be connected electrically by a wire or conductor (not shown) to the generator providing RF energy so as to complete the RF circuit.

Body 210 can include a vacuum line extension 232 (shown in phantom) molded or otherwise formed in body 210, and which communicates vacuum to compartment 220 intermediate the floor 222 and the plane of motion of wire 240.

The cutting wire 240 can be flexible to take on the curvature in the compartment 220. In one embodiment, the wire 240 can comprise a braided, stainless steel conductor and have a diameter of about 0.020 inch. The braided construction of the conductor provides a rough surface, allowing for improved cutting of tissue upon initial contact of the exposed, non-insulated portion of the wire against the tissue. By providing one end of the wire 240 to be fixed (e.g. fixed to body 210), an effective sawing motion can be employed for improved cutting. Further, because one end is fixed, only one end of the wire need be manipulated to provide a sawing motion, thereby providing for simple operation.

Figure 20 illustrates a handle 270 which can be employed for control of vacuum and the RF cutting wire 240. Handle 270 can be operated with a single hand, and can include a button actuator 272 for controlling vacuum in line 230 and a lever actuator 274 for retracting cutting wire 240 proximally/advancing cutting wire 240 distally. A handle capable of being operated with a single hand is disclosed in US Patent Application Serial Number 10/674,186 September 29, 2003, which application is incorporated herein by reference. Handle 270 can receive an RF energy input 275 which is in communication with an RF energy generator (not shown). Handle 270 can also receive a vacuum line input 277 which communicates with a vacuum pump or other source of vacuum (not shown). Vacuum line 230 and sleeve 241 can extend from handle 270 and Vacuum line 230 and/or 241 can include a mating member 40 for engagement with a rail attachment flange 25 associated with a thin wall tube or sheath 27 in which endoscope 100 is received.

Figure 20A illustrates an inflatable component for providing adjustment of the angle at which the device 200 is advanced distally of the endoscope. In Figure 20A, the thin wall flexible tube 27 through which the endoscope 100 passes can include an inflatable component 290. Inflatable component 290 can be used in place of the component 55 in Figure 17. Inflatable component 290 can be a pocket or bladder integral with or separate from the thin wall tube 27, and can be positioned just proximal of the distal end of the tube 27. Inflatable component 290 can be inflated by any suitable means, such as by an inflation line 292 communicating with a source of air or other inflation fluid (gas or liquid) outside the body. The inflatable component can be disposed intermediate the tube 27 and the flange 25, and can be selectively inflated to provide the desired amount of slope (relative to the longitudinal axis of the endoscope) at the distal end of the flange 25, so that device 200 can be positioned in the desired portion of the field of view of the imaging device in the distal end of endoscope 100.

Figure 21 illustrates a tissue resection device 300 which includes a body 310, a tissue receiving compartment 320, a vacuum line 330, and a cutting wire 340 having wire portions 342 and 344 carried within sleeves 341. Wire portions 342 and 344 extend proximally from the body 310 and are supported, with line 330, by guide system 20 for sliding motion relative to the endoscope 100. Cutting wire 340 includes a non-insulated cutting portion 345 which directs RF energy to tissue

received in compartment 320. An actuator located outside the body (for instance a handle of the type shown in Figure 20) can be used to proximally retract/distally advance wire portions 342 and 344 to cut tissue drawn into compartment 320 by vacuum provided through line 330.

Figures 22 and 23 illustrate an embodiment wherein vacuum line 330 and the wire portions 342 and 344 are carried within an accessory sleeve 350. Accessory sleeve 350 can include a mating member 40 for engaging flange 25. Carrying the vacuum line 330 and the RF cutting wire within the sleeve 350 permits rotation of the tissue resection device 300 relative to the endoscope 100 about an axis generally parallel to the longitudinal axis of the endoscope. The rotation is indicated schematically by arrow 301 in Figure 22. Accordingly, tissue resection device 300 is translatable proximally and distally with respect to the distal end of the endoscope and the endoscope optics, and tissue resection device 300 is rotatable with respect to the endoscope about an axis generally parallel to the longitudinal axis of the endoscope.

Figure 24 illustrates tissue resection device 400 comprising a collar 410, and a body portion 415 having tapered side walls and a generally transparent viewing floor 425 (shown partly cut away). The body portion 415 has a tissue receiving compartment 420 disposed beneath viewing floor 425. A vacuum line 430 provides vacuum to compartment 420 through a vacuum port 435 formed in body portion 415. An RF cutting wire 440 is movable in a plane parallel to and just below the opening of compartment 420 to sever tissue drawn within compartment 420.

Collar 410 can be snap fit on the distal end of endoscope 100, and can be formed of any suitable material, including without limitation biocompatible plastics. The vacuum line 430 and cutting wire 440 can be supported along the outside of the endoscope 100, such as by a guide system 20 or any other suitable support system. As endoscope 100 is rotates about its longitudinal axis, the collar 410 and body portion 415 rotate with the endoscope, so that regardless of orientation of the endoscope, the cutting wire and associated tissue to be sampled can be viewed through clear floor 425.

Figure 25 illustrates a tissue resection device 500 comprising a collar 510 for engaging the endoscope 100, such as by snap fit. The device 500 also includes a body portion 515, and a spring or other suitable biasing member 512 disposed

intermediate the collar 510 and a second collar 518 which can be integral with the body portion 515. Second collar 518 is not fastened to the endoscope, but is slidable along the length of at least the distal portion of the endoscope.

The body portion 515 can include a clear viewing floor 525, and a tissue receiving compartment 520 disposed beneath the floor 525 (a portion of the clear floor 525 is shown cut away). An RF cutting wire 540 is positioned in the compartment 520 and supported for movement in a plane parallel to and adjacent the opening to the compartment 520. Vacuum can be provided to the compartment 520 by vacuum line 530.

Spring 512 can be provided to bias the body portion 515 proximally with respect to the endoscope 100. A pull wire 580 can be provided, such as through a channel in the endoscope 100. A first end of the pull wire 580 can be disposed outside the patient's body, and a second end of the pull wire 580 can be fixed to the body 515, such as at a point proximal to the clear viewing floor 525. When tension is applied to pull wire 580, the body 515 is pulled distally with respect to endoscope 100 against the biasing force provided by spring 512. Second collar 518 serves as a bearing support for sliding motion of body 515 with respect to the endoscope 100. Accordingly, by pulling on wire 580, the body 515 and viewing floor 525 can be positioned a desired distance from the distal end of the endoscope 100.

Figures 26 and 27 illustrate a tissue resection device 600 comprising a first collar 610 for engaging the endoscope 100, a second collar 618 adapted to slide along the outer surface of the endoscope 100, a biasing member in the form of a helical coil spring 612 sized to be disposed about the endoscope 100 and disposed intermediate the first collar and the second collar, and a generally cylindrical body 615 (which is illustrated as being transparent in Figure 26) extending distally of the collar 618. An RF cutting wire 640 can extend through and be slidably supported by the second collar 618. The body 615 can include a side tissue receiving opening 660 and a distal end opening 662 through which the distal end of endoscope 100 may pass. Pull wire 680 can have a first end disposed outside the patient's body, and second end fixed to the body 615, such as shown in Figure 27. Pull wire 680 extends through a working channel of endoscope 100 and can be pulled from a point outside the body to advance the body 615 distally with respect to the endoscope 100.

Figure 28 illustrates the body 615 biased proximally by the spring 612 such that the distal end of the body 615 is positioned proximally of the distal end of the endoscope. Figure 29 illustrates how, upon pulling pull wire 680 from a position outside the body, the body 615 is advanced distally over the endoscope.

Vacuum can be provided to the interior of the body 615 through a channel provided in endoscope 100 (or alternatively by a dedicated vacuum line). For example, vacuum can be provided through the channel in which pull wire 680 is disposed, or through a separate channel in the endoscope. Tissue drawn into the body 615 through side opening 660 can be severed by pulling the RF cutting wire proximally across the opening 660, or pushing the RF cutting wire distally across the opening 660, to sever the tissue.

Figures 30-34 illustrate an embodiment of a tissue resection device 600 comprising a tissue sample retrieval system, such as may include a tissue sample bag 700. Tissue sample bag 700 can be disposed, at least in part, in body 615, and can be attached to the interior wall of body 615 by any suitable means, including without limitation by using adhesive. In Figure 30, tissue bag 700 is shown in a deployed state. Tissue bag 700 includes a proximal portion 710 having an opening aligned with the tissue receiving opening 660 in body 615. Tissue bag 700 can also include a distal portion 720. Tissue bag 700 can be formed of any suitable thin, biocompatible film material which is flexible, and which can be folded or rolled as illustrated in the Figures.

Figure 31 illustrates the tissue bag 700 in a closed state, with the distal portion 720 in a rolled, stored configuration in body 615. In Figure 32, as vacuum is applied to the interior of body 615 (such as through a channel in endoscope 100), tissue (indicated by numeral 2000) is drawn into opening 660 and causes the proximal portion 710 to expand to accommodate the tissue. The cutting wire 640 can then be advanced distally (or pulled proximally) to sever tissue drawn into the body 615.

In Figure 33, tissue grasper 3000 can be advanced from a channel of endoscope 100 to grasp the severed tissue sample (or tissue grasper could be used to grasp the tissue prior to severing the sample with wire 640). In Figure 34, the tissue grasper can be used to push or otherwise place the cut tissue sample 2010 distally into the tissue sample bag 700. As multiple samples are added to the bag 700, the

distal portion 720 unrolls or otherwise expands to provide more space for additional samples. Bag 700 can unroll such that distal portion 720 extends distally from end opening. In one embodiment, the device 600 with folded/rolled bag 700 can be advanced distally into the GI tract from the anus to a desired point, such as to the cecum. Samples can be taken first at the most distal point in the GI tract, with each sample being deposited in the sample bag 700. The physician can then move proximally (backwards) in the GI tract to obtain the next sample, and in this fashion work "backwards" from the initial starting point deep inside the GI tract. Because the opening in the tissue bag 700 is aligned with the tissue receiving opening 660, and because the bag 700 unfolds distally of the opening 660, additional samples can be obtained and stored as the doctor moves backward in the GI tract (such as from the cecum to the anal opening), and without obstructing the view of the tissue receiving opening 660 through the endoscope. In particular, the bag 700 can expand/unfold in a distal direction, opposite to the direction in which the doctor is moving the device in the GI tract.

Figures 35-38 illustrate a tissue resection device 800. Device 800 can be disposed at the end of an endoscope 100 or other flexible endoscopic device, such as a flexible corrugated tube for receiving an endoscope. The device 800 can include a body 805, a flexible nose piece 810 extending distally from body 805 having a distal opening, a sled 815 which rides on rails 814 disposed on an upper surface of body 805, and a tissue receiving opening in the top surface of body 805, the tissue receiving opening 816 opening into a vacuum chamber 818. The rails 814 can be disposed in generally parallel relationship on each side of opening 816. A push/pull wire 845 (or other suitable mechanism for advancing/retracting sled) can be employed to advance the sled 815 distally (for obtaining samples) and retract the sled 815 proximally (to expose vacuum chamber 818).

Figure 35 shows the sled retracted so that tissue can be drawn into vacuum chamber 818 and severed using RF cutting wire 840. The sled 815 can then be advanced distally to cover the chamber and severed sample, and the vacuum to chamber 818 can be turned off so that the cut tissue sample may be retained in the sled 815. A gauze material (e.g. such as a gauze pad shown in Figure 37) or other suitable hydrophilic material can be employed on the inside surface of the sled 815 to help retain the cut sample in the sled. Figure 37 illustrates a gauze pad 888

disposed on sled 815 and facing the chamber 818 when the sled is positioned to cover opening 816. Alternatively, the sled 815 can include an apertured, perforated, or textured surface to assist in retaining the sample inside or against the sled.

Figure 37 shows the sled positioned distally and receiving a cut tissue sample. Figure 38 shows the sled retracted proximally of the opening in the vacuum chamber 818 and holding a retained tissue sample.

In use, the sled 815 can be positioned proximally of opening 816, vacuum can be provided to chamber 818 (such as by an endoscope) to draw tissue into chamber 818, and the cutting wire 840 can be used to sever a tissue sample. Vacuum is maintained in chamber 818 as sled 815 is advanced distally. With the sample storage sled 815 in the distal position, the vacuum in chamber 818 is released so the tissue sample can be retained by the gauze or other hydrophilic material disposed in the sled 815. The sled can then be retracted and another sample severed and stored.

While various embodiments of the present invention have been disclosed, it will be obvious to those skilled in the art that such embodiments are provided by way of example only. The present invention may be provided in kit form with other medical devices, including medical devices useful in the working channel of an endoscope, or with an endoscope. The kit elements can be pre-sterilized and packaged in a sealed container or envelope to prevent contamination. The present invention may be provided as a single use disposable device, or alternatively, may be constructed for multiple uses. Further, each element or component of the present invention may be alternatively described as a means for performing the function or functions performed by the element or component. Numerous variations, changes, and substitutions will now occur to those skilled in the art without departing from the invention. Accordingly, it is intended that the invention be limited only by the spirit and scope of the appended claims.

**THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:**

1. An apparatus for use with an endoscope, the apparatus comprising:  
  
a device having a tissue receiving opening and an RF tissue cutting element associated with the tissue receiving opening;  
  
wherein the device is proximally and distally positionable relative to the distal end of the endoscope.
2. The apparatus of Claim 1 comprising a tissue resection device, the tissue resection device being slidably supported with respect to the endoscope.
3. The apparatus of Claim 1 comprising a tissue resection device advancable beyond a distal end of the endoscope.
4. The apparatus of Claim 1 comprising a tissue resection device, wherein the tissue resection device is adapted to be moved proximally and distally relative to a distal end of the endoscope.
5. The apparatus of Claim 1 comprising a tissue resection device having a tissue receiving compartment.
6. The apparatus of Claim 5 wherein the tissue receiving compartment communicates with a source of vacuum separate from the endoscope.
7. The apparatus of Claim 1 comprising a tissue resection device having a body portion, wherein at least a portion of the body portion is transparent.
8. The apparatus of Claim 1 comprising a tissue resection device, and further comprising a member for receiving at least one tissue sample, wherein the member is deployable from a closed state to an open state.

9. The apparatus of Claim 1 comprising a tissue resection device, and further comprising a tissue sample bag adapted to unroll as samples are added to the tissue sample bag.

10. The apparatus of Claim 1 comprising a tissue resection device having a tissue receiving opening, and further comprising a tissue sample bag adapted to unfold in a distal direction as the tissue resection device is moved in a proximal direction.

11. An apparatus for use with an endoscope substantially as hereinbefore described with reference to the accompanying drawings.
