The Sequence Listing filed via EFS-Web is part of the specification and is incorporated in its entirety by reference herein.

BACKGROUND OF THE INVENTION

[0004] Pancreatic enzyme replacement therapy (PERT) finds use in the treatment of pancreatic enzyme insufficiency (PEI). Various disorders, including pancreatitis, cystic fibrosis, celiac disease, inflammatory bowel disease, and pancreatic cancer can lead to PEI, as a consequence of decreased secretion of pancreatic enzymes into the duodenum. This results in poor digestion of food, inadequate absorption of fat, proteins, carbohydrates, and vitamins by the intestines, which can lead to malnutrition. Although orally administered PERT treatments are currently available, the condition may not be alleviated in some people, due to insufficient activity of the PERT in the gastrointestinal tract and/or insufficient patient compliance with the therapy due to the significant pill burden associated with current treatment protocols. In some cases, the coefficient of fat absorption (CFA) and/or coefficient of nitrogen absorption (CNA) is inferior to that of healthy patients, resulting in weight loss and other health concerns. Thus, a need remains in the art for improved PERT treatments.

"Fats" are a subset of lipids composed of fatty acid esters (e.g., triglycerides, which are made from glycerol and three fatty acids). It is not intended that the present invention be limited to any specific lipid and/or fat. Taking the context into consideration, the terms "fat" and "lipid" are used interchangeably herein.

[0059] As used herein, the terms "protein," "polypeptide," and "peptide" are used interchangeably to denote a polymer of at least two amino acids covalently linked by an amide bond, regardless of length or post-translational modification (e.g., glycosylation or phosphorylation).

[0060] As used herein, the term "amino acids" are referred to herein by either their commonly known three-letter symbols or by the one-letter symbols recommended by IUPAC-IUB Biochemical Nomenclature Commission. Nucleotides, likewise, may be referred to by their commonly accepted single letter codes.

[0061] As used herein, the term "engineered," "recombinant," "non-naturally occurring," and "variant," when used with reference to a cell, a polynucleotide or a polypeptide refers to a material or a material corresponding to the natural or native form of the material that has been modified in a manner that would not otherwise exist in nature or is identical thereto but produced or derived from synthetic materials and/or by manipulation using recombinant techniques.

[0062] Recombinant polypeptides can be produced using any suitable methods known the art. Genes encoding the wild-type polypeptide of interest can be cloned in vectors, such as plasmids, and expressed in desired hosts, such as *E. coli, S. cerevisiae,* etc. Variants of recombinant polypeptides can be generated by various methods known in the art. Indeed, there is a wide variety of different mutagenesis techniques well known to those skilled in the art. In addition, mutagenesis kits are also available from many commercial molecular biology suppliers. Methods are available to make specific substitutions at defined amino acids (site-directed), specific or random mutations in a localized region of the gene (regio-specific), or random mutagenesis over the entire gene (*e.g.*, saturation mutagenesis). Numerous suitable methods are known to those in the art to generate

enzyme variants, including but not limited to site-directed mutagenesis of single-stranded DNA or double-stranded DNA using PCR, cassette mutagenesis, gene synthesis, error-prone PCR, shuffling, and chemical saturation mutagenesis, or any other suitable method known in the art. Non-limiting examples of methods used for DNA and protein engineering are provided in the following patents: US Pat. No. 6,117,679; US Pat. No. 6,420,175; US Pat. No. 6,376,246; US Pat. No. 6,586,182; US Pat. No. 7,747,391; US Pat. No. 7,747,393; US Pat. No. 7,783,428; and US Pat. No. 8,383,346. After the variants are produced, they can be screened for any desired property (e.g., high or increased activity, or low or reduced activity, increased thermal activity, increased thermal stability, and/or acidic pH stability, etc.). In some embodiments, "recombinant amylase polypeptides" (also referred to herein as "engineered amylase polypeptides," "variant amylase enzymes," and "amylase variants") find use.

[0063] As used herein, "wild-type" and "naturally-occurring" refer to the form found in nature. For example, a wild-type polypeptide or polynucleotide sequence is a sequence present in an organism that can be isolated from a source in nature and which has not been intentionally modified by human manipulation.

[0064] As used herein, "coding sequence" refers to that part of a nucleic acid (e.g., a gene) that encodes an amino acid sequence of a protein.

[0065] The term "percent (%) sequence identity" is used herein to refer to comparisons among polynucleotides and polypeptides, and are determined by comparing two optimally aligned sequences over a comparison window, wherein the portion of the polynucleotide or polypeptide sequence in the comparison window may comprise additions or deletions (i.e., gaps) as compared to the reference sequence for optimal alignment of the two sequences. The percentage may be calculated by determining the number of positions at which the identical nucleic acid base or amino acid residue occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the window of comparison and multiplying the result by 100 to yield the percentage of sequence identity. Alternatively, the percentage may be calculated by determining the number of positions at which either the identical nucleic acid base or amino acid residue occurs in both sequences or a nucleic acid base or amino acid residue is aligned with a gap to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the window of comparison and multiplying the result by 100 to yield the percentage of sequence identity. Those of skill in the art appreciate that there are many established algorithms available to align two sequences. Optimal alignment of sequences for comparison can be conducted, e.g., by the local homology algorithm of Smith and Waterman (Smith and Waterman, Adv. Appl. Math., 2:482 [1981]), by the homology alignment algorithm of Needleman and Wunsch (Needleman and Wunsch, J. Mol. Biol., 48:443 [1970), by the search for similarity method of Pearson and Lipman (Pearson and Lipman, Proc. Natl. Acad. Sci. USA 85:2444 [1988]), by computerized implementations of these algorithms (e.g., GAP, BESTFIT, FASTA, and TFASTA in the GCG Wisconsin Software

Package), or by visual inspection, as known in the art. Examples of algorithms that are suitable for determining percent sequence identity and sequence similarity include, but are not limited to the BLAST and BLAST 2.0 algorithms, which are described by Altschul et al. (See, Altschul et al., J. Mol. Biol., 215: 403-410 [1990]; and Altschul et al., Nucleic Acids Res., 3389-3402 [1977], respectively). Software for performing BLAST analyses is publicly available through the National Center for Biotechnology Information website. This algorithm involves first identifying high scoring sequence pairs (HSPs) by identifying short words of length W in the query sequence, which either match or satisfy some positive-valued threshold score T when aligned with a word of the same length in a database sequence. T is referred to as, the neighborhood word score threshold (See, Altschul et al., supra). These initial neighborhood word hits act as seeds for initiating searches to find longer HSPs containing them. The word hits are then extended in both directions along each sequence for as far as the cumulative alignment score can be increased. Cumulative scores are calculated using, for nucleotide sequences, the parameters M (reward score for a pair of matching residues; always >0) and N (penalty score for mismatching residues; always <0). For amino acid sequences, a scoring matrix is used to calculate the cumulative score. Extension of the word hits in each direction are halted when: the cumulative alignment score falls off by the quantity X from its maximum achieved value; the cumulative score goes to zero or below, due to the accumulation of one or more negative-scoring residue alignments; or the end of either sequence is reached. The BLAST algorithm parameters W, T, and X determine the sensitivity and speed of the alignment. The BLASTN program (for nucleotide sequences) uses as defaults a wordlength (W) of 11, an expectation (E) of 10, M=5, N=-4, and a comparison of both strands. For amino acid sequences, the BLASTP program uses as defaults a wordlength (W) of 3, an expectation (E) of 10, and the BLOSUM62 scoring matrix (See, Henikoff and Henikoff, Proc. Natl. Acad. Sci. USA 89:10915 [1989]). Exemplary determination of sequence alignment and % sequence identity can employ the BESTFIT or GAP programs in the GCG Wisconsin Software package (Accelrys, Madison WI), using default parameters provided.

[0066] As used herein, "reference sequence" refers to a defined sequence used as a basis for a sequence comparison. A reference sequence may be a subset of a larger sequence, for example, a segment of a full-length gene or polypeptide sequence. Generally, a reference sequence is at least 20 nucleotide or amino acid residues in length, at least 25 residues in length, at least 50 residues in length, at least 100 residues in length or the full length of the nucleic acid or polypeptide. Since two polynucleotides or polypeptides may each (1) comprise a sequence (*i.e.*, a portion of the complete sequence) that is similar between the two sequences, and (2) may further comprise a sequence that is divergent between the two sequences, sequence comparisons between two (or more) polynucleotides or polypeptide are typically performed by comparing sequences of the two polynucleotides or polypeptides over a "comparison window" to identify and compare local regions of sequence similarity. In some embodiments, a "reference sequence" can be based on a primary amino acid

sequence, where the reference sequence is a sequence that can have one or more changes in the primary sequence. "Comparison window" refers to a conceptual segment of at least about 20 contiguous nucleotide positions or amino acids residues wherein a sequence may be compared to a reference sequence of at least 20 contiguous nucleotides or amino acids and wherein the portion of the sequence in the comparison window may comprise additions or deletions (i.e., gaps) of 20 percent or less as compared to the reference sequence (which does not comprise additions or deletions) for optimal alignment of the two sequences. The comparison window can be longer than 20 contiguous residues, and includes, optionally 30, 40, 50, 100, or longer windows.

[0067] "Corresponding to", "reference to" or "relative to" when used in the context of the numbering of a given amino acid or polynucleotide sequence refers to the numbering of the residues of a specified reference sequence when the given amino acid or polynucleotide sequence is compared to the reference sequence. In other words, the residue number or residue position of a given polymer is designated with respect to the reference sequence rather than by the actual numerical position of the residue within the given amino acid or polynucleotide sequence. For example, a given amino acid sequence, such as that of an engineered amylase, can be aligned to a reference sequence by introducing gaps to optimize residue matches between the two sequences. In these cases, although the gaps are present, the numbering of the residue in the given amino acid or polynucleotide sequence is made with respect to the reference sequence to which it has been aligned.

[0068] As used herein, "mutation" refers to any change in a polypeptide or polynucleotide sequence. It is intended to encompass any number (i.e., one or more) of substitutions, insertions, deletions, and/or rearrangements present in a sequence (i.e., as compared to the starting or reference sequence). Thus, mutations in sequences result in the production of variant polypeptides (e.g., variant or recombinant amylases), as provided herein.

[0069] As used herein, "amino acid difference" or "residue difference" refers to a difference in the amino acid residue at a position of a polypeptide sequence relative to the amino acid residue at a corresponding position in a reference sequence. The positions of amino acid differences generally are referred to herein as "Xn," where n refers to the corresponding position in the reference sequence upon which the residue difference is based. For example, a "residue difference at position X92 as compared to SEQ ID NO: 2" refers to a difference of the amino acid residue at the polypeptide position corresponding to position 92 of SEQ ID NO: 2. Thus, if the reference polypeptide of SEQ ID NO: 2 has a threonine at position 92, then a "residue difference at position X92 as compared to SEQ ID NO:2" means there is an amino acid residue other than threonine at the position of the polypeptide corresponding to position 92 of SEQ ID NO: 2 (e.g., T92A). In most instances herein, the specific amino acid residue difference at a position is indicated as "XnY" where "Xn" specified the corresponding position as described above, and "Y" is the single letter identifier of the amino acid found in the engineered polypeptide (i.e., the different residue than in the reference polypeptide). In

some instances (e.g., in Table 4-1, 4-2, 4-3, 4-4, 4-5, 4-6, 4-7, 4-8, 4-9, 4-10, 4-11, 4-12, 4-13, and/or 4-14), the present disclosure also provides specific amino acid differences denoted by the conventional notation "AnB", where A is the single letter identifier of the residue in the reference sequence, "n" is the number of the residue position in the reference sequence, and B is the single letter identifier of the residue substitution in the sequence of the engineered polypeptide. In some instances, a polypeptide of the present disclosure can include one or more amino acid residue differences relative to a reference sequence, which is indicated by a list of the specified positions where residue differences are present relative to the reference sequence. In some embodiments, where more than one amino acid can be used in a specific residue position of a polypeptide, the various amino acid residues that can be used are separated by a "/" (e.g., X446A/X446G/X446M or X446A/G/M or P446A/G/M). In some embodiments, the enzyme variants comprise more than one substitution. These substitutions are separated by a slash for ease in reading (e.g., V408A/M439S). The present application includes engineered polypeptide sequences comprising one or more amino acid differences that include either/or both conservative and non-conservative amino acid substitutions.

[0070] As used herein, "conservative amino acid substitution" refers to a substitution of a residue with a different residue having a similar side chain, and thus typically involves substitution of the amino acid in the polypeptide with amino acids within the same or similar defined class of amino acids. By way of example and not limitation, an amino acid with an aliphatic side chain may be substituted with another aliphatic amino acid (e.g., alanine, valine, leucine, and isoleucine); an amino acid with hydroxyl side chain is substituted with another amino acid with a hydroxyl side chain (e.g., serine and threonine); an amino acids having aromatic side chains is substituted with another amino acid having an aromatic side chain (e.g., phenylalanine, tyrosine, tryptophan, and histidine); an amino acid with a basic side chain is substituted with another amino acid with a basis side chain (e.g., lysine and arginine); an amino acid with an acidic side chain is substituted with another amino acid with an acidic side chain (e.g., aspartic acid or glutamic acid); and/or a hydrophobic or hydrophilic amino acid is replaced with another hydrophobic or hydrophilic amino acid, respectively.

[0071] As used herein, "non-conservative substitution" refers to substitution of an amino acid in the polypeptide with an amino acid with significantly differing side chain properties. Non-conservative substitutions may use amino acids between, rather than within, the defined groups and affects (a) the structure of the peptide backbone in the area of the substitution (e.g., proline for glycine) (b) the charge or hydrophobicity, or (c) the bulk of the side chain. By way of example and not limitation, an exemplary non-conservative substitution can be an acidic amino acid substituted with a basic or aliphatic amino acid; an aromatic amino acid substituted with a small amino acid; and a hydrophilic amino acid substituted with a hydrophobic amino acid.

[0072] As used herein, "deletion" refers to modification to the polypeptide by removal of one or more amino acids from the reference polypeptide. Deletions can comprise removal of 1 or more

amino acids, 2 or more amino acids, 5 or more amino acids, 10 or more amino acids, 15 or more amino acids, or 20 or more amino acids, up to 10% of the total number of amino acids, or up to 20% of the total number of amino acids making up the reference enzyme while retaining enzymatic activity and/or retaining the improved properties of an engineered enzyme. Deletions can be directed to the internal portions and/or terminal portions of the polypeptide. In various embodiments, the deletion can comprise a continuous segment or can be discontinuous.

[0073] As used herein, "insertion" refers to modification to the polypeptide by addition of one or more amino acids from the reference polypeptide. Insertions can be in the internal portions of the polypeptide, or to the carboxy or amino terminus. Insertions as used herein include fusion proteins as is known in the art. The insertion can be a contiguous segment of amino acids or separated by one or more of the amino acids in the naturally occurring polypeptide.

[0074] As used herein, an asterisk (*) used in the context of a polynucleotide sequence indicates the presence of a stop codon within the polynucleotide sequence. In some embodiments, the variant amylases are truncated, as compared to the starting or reference sequence, due to the presence of stop codons.

[0075] A "functional fragment" and a "biologically active fragment" are used interchangeably herein refers to a polypeptide that has an amino-terminal and/or carboxy-terminal deletion(s) and/or internal deletions (e.g., the sequence is truncated), but where the remaining amino acid sequence is identical to the corresponding positions in the sequence to which it is being compared (e.g., a full-length engineered amylase of the present invention) and that retains substantially all of the activity of the full-length polypeptide.

[0076] As used herein, "isolated polypeptide" refers to a polypeptide that is substantially separated from other contaminants that naturally accompany it (e.g., protein, lipids, and polynucleotides). The term embraces polypeptides that have been removed or purified from their naturally-occurring environment or expression system (e.g., host cell or *in vitro* synthesis). The recombinant amylase polypeptides may be present within a cell, present in the cellular medium, or prepared in various forms, such as lysates or isolated preparations. As such, in some embodiments, the recombinant amylase polypeptides can be an isolated polypeptide.

[0077] The terms "isolated" and "purified" are used to refer to a molecule (e.g., an isolated nucleic acid, polypeptide, etc.) or other component that is removed from at least one other component with which it is naturally associated. The term "purified" does not require absolute purity, rather it is intended as a relative definition.

[0078] As used herein, "substantially pure polypeptide" refers to a composition in which the polypeptide species is the predominant species present (i.e., on a molar or weight basis it is more abundant than any other individual macromolecular species in the composition), and is generally a

substantially purified composition when the object species comprises at least about 50 percent of the macromolecular species present by mole or % weight. Generally, a substantially pure amylase composition comprises about 60% or more, about 70% or more, about 80% or more, about 90% or more, about 95% or more, and about 98% or more of all macromolecular species by mole or % weight present in the composition. In some embodiments, the object species is purified from a starting preparation to essential homogeneity (i.e., contaminant species cannot be detected in the composition by conventional detection methods) wherein the composition consists essentially of a single macromolecular species. Solvent species, small molecules (<500 Daltons), and elemental ion species are not considered macromolecular species. In some embodiments, the isolated recombinant amylase polypeptides are substantially pure polypeptide compositions. In some embodiments, substantially pure recombinant amylase polypeptide preparations added to formulations suitable for use in the present invention (e.g., polysaccharides, surfactants, etc.).

[0079] As used herein, an "improved enzyme property" and "improved property" refers to a property of an engineered amylase polypeptide which comprises an improvement in any enzyme property as compared to a reference amylase polypeptide and/or as a wild-type amylase polypeptide or another engineered amylase polypeptide. Improved properties include but are not limited to such properties as increased protein expression, increased thermoactivity, increased thermostability, increased pH activity, increased stability, increased enzymatic activity, increased substrate specificity or affinity, increased specific activity, increased resistance to substrate or end-product inhibition, increased chemical stability, improved chemoselectivity, improved solvent stability, increased tolerance to acidic or basic pH, increased tolerance to proteolytic activity (i.e., reduced sensitivity to proteolysis), reduced aggregation, increased solubility, reduced immunogenicity, improved post-translational modification (e.g., glycosylation), and altered temperature profile.

[0080] As used herein, "increased enzymatic activity" or "enhanced catalytic activity" refers to an improved property of the engineered amylase polypeptides, that can be represented by an increase in specific activity (e.g., product produced/time/weight protein) or an increase in percent conversion of the substrate to the product (e.g., percent conversion of starting amount of substrate to product in a specified time period using a specified amount of amylase) as compared to the reference amylase enzyme. Exemplary methods to determine enzyme activity are provided in the Examples. Any property relating to enzyme activity may be affected, including the classical enzyme properties of K_m, V_{max} or k_{cat}, changes of which can lead to increased enzymatic activity. Improvements in enzyme activity can be from about 1.1 fold the enzymatic activity of the corresponding wild-type enzyme, to as much as 2-fold, 5-fold, 10-fold, 20-fold, 25-fold, 50-fold, 75-fold, 100-fold, 150-fold, 200-fold or more enzymatic activity than the naturally occurring amylase or another engineered amylase from which the amylase polypeptides were derived.

[0081] Amylase activity can be measured by any suitable method known in the art (e.g., standard assays, such as monitoring changes in spectrophotometric properties of reactants or products). In some embodiments, the amount of products produced can be measured by using ethylidene pNP-G7 as a substrate and monitoring the p-nitrophenol released by monitoring absorbance at A405. In some embodiments, starch can be used as the substrate, and the amount of maltose produced can be measured with the dinitrosalicylic acid assay and monitoring absorbance at 540nm, while in some other embodiments, the products can be measured using alternative methods known in the art. Comparisons of enzyme activities are made using a defined preparation of enzyme, a defined assay under a set condition, and one or more defined substrates, as further described in detail herein.

[0082] As used herein, the terms "protease stable" and "stability to proteolysis" refer to the ability of a protein (e.g., a recombinant amylase of the present invention) to function and withstand proteolysis mediated by any proteolytic enzyme or other proteolytic compound or factor and retain its function following treatment with the protease. It is not intended that the term be limited to the use of any particular protease to assess the stability of a protein. Indeed, the engineered amylases of the present invention are stable and retain enzymatic activity in the presence of various proteases. In some embodiments, the recombinant amylases of the present invention to function and withstand proteolysis mediated by any proteolytic enzyme or other proteolytic compound or factor and retain its function following exposure to a protease. In some embodiments, the engineered amylases are stable in the presence of trypsin, chymotrypsin, and/or pepsin. However, it is not intended that the present invention be limited to any specific protease or any particular method of assessing proteolytic stability.

[0083] As used herein, the term "pH stability" refers to the ability of a protein (e.g., a recombinant amylase of the present invention) to function after incubation at a particular pH. In some embodiments, the present invention provides recombinant amylases that are stable at a range of pHs, including, but not limited to the range of pH 2 to pH 7. In some embodiments, the recombinant amylases are stable at different pH ranges, as indicated in the Examples provided herein. It is not intended that the present invention be limited to any pH stability level nor pH range.

[0084] As used herein, the term "improved tolerance to acidic pH" means that a recombinant amylase according to the invention will have increased stability (higher retained activity at about pH 7, 6, 5, 4 3, 2, or even lower, after exposure to acidic pH for a specified period of time [e.g., 1 hour, up to 24 hours, etc.]) as compared to a reference amylase or another enzyme.

[0085] "Physiological pH" as used herein means the pH range generally found in a subject's (e.g., human) blood (e.g., pH 7.2 – 7.4).

[0086] The term "basic pH" (e.g., used with reference to improved stability to basic pH conditions or increased tolerance to basic pH) means a pH range of about 7 to 11, or in some embodiments, greater than pH 11.

[0087] The term "acidic pH" (e.g., used with reference to improved stability to acidic pH conditions or increased tolerance to acidic pH) means a pH range that encompasses any pH values less than 7. In some embodiments, the acid pH is less than 7, while in some other embodiments, the pH is less than about 6, 5, 4, 3, 2, or lower. In some alternative embodiments, the recombinant amylases of the present invention are stable at pH levels of 2 to 4. However, it is not intended that the present invention be limited to any specific pH value or range of values.

[0088] As used herein, the phrase "gastric challenge" refers to the exposure of the recombinant amylases of the present invention to a low pH environment and the presence of at least one enzyme (e.g., pepsin), such that the recombinant amylase is exposed to the conditions that may be encountered in the stomach (e.g., the human stomach).

[0089] As used herein, the phrase "intestinal challenge" refers to the exposure of the recombinant amylases of the present invention to a neutral pH environment and the presence of at least one protease (e.g., intestinal proteases such as trypsin and/or chymotrypsin) and/or at least one bile salt (e.g., sodium taurocholate), such that the recombinant lipase is exposed to the conditions that may be encountered in the intestinal tract (e.g., human intestines).

[0090] As used herein, the phrase "multiple challenges in sequence" refers to the exposure of the recombinant amylases of the present invention to a series of challenge conditions. For example, in some embodiments, a one hour heat challenge was followed by a one hour gastric challenge, and then followed by a one hour intestinal challenge. It is not intended that the present invention be limited to any specific challenges and/or challenge conditions or a specific sequence of challenges.

[0091] The terms "thermal stability" and "thermostability" refer to the ability of a protein (e.g., a recombinant amylase of the present invention) to function at a particular temperature. In some embodiments, the term refers to the ability of a protein to function following incubation at a particular temperature. In some embodiments, the recombinant amylases of the present invention are "thermotolerant" (i.e., the enzymes maintain their catalytic activity at elevated temperatures). In some embodiments, the recombinant amylases resist inactivation at elevated temperatures and in some embodiments, maintain catalytic activity at elevated temperatures for prolonged exposure times. These terms are used interchangeably herein. It is not intended that the present invention be limited to any specific temperature and/or exposure time. Such stability can be measured by any method known in the art (e.g., the methods described herein). It is not intended that the present invention be limited to any specific temperature stability level nor temperature range. In some embodiments, thermal

stability is measured following incubation of a protein (e.g., a recombinant amylase of the present invention) at a particular temperature.

[0092] As used herein, the term "chemical stability" refers to the ability of a protein (e.g., a recombinant amylase of the present invention) to function in the presence of a chemical that adversely affects the function of another protein. It is not intended that the present invention be limited to any specific chemical stability level nor range of chemical stabilities.

[0093] As used herein, the term "conversion" refers to the enzymatic conversion (or biotransformation) of a substrate(s) to the corresponding product(s). "Percent conversion" refers to the percent of the substrate that is converted to the product within a period of time under specified conditions. Thus, the "enzymatic activity" or "activity" of an amylase polypeptide can be expressed as "percent conversion" of the substrate to the product in a specific period of time.

[0094] As used herein, "hybridization stringency" relates to hybridization conditions, such as washing conditions, in the hybridization of nucleic acids. Generally, hybridization reactions are performed under conditions of lower stringency, followed by washes of varying but higher stringency. The term "moderately stringent hybridization" refers to conditions that permit target-DNA to bind a complementary nucleic acid that has about 60% identity, preferably about 75% identity, about 85% identity to the target DNA, with greater than about 90% identity to target-polynucleotide. Exemplary moderately stringent conditions are conditions equivalent to hybridization in 50% formamide, 5× Denhart's solution, 5×SSPE, 0.2% SDS at 42°C, followed by washing in 0.2×SSPE, 0.2% SDS, at 42°C. "High stringency hybridization" refers generally to conditions that are about 10°C or less from the thermal melting temperature T_m as determined under the solution condition for a defined polynucleotide sequence. In some embodiments, a high stringency condition refers to conditions that permit hybridization of only those nucleic acid sequences that form stable hybrids in 0.018M NaCl at 65°C (i.e., if a hybrid is not stable in 0.018M NaCl at 65°C, it will not be stable under high stringency conditions, as contemplated herein). High stringency conditions can be provided, for example, by hybridization in conditions equivalent to 50% formamide, 5× Denhart's solution, 5×SSPE, 0.2% SDS at 42°C, followed by washing in 0.1×SSPE, and 0.1% SDS at 65°C. Another high stringency condition is hybridizing in conditions equivalent to hybridizing in 5X SSC containing 0.1% (w:v) SDS at 65°C and washing in 0.1x SSC containing 0.1% SDS at 65°C. Other high stringency hybridization conditions, as well as moderately stringent conditions, are described in the references cited above.

[0095] As used herein, a "vector" is a DNA construct for introducing a DNA sequence into a cell. In some embodiments, the vector is an expression vector that is operably linked to a suitable control sequence capable of effecting the expression in a suitable host of the polypeptide encoded in the DNA sequence. In some embodiments, plasmids find use as vectors. In some embodiments, an "expression

vector" has a promoter sequence operably linked to the DNA sequence (e.g., transgene) to drive expression in a host cell, and in some embodiments, also comprises a transcription terminator sequence.

[0096] As used herein, "codon optimized" refers to changes in the codons of the polynucleotide encoding a protein to those preferentially used in a particular organism such that the encoded protein is more efficiently expressed in the organism of interest. Although the genetic code is degenerate in that most amino acids are represented by several codons, called "synonyms" or "synonymous" codons, it is well known that codon usage by particular organisms is nonrandom and biased towards particular codon triplets. This codon usage bias may be higher in reference to a given gene, genes of common function or ancestral origin, highly expressed proteins versus low copy number proteins, and the aggregate protein coding regions of an organism's genome. In some embodiments, the polynucleotides encoding the amylase enzymes may be codon optimized for optimal production from the host organism selected for expression.

[0097] As used herein, "control sequence" includes all components that are necessary or advantageous for the expression of a polynucleotide and/or polypeptide of the present application. Each control sequence may be native or foreign to the nucleic acid sequence encoding the polypeptide. Such control sequences include, but are not limited to, a leader, polyadenylation sequence, propeptide sequence, promoter sequence, signal peptide sequence, initiation sequence and transcription terminator. At a minimum, the control sequences include a promoter, and transcriptional and translational stop signals. The control sequences may be provided with linkers for the purpose of introducing specific restriction sites facilitating ligation of the control sequences with the coding region of the nucleic acid sequence encoding a polypeptide.

[0098] As used herein, the term "operably linked" is defined herein as a configuration in which a control sequence is appropriately placed (i.e., in a functional relationship) at a position relative to a polynucleotide of interest such that the control sequence directs or regulates the expression of the polynucleotide and/or polypeptide of interest.

[0099] As used herein, "promoter sequence" refers to a nucleic acid sequence that is recognized by a host cell for expression of a polynucleotide of interest, such as a coding sequence. The promoter sequence contains transcriptional control sequences, which mediate the expression of a polynucleotide of interest. The promoter may be any nucleic acid sequence that shows transcriptional activity in the host cell of choice including mutant, truncated, and hybrid promoters, and may be obtained from genes encoding extracellular or intracellular polypeptides either homologous or heterologous to the host cell.

[0100] As used herein, the phrase "suitable reaction conditions" refers to those conditions in the enzymatic conversion reaction solution (e.g., ranges of enzyme loading, substrate loading,

temperature, pH, buffers, co-solvents, etc.) under which a amylase polypeptide of the present application is capable of converting a substrate to the desired product compound, Exemplary "suitable reaction conditions" are provided in the present application and illustrated by the Examples.

[0101] As used herein, "loading," such as in "compound loading" or "enzyme loading" refers to the concentration or amount of a component in a reaction mixture at the start of the reaction.

[0102] As used herein, the term "substrate" used in the context of an enzymatic conversion reaction process refers to the compound or molecule acted on by the amylase polypeptide.

[0103] As used herein, the term "product" used in the context of an enzymatic conversion process refers to the compound or molecule resulting from the action of the amylase polypeptide on a substrate.

[0104] As used herein, the term "expression" includes any step involved in the production of the polypeptide including, but not limited to, transcription, post-transcriptional modification, translation, and post-translational modification. Polynucleotides Encoding Engineered Polypeptides, Expression Vectors and Host Cells

[0162] The present invention provides polynucleotides encoding the engineered amylase polypeptides described herein. In some embodiments, the polynucleotides are operatively linked to one or more heterologous regulatory sequences that control gene expression to create a recombinant polynucleotide capable of expressing the polypeptide. Expression constructs containing a heterologous polynucleotide encoding the engineered amylase polypeptides can be introduced into appropriate host cells to express the corresponding amylase polypeptide.

[0163] As will be apparent to the skilled artisan, availability of a protein sequence and the knowledge of the codons corresponding to the various amino acids provide a description of all the polynucleotides capable of encoding the subject polypeptides. The degeneracy of the genetic code, where the same amino acids are encoded by alternative or synonymous codons, allows an extremely large number of nucleic acids to be made, all of which encode the engineered amylase polypeptide. Thus, having knowledge of a particular amino acid sequence, those skilled in the art could make any number of different nucleic acids by simply modifying the sequence of one or more codons in a way which does not change the amino acid sequence of the protein. In this regard, the present invention specifically contemplates each and every possible variation of polynucleotides that could be made encoding the polypeptides described herein by selecting combinations based on the possible codon choices, and all such variations are to be considered specifically disclosed for any polypeptide described herein, including the variants provided in Table 4-1, 4-2, 4-3, 4-4, 4-5, 4-6, 4-7, 4-8, 4-9, 4-10, 4-11, 4-12, 4-13, and/or 4-14; and variants provided in Table 4-1, 4-2, 4-3, 4-4, 4-5, 4-6, 4-7, 4-8, 4-9, 4-10, 4-11, 4-12, 4-13, and/or 4-14, where the variants are absent the histidine tag and preceding amino acid linker.

[0164] In various embodiments, the codons are preferably selected to fit the host cell in which the protein is being produced. For example, preferred codons used in bacteria are used for expression in bacteria, while preferred codons used in fungi are used for expression in fungi. Consequently, codon optimized polynucleotides encoding the engineered amylase polypeptides contain preferred codons at about 40%, 50%, 60%, 70%, 80%, or greater than 90% of codon positions of the full length coding region.

[0183] In some embodiments, an isolated polynucleotide encoding any of the engineered amylase polypeptides provided herein is manipulated in a variety of ways to provide for expression of the gene and production of the polypeptide. In some embodiments, the polynucleotides encoding the polypeptides are provided as expression vectors, in which one or more control sequences is present to regulate the expression of the polynucleotides and/or polypeptides. Manipulation of the isolated polynucleotide prior to its insertion into a vector may be desirable or necessary depending on the expression vector. The techniques for modifying polynucleotides and nucleic acid sequences utilizing recombinant DNA methods are well known in the art.

[0184] In some embodiments, the control sequences include among other sequences, promoters, leader sequences, polyadenylation sequences, propeptide sequences, signal peptide sequences, and transcription terminators. [0187] In some embodiments, the control sequence is a suitable transcription terminator sequence, a sequence recognized by a host cell to terminate transcription. The terminator sequence is operably linked to the 3' terminus of the nucleic acid sequence encoding the polypeptide. Any terminator which is functional in the host cell of choice finds use in the present invention. For example, exemplary transcription terminators for bacterial host cells can be obtained from the T7 bacterial phage for the T7 terminator, or *Escherichia coli* ribosomal RNA, for example the rrnB terminator. [0188] In some embodiments, the control sequence is a suitable leader sequence, a non-translated region of an mRNA that is important for translation by the host cell. The leader sequence is operably

linked to the 5' terminus of the nucleic acid sequence encoding the polypeptide. Any leader sequence that is functional in the host cell of choice may be used. Exemplary leaders for filamentous fungal host cells are obtained from the genes for *Aspergillus oryzae* TAKA amylase and *Aspergillus nidulans* triose phosphate isomerase. [0189] In some embodiments, the control sequence may also be a polyadenylation sequence, a sequence operably linked to the 3' terminus of the nucleic acid sequence and which, when transcribed, is recognized by the host cell as a signal to add polyadenosine residues to transcribed mRNA. Any polyadenylation sequence which is functional in the host cell of choice may be used in the present invention. Useful polyadenylation sequences for yeast host cells are also known in the art (See e.g., Guo and Sherman, Mol. Cell. Biol., 15:5983-5990 [1995]).

[0190] In some embodiments, the control sequence is a signal peptide coding region that codes for an amino acid sequence linked to the amino terminus of a polypeptide and directs the encoded polypeptide into the cell's secretory pathway. The 5' end of the coding sequence of the nucleic acid sequence may inherently contain a signal peptide coding region naturally linked in translation reading frame with the segment of the coding region that encodes the secreted polypeptide. Alternatively, the 5' end of the coding sequence may contain a signal peptide coding region that is foreign to the coding sequence.

[0191] Any signal peptide coding region that directs the expressed polypeptide into the secretory pathway of a host cell of choice finds use for expression of the engineered amylase polypeptides provided herein. Effective signal peptide coding regions for filamentous fungal host cells include, but are not limited to the signal peptide coding regions obtained from the genes for *Aspergillus oryzae* TAKA amylase, *Aspergillus niger* neutral amylase, *Aspergillus niger* glucoamylase, *Rhizomucor miehei* aspartic proteinase, *Humicola insolens* cellulase, and *Humicola lanuginosa* protease. Useful signal peptides for yeast host cells include, but are not limited to those from the genes for *Saccharomyces cerevisiae* alpha-factor and *Saccharomyces cerevisiae* invertase. Useful signal peptides for mammalian host cells include but are not limited to those from the genes for immunoglobulin gamma (IgG).

[0192] In some embodiments, the control sequence is a propeptide coding region that codes for an amino acid sequence positioned at the amino terminus of a polypeptide. The resultant polypeptide is

referred to as a "proenzyme," "propolypeptide," or "zymogen," in some cases). A propolypeptide can be converted to a mature active polypeptide by catalytic or autocatalytic cleavage of the propeptide from the propolypeptide.

[0193] In another aspect, the present invention also provides a recombinant expression vector comprising a polynucleotide encoding an engineered amylase polypeptide, and one or more expression regulating regions such as a promoter and a terminator, a replication origin, etc., depending on the type of hosts into which they are to be introduced. in some embodiments, the various nucleic acid and control sequences described above are joined together to produce a recombinant expression vector which includes one or more convenient restriction sites to allow for insertion or substitution of the nucleic acid sequence encoding the variant amylase polypeptide at such sites. Alternatively, the polynucleotide sequence(s) of the present invention are expressed by inserting the polynucleotide sequence or a nucleic acid construct comprising the polynucleotide sequence into an appropriate vector for expression. In creating the expression vector, the coding sequence is located in the vector so that the coding sequence is operably linked with the appropriate control sequences for expression.

[0194] The recombinant expression vector may be any vector (e.g., a plasmid or virus), that can be conveniently subjected to recombinant DNA procedures and can result in the expression of the variant amylase polynucleotide sequence. The choice of the vector will typically depend on the compatibility of the vector with the host cell into which the vector is to be introduced. The vectors may be linear or closed circular plasmids.

[0195] In some embodiments, the expression vector is an autonomously replicating vector (i.e., a vector that exists as an extra-chromosomal entity, the replication of which is independent of chromosomal replication, such as a plasmid, an extra-chromosomal element, a minichromosome, or an artificial chromosome). The vector may contain any means for assuring self-replication. In some alternative embodiments, the vector may be one which, when introduced into the host cell, is integrated into the genome and replicated together with the chromosome(s) into which it has been integrated. Furthermore, a single vector or plasmid or two or more vectors or plasmids which together contain the total DNA to be introduced into the genome of the host cell, or a transposon may be used.

[0196] In some embodiments, the expression vector preferably contains one or more selectable markers, which permit easy selection of transformed cells.

[0197] A "selectable marker" is a gene the product of which provides for biocide or viral resistance, resistance to heavy metals, prototrophy to auxotrophs, and the like. Suitable markers for bacterial host cells include, but are not limited to carbenicillin, ampicillin, chloramphenicol, tetracyclineJD, kanamycin and zeocin.

[0198] Suitable markers for yeast host cells include, but are not limited to ADE2, HIS3, LEU2, LYS2, MET3, TRP1, and URA3. Selectable markers for use in a filamentous fungal host cell include, but are not limited to, amdS (acetamidase), argB (ornithine carbamoyltransferases), bar (phosphinothricin acetyltransferase), hph (hygromycin phosphotransferase), niaD (nitrate reductase), pyrG (orotidine-5'-phosphate decarboxylase), sC (sulfate adenyltransferase), and trpC (anthranilate synthase), as well as equivalents thereof. In another aspect, the present invention provides a host cell comprising a polynucleotide encoding at least one engineered amylase polypeptide of the present application, the polynucleotide being operatively linked to one or more control sequences for expression of the engineered amylase enzyme(s) in the host cell.

[0199] Host cells for use in expressing the polypeptides encoded by the expression vectors of the present invention are well known in the art and include but are not limited to, bacterial cells (e.g., *E. coli*); fungal cells, such as yeast cells (e.g., *Saccharomyces cerevisiae* and *Pichia pastoris* [e.g., ATCC Accession No. 201178]); insect cells (e.g., Drosophila S2 and Spodoptera Sf9 cells), plant cells, animal cells (e.g., CHO, COS, and BHK), and human cells (e.g., HEK293T, human fibroblast, THP-1, Jurkat and Bowes melanoma cell lines).

[0200] Accordingly, in another aspect, the present invention provides methods for producing the engineered amylase polypeptides, where the methods comprise culturing a host cell capable of expressing a polynucleotide encoding the engineered amylase polypeptide under conditions suitable for expression of the polypeptide. In some embodiments, the methods further comprise the steps of isolating and/or purifying the amylase polypeptides, as described herein.

[0201] Appropriate culture media and growth conditions for the above-described host cells are well known in the art. Polynucleotides for expression of the amylase may be introduced into cells by various methods known in the art. Techniques include, among others, electroporation, biolistic particle bombardment, liposome mediated transfection, calcium chloride transfection, and protoplast fusion.

[0202] The engineered amylase with the properties disclosed herein can be obtained by subjecting the polynucleotide encoding the naturally occurring or engineered amylase polypeptide to mutagenesis and/or directed evolution methods known in the art, and as described herein. An exemplary directed evolution technique is mutagenesis and/or DNA shuffling (See e.g., Stemmer, Proc. Natl. Acad. Sci. USA 91:10747-10751 [1994]; WO 95/22625; WO 97/0078; WO 97/35966; WO 98/27230; WO 00/42651; WO 01/75767 and U.S. Pat. 6,537,746). Other directed evolution procedures that can be used include, among others, staggered extension process (StEP), in vitro recombination (See e.g., Zhao et al., Nat. Biotechnol., 16:258–261 [1998]), mutagenic PCR (See e.g., Caldwell et al., PCR Methods Appl., 3:S136-S140 [1994]), and cassette mutagenesis (See e.g., Black et al., Proc. Natl. Acad. Sci. USA 93:3525-3529 [1996]).

[0203] Recombinant polypeptides can be produced using any suitable methods known in the art. Genes encoding the wild-type polypeptide of interest can be cloned in vectors, such as plasmids, and expressed in desired hosts, such as *E. coli,* etc. Variants of recombinant polypeptides can be generated by various methods known in the art. Indeed, there is a wide variety of different mutagenesis techniques well known to those skilled in the art. In addition, mutagenesis kits are also available from many commercial molecular biology suppliers. Methods are available to make specific substitutions at defined amino acids (site-directed), specific or random mutations in a localized region of the gene (regio-specific), or random mutagenesis over the entire gene (e.g., saturation mutagenesis). Numerous suitable methods are known to those in the art to generate enzyme variants, including but not limited to site-directed mutagenesis of single-stranded DNA or double-stranded DNA using PCR, cassette mutagenesis, gene synthesis, error-prone PCR, shuffling, and chemical saturation mutagenesis, or any other suitable method known in the art. Mutagenesis and directed evolution methods can be readily applied to enzyme-encoding polynucleotides to generate variant libraries that can be expressed, screened, and assayed. Any suitable mutagenesis and directed evolution methods find use in the present invention and are well known in the art (See e.g., US Patent Nos. 5,605,793, 5,811,238, 5,830,721, 5,834,252, 5,837,458, 5,928,905, 6,096,548, 6,117,679, 6,132,970, 6,165,793, 6,180,406, 6,251,674, 6,265,201, 6,277,638, 6,287,861, 6,287,862, 6,291,242, 6,297,053, 6,303,344, 6,309,883, 6,319,713, 6,319,714, 6,323,030, 6,326,204, 6,335,160, 6,335,198, 6,344,356, 6,352,859, 6,355,484, 6,358,740, 6,358,742, 6,365,377, 6,365,408, 6,368,861, 6,372,497, 6,337,186, 6,376,246, 6,379,964, 6,387,702, 6,391,552, 6,391,640, 6,395,547, 6,406,855, 6,406,910, 6,413,745, 6,413,774, 6,420,175, 6,423,542, 6,426,224, 6,436,675, 6,444,468, 6,455,253, 6,479,652, 6,482,647, 6,483,011, 6,484,105, 6,489,146, 6,500,617, 6,500,639, 6,506,602, 6,506,603, 6,518,065, 6,519,065, 6,521,453, 6,528,311, 6,537,746, 6,573,098, 6,576,467, 6,579,678, 6,586,182, 6,602,986, 6,605,430, 6,613,514, 6,653,072, 6,686,515, 6,703,240, 6,716,631, 6,825,001, 6,902,922, 6,917,882, 6,946,296, 6,961,664, 6,995,017, 7,024,312, 7,058,515, 7,105,297, 7,148,054, 7,220,566, 7,288,375, 7,384,387, 7,421,347, 7,430,477, 7,462,469, 7,534,564, 7,620,500, 7,620,502, 7,629,170, 7,702,464, 7,747,391, 7,747,393, 7,751,986, 7,776,598, 7,783,428, 7,795,030, 7,853,410, 7,868,138, 7,783,428, 7,873,477, 7,873,499, 7,904,249, 7,957,912, 7,981,614, 8,014,961, 8,029,988, 8,048,674, 8,058,001, 8,076,138, 8,108,150, 8,170,806, 8,224,580, 8,377,681, 8,383,346, 8,457,903, 8,504,498, 8,589,085, 8,762,066, 8,768,871, 8,849,575, 9,593,326, 9,665,694, 9,684,771, 9,864,833, 9,996,661, and all related US, as well as PCT and non-US counterparts; Ling et al., Anal. [0204] In some embodiments, the enzyme variants obtained following mutagenesis treatment are screened by subjecting the enzyme variants to a defined temperature (or other assay conditions) and measuring the amount of enzyme activity remaining after heat treatments or other assay conditions. DNA containing the polynucleotide encoding the amylase polypeptide is then isolated from the host cell, sequenced to identify the nucleotide sequence changes (if any), and used to express the enzyme in a different or the same host cell. Measuring enzyme activity from the expression libraries can be performed using any suitable method known in the art (e.g., standard biochemistry techniques, such as HPLC analysis).

[0205] For engineered polypeptides of known sequence, the polynucleotides encoding the enzyme can be prepared by standard solid-phase methods, according to known synthetic methods. In some embodiments, fragments of up to about 100 bases can be individually synthesized, then joined (e.g., by enzymatic or chemical ligation methods, or polymerase mediated methods) to form any desired continuous sequence. For example, polynucleotides and oligonucleotides disclosed herein can be prepared by chemical synthesis using the classical phosphoramidite method (See e.g., Beaucage et al., Tetra. Lett., 1981, 22:1859-69; and Matthes et al., EMBO J., 1984, 3:801-05), as it is typically practiced in automated synthetic methods. According to the phosphoramidite method, oligonucleotides are synthesized (e.g., in an automatic DNA synthesizer), purified, annealed, ligated and cloned in appropriate vectors. However, it is not intended that the present invention be limited to any specific method for production of polynucleotides and oligonucleotides, as any suitable method finds use in the present invention.

[0206] Accordingly, in some embodiments, a method for preparing the engineered amylase polypeptide can comprise: (a) synthesizing a polynucleotide encoding a polypeptide comprising an amino acid sequence selected from the amino acid sequence of any variant provided in Table 4-1, 4-2, 4-3, 4-4, 4-5, 4-6, 4-7, 4-8, 4-9, 4-10, 4-11, 4-12, 4-13, and/or 4-14; any variant provided in Table 4-1, 4-2, 4-3, 4-4, 4-5, 4-6, 4-7, 4-8, 4-9, 4-10, 4-11, 4-12, 4-13, and/or 4-14, wherein the variant lacks the histidine tag and preceding amino acid linker; as well as SEQ ID NOS: 2, 18, 40, 156, 174, 276, 308, 422, 456, 546, 632, 664, 780, 988, 1104, 1122, 1224, 1256, 1370, 1404, 1494, 1580, 1612, and/or 1728; any of the even numbered polypeptide sequence of SEQ ID NOS: 4-18, 22-966, and 970-1914; and (b) expressing the amylase polypeptide encoded by the polynucleotide. In some embodiments of the method, the amino acid sequence encoded by the polynucleotide comprises one or several (e.g., up to 3, 4, 5, or up to 10) amino acid residue deletions, insertions and/or substitutions. In some further embodiments, the amino acid sequence comprises 1-2, 1-3, 1-4, 1-5, 1-6, 1-7, 1-8, 1-9, 1-10, 1-15, 1-20, 1-21, 1-22, 1-23, 1-24, 1-25, 1-30, 1-35, 1-40, 1-45, or 1-50 amino acid residue deletions,

insertions and/or substitutions. In still some other embodiments, the amino acid sequence comprises 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 30, 31, 32, 33, 34, 35, 40, 45, or 50 amino acid residue deletions, insertions and/or substitutions. In some embodiments, the amino acid sequence comprises 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 18, 20, 21, 22, 23, 24, or 25 amino acid residue deletions, insertions and/or substitutions. In some embodiments, the substitutions are conservative or non-conservative substitutions.

[0207] The expressed engineered amylase polypeptide can be assessed for any desired improved property (e.g., activity, selectivity, stability, acid tolerance, protease sensitivity, etc.), using any suitable assay known in the art, including but not limited to the assays and conditions described herein.

[0208] In some embodiments, any of the engineered amylase polypeptides expressed in a host cell are recovered from the cells and/or the culture medium using any one or more of the well-known techniques for protein purification, including, among others, lysozyme treatment, sonication, filtration, salting-out, heat treatment, ultra-centrifugation, and chromatography.

[0209] Chromatographic techniques for isolation of the amylase polypeptides include, among others, reverse phase chromatography high performance liquid chromatography, ion exchange chromatography, hydrophobic interaction chromatography, gel electrophoresis, and affinity chromatography. Conditions for purifying a particular enzyme depends, in part, on factors such as net charge, hydrophobicity, hydrophilicity, molecular weight, molecular shape, etc., and will be apparent to those having skill in the art. In some embodiments, affinity techniques may be used to isolate the improved variant amylase enzymes. In some embodiments utilizing affinity chromatography purification, any antibody which specifically binds the variant amylase polypeptide finds use.

[0210] In some embodiments utilizing affinity chromatography purification, proteins that bind to the glycans covalently attached to amylase find use. In still other embodiments utilizing affinity-chromatography purifications, any small molecule that binds to the amylase active site finds use. For the production of antibodies, various host animals, including but not limited to rabbits, mice, rats, etc., are immunized by injection with a polypeptide (e.g., a amylase variant), or a fragment thereof. EXAMPLE 1 - Amylase Gene Acquisition and Construction of Expression Vectors

[0223] The DNA sequences encoding bacterial amylases from various organisms listed in **Table 1-1**, were codon-optimized for expression in *E. coli*, and cloned into the *E. coli* expression vector pCK110900 vector system (See e.g., US Pat. Nos. 7,629,157, and 9,714,437, and US Pat. Appln. Publn. 2006/0195947, all of which are hereby incorporated by reference herein). The plasmid construct was transformed into an *E. coli* strain derived from W3110. The *E. coli* strains containing the amylase genes were grown in either 96-well or shake flask format and assayed for amylase activity as described in Example 3. The activity obtained from these amylases are shown in **Table 1-1**.

EXAMPLE 2 - Engineered Amylase Variants Expression and Construction

[0224] Based on the results shown in Table 1-1, the amylase from SEQ ID NO: 2 was subcloned with a C-terminal 6xHis-tag into the pJV110900 vector system (See e.g., US Pat. Appln Publ. 2017/213758, hereby incorporated by reference) to generate SEQ ID NO: 18. However, it is not intended that the present invention be limited to any specific vectors. The plasmid construct was transformed into an *E. coli* strain derived from W3110. Directed evolution techniques generally known by those skilled in the art were used to generate libraries of gene variants from this plasmid construct (See e.g., US Pat. No. 8,383,346, and WO2010/144103) as well as its derivatives.

EXAMPLE 3 - High-Throughput (HTP) Growth of Amylase Variants and Screening Conditions

[0225] Methods used to grow cells producing the amylases of the present invention, as well as screening methods to characterize the amylases are provided in this Example.

High-Throughput (HTP) Growth of *E. coli* Amylase and Variant Amylases

[0226] Transformed *E. coli* cells were selected by plating onto LB agar plates containing 1% glucose with selection. After overnight incubation at 37°C, colonies were placed into the wells of 96-well shallow flat bottom plates (NUNC™, Thermo-Scientific) filled with 180 µl/well LB supplemented with 1% glucose and a selection marker. The cultures were allowed to grow overnight for 18-20 hours in a shaker incubator (200 rpm, 30°C, and 85% relative humidity; Kuhner).

[0227] Overnight growth samples (20 µL) were transferred into COSTAR® 96-well deep plates filled with 380µL of Terrific Broth supplemented with a selection compound (e.g., chloramphenicol). The plates were incubated for 135 minutes in a shaker incubator (250 rpm, 30°C, and 85% relative humidity; Kuhner). The expression of the amylase variants was then induced with 40 µL of 10 mM IPTG in sterile water and the cultures were incubated overnight for 20-24 hours in a shaker incubator (250 rpm, 30°C, and 85% relative humidity; Kuhner). The cells were pelleted by centrifugation (4000 rpm x 20 min), the supernatants were discarded, and the cells were frozen at -80°C prior to analysis.

Lysis of HTP Pellets

[0228] First, 200-400 µL of lysis buffer (1X PBS, 1 mg/ml lysozyme, 0.5 mg/ml polymyxin B sulfate, and .1U/mL DNAse I (NEB) were added to the cell pellets. The cell pellet and buffer were gently shaken for 1.5-2 hours at room temperature, and centrifuged (4000 rpm x 15 min) prior to use of the clarified lysates in the various HTP assays described herein. Analysis of these lysates by SDS-PAGE revealed the presence of an overexpressed protein bands at an apparent MW of 57kDa,

consistent with the expected MW of the amylase of interest. In some additional experiments, additional dilutions of clarified lysate were performed with PBS buffer prior to challenges and analysis.

Analysis of Clarified Lysates or Purified Protein for Amylase Activity

[0229] Amylase activity was assessed using soluble starch as a substrate and quantifying maltose produced from starch hydrolysis using dinitrosalicylic acid (DNSA). Starch solution was prepared by mixing 10 mg/mL potato starch in assay buffer (20 mM sodium phosphate buffer pH 6.9 + 6.7 mM NaCl, or 100 mM $NaPO_4$ pH, 6.0 – 7.0). To dissolve the starch, the solution was heated on a stir plate to near boiling then allowed to cool to room temperature. To create the DNSA solution, 20 ml of 96 mM DNSA in water was added dropwise to 12 ml water and 8 ml 5.3M potassium sodium tartrate tetrahydrate in 2N NaOH with mixing on a hot plate (70-80°C); DNSA solution was cooled to room temperature before use. To set up amylase activity reactions, starch substrate solution was mixed 2:1 with diluted enzyme in a PCR plate (BioRad) and incubated at 37 °C for 30 minutes. The reaction was then mixed 1:1 with the DNSA solution and incubated for 15 minutes at 95 °C in a thermocycler. Samples were diluted 2x in assay buffer and transferred to a UV-STAR® flat bottom plate (Greiner), then read for absorbance at 540nm on a Molecular Devices SPECTRAMAX® M2 plate reader. In some experiments, in order to ensure that samples did not saturate the assay, samples were diluted in PBS buffer prior to analysis, based on a pre-determined dilution factor (up to 512x).

Alternate Method for Analysis of Clarified Lysates or Purified Protein for Amylase Activity

[0230] In some experiments, amylase activity was assessed by using ethylidene pNP-G7 as a substrate and monitoring the p-nitrophenol released by monitoring absorbance at A405. This assay was performed using an Amylase Activity Assay Kit (Sigma). In this assay, 50 ul of challenged, diluted amylase variant were added to 50 ul of provided assay buffer and 50 ul of provided ethylidene pNP-G7 substrate solution. Absorbance at 405nm was monitored for 15 minutes, and absorbance at a representative time point was used for subsequent analysis.

HTP Analysis of Clarified Lysates or Purified Proteins Pre-Treated with Heat Challenge

[0231] To assess the thermostability of the variants, clarified lysate was transferred to a PCR plate (Biorad) and incubated for 1 hr at 40-60°C in a thermocycler. After incubation, samples were centrifuged to pellet heat-precipitated proteins and the supernatant was analyzed for amylase residual activity as described herein.

HTP Analysis of Clarified Lysates or Purified Proteins Pre-Treated with low pH and Pepsin

[0232] The activities of amylase variants were determined after pre-incubation at low pH in the presence of pepsin, to simulate the stomach environment. First, clarified lysate was diluted 0x – 32x in PBS buffer, then mixed 1:1 with McIlvaine buffer, pH 2.3-3.5 + 3.0 mg/mL pepsin from porcine

gastric mucosa (Sigma) in a PCR plate (Biorad), for a final challenge pH of 2.3-3.5 and a final pepsin concentration of 1.5 mg/ml. Samples were mixed and then incubated for 1-2 hrs at 37°C. To stop the challenges, samples were mixed 1:1 with 400 mM $NaPO_4$, pH 7.0, to neutralize the pH and inactivate the pepsin. Neutralized challenge samples were then analyzed for residual amylase activity as described herein.

HTP Evaluation of Amylase Activity After Incubation with Intestinal Proteases

[0233] The activities of variants were determined after pre-incubation at neutral pH in the presence of sodium taurocholate and intestinal proteases, to simulate the intestinal environment. Clarified lysate was mixed 1:1 in a PCR plate (BioRad) with 100 mM $NaPO_4$, pH 7.0, or PBS containing 0-10 mM sodium taurocholate, trypsin from porcine pancreas at 3mg/ml, and chymotrypsin from bovine pancreas at 3 mg/ml, for a final concentration of 0-5 mM sodium taurocholate, and a final concentration of 1.5 mg/ml of each challenging intestinal protease. The mixture was incubated for 1-2 hrs at 37°C, in a thermocycler. Samples were then analyzed for residual amylase activity as described herein.

HTP Evaluation of Amylase Activity After Incubation with Engineered Protease

[0234] The activities of amylase variants were determined after pre-incubation at neutral pH in the presence of an engineered trypsin-like protease (SEQ ID NO: 20). Clarified lysate was mixed 1:1 in a PCR plate (BioRad) with PBS containing 3 mg/ml lyophilized powder of SEQ ID NO: 20, for a final concentration of 1.5 mg/ml protease in the challenge. The mixture was incubated for 1-2 hrs at 37°C, in a thermocycler. Samples were then analyzed for residual amylase activity as described herein.

HTP Evaluation of Amylase Activity After Multiple Sequential Challenges

[0235] When two stability characteristics were simultaneously being investigated, multiple challenge screens were combined in series. For example, in some experiments, a one hour heat challenge was followed by a one hour pH and pepsin challenge, which was then followed by a one hour intestinal challenge. In the instance of an intestinal challenge following a gastric challenge, the challenging intestinal proteases were dissolved in the neutralization buffer for the gastric challenge, so that the intestinal challenge was started immediately upon neutralization of the gastric challenge. This is denoted as a "sequential challenge." Following a sequential challenge, samples were analyzed for residual amylase activity as described herein.

Shake Flask Expression, Purification and Characterization of Amylase Variants

[0236] A single colony of *E. coli* containing a plasmid encoding an engineered amylase was inoculated into 5 mL Luria Bertani media with 1% glucose and a selection marker. Cells were grown overnight (at least 16 hours) in an incubator at 30°C with shaking at 250 rpm. The culture was diluted into 250 mL Terrific Broth (12 g/L bacto-tryptone, 24 g/L yeast extract, 4 mL/L glycerol, 65 mM

potassium phosphate, pH 7, 1 mM $MgSO_4$) with selection, in a 1 liter flask and allowed to grow at 30°C. Expression of the amylase gene was induced by addition of IPTG to a final concentration of 1 mM when the OD600 of the culture reached 0.6 to 0.8. Incubation was then continued overnight (at least 16 hours). Cells were harvested by centrifugation (5000 rpm, 15 min, 4°C) and the supernatant discarded. The cells were resuspended in 40-50 ml of PBS with 150 mM NaCl, and passed through a MICROFLUDIZER® high pressure homogenizer (Microfluidics) with standard *E. coli* lysis settings and maintained at 4°C.

[0237] The cleared lysate supernatant was collected, and imidazole was added to the lysate for a final concentration of 25 mM. This lysate was HIS-affinity purified on the AKTA Start system with the AC Step 1 ml/5 ml HiTrap - Affinity Chromatography Quick Start using the manufacturer's (GE Healthcare) protocol, using PBS with150mL NaCl and 25 mM imidazole as the wash buffer, and PBS with 150 ml NaCl and 250 mM imidazole as the elution buffer. The purified amylase variants were buffer exchanged into PBS with ECONOPAC®-10DG desalting prepacked gravity-flow columns (Biorad).

[0238] The purified amylase variants were assayed for unchallenged activity, gastric stability, intestinal stability in a similar manner as described herein, except that instead of using cell lysates, 1 mg/ml of the purified enzymes were used in the stability experiments.

EXAMPLE 4: Screening Results For Amylase Variants

[0239] Library variants were generated from homolog diversity and saturation mutagenesis on surface positions based on a structural model of SEQ ID NO: 18. These variants were screened in triplicate for amylase activity at pH 6.8, after the sequential challenge of 1 hour incubation at 50°C, followed by a 1 hour gastric challenge (1.5 mg/mL pepsin, pH 3), and finally a 1 hour intestinal challenge for 1 hour, as described in Example 3. The results (relative to the results for SEQ ID NO: 18) are provided in **Table 4-1**.

[0240] Based on the results shown in **Table 4-1**, SEQ ID NO: 40 was chosen as the parent sequence for the next iteration of protein optimization. Beneficial mutations identified from those listed in **Table 4-2** were recombined into this backbone. The variants were assayed in triplicate for amylase activity at pH 6.8 after pre-incubations with two different conditions: a 1 hr incubation at 50°C, followed by a 1 hr intestinal screen, and a one hour incubation at 50°C, followed by a 1 hr gastric challenge at pH 3.5, as described in Example 3. The results (relative to the results for SEQ ID NO: 40) are shown in **Table 4-2**.

[1]Levels of increased activity were determined relative to the reference polypeptide of SEQ ID NO: 40, and defined as follows: "+" > 0.9; "++" > 1.1; "+++" > 2; and "++++" > 3.

[0241] Based on the results shown in **Table 4-2**, SEQ ID NO: 156 was chosen as the parent sequence for the next iteration of protein optimization. Beneficial mutations identified from the results shown in **Table 4-2** were recombined into the backbone. Additionally, to generate new diversity, variants produced with saturation mutagenesis at different positions were also constructed using SEQ ID NO: 156.

[0242] The variants were assayed in triplicate for amylase activity at pH 6.8, after pre-incubation under two different conditions. The first condition was a 1 hour gastric challenge at pH 3.25 and the second condition was a 2 hr gastric challenge at pH 3.25, as described in Example 3. The results (relative to the results for SEQ ID NO: 156) are provided in **Table 4-3**.

[1]Levels of increased activity were determined relative to the reference polypeptide of SEQ ID NO: 174, and defined as follows: "+" > 0.9; "++" > 1.1; and "+++" > 2.			

[0244] Based on the results shown in **Table 4-4**, SEQ ID NO: 276 was chosen as the parent sequence for the next iteration of protein optimization. Beneficial mutations identified based on the results shown in **Table 4-4**, and mutations to revert variant sequences to wild-type sequences were recombined into this backbone. In addition, to generate new diversity, variants generated with saturation mutagenesis at different positions were also constructed using SEQ ID NO: 276. The variants were assayed in triplicate for amylase activity at pH 6.8 after pre-incubation under two different conditions. The first condition was a 1 hour gastric challenge at pH 2.75, and the second

condition was a 1 hour intestinal challenge, as described in Example 3. The results (relative to the results for SEQ ID NO: 276) are provided in **Table 4-5**.

[1]Levels of increased activity were determined relative to the reference polypeptide of SEQ ID NO: 276, and defined as follows: "+" > 0.9; "++" > 1.1; and "+++" > 2.				

[0245] Based on the results shown in **Table 4-5**, SEQ ID NO: 308 was chosen as the parent sequence for the next iteration of protein optimization. Beneficial mutations identified from **Table 4-5**, and diversity from homologs were recombined into this backbone. In addition, to generate new diversity, variants with a single mutation at different positions were also constructed using SEQ ID NO: 308. The variants were assayed in triplicate for amylase activity at pH 6.8 after pre-incubations under two different conditions. The first condition was a 2 hour gastric challenge at pH 2.5 and the second condition was a 2 hour intestinal challenge, as described in Example 3. The results (relative to the results for SEQ ID NO: 308) are provided in **Table 4-6**.

[0246] Based on the results shown in **Table 4-6**, SEQ ID NO: 422 was chosen as the parent sequence for the next iteration of protein optimization. Beneficial mutations identified based on the results shown in **Table 4-6** were recombined into this backbone. The variants were assayed in singlicate for amylase activity at pH 6.8 after pre-incubation under two different conditions, the first being a 2 hour gastric challenge at pH 2.3, and the second being a 2 hour intestinal challenge, as described in Example 3. The results (relative to the results for SEQ ID NO: 422) are provided in **Table 4-7**.

[1]Levels of increased activity were determined relative to the reference polypeptide of SEQ ID NO: 422, and defined as follows: "+" > 0.9; "++" > 1.1; and "+++" > 1.5.				

[0247] Based on the results from **Table 4-7**, SEQ ID NO: 456 was chosen as the parent sequence for the next iteration of protein optimization. To generate new diversity, mutations from homologs were recombined using SEQ ID NO: 456, and variants with saturation mutagenesis at different positions were also constructed using this backbone. The variants were assayed in triplicate for amylase activity under unchallenged conditions at pH 6 and pH 7, and also at pH 6 after pre-incubation under two different conditions. The first condition was a 2 hour gastric challenge at pH 2.3, and the second condition was a 2 hour intestinal challenge, as described in Example 3. The results (relative to the results for SEQ ID NO: 456) are provided in **Table 4-8**. In some additional experiments, some variants were assayed in singlicate for amylase activity at pH 6 after a 2 hour gastric challenge at pH 2.3, as described in Example 3. The results (relative to the results for SEQ ID NO: 456) are provided in **Table 4-9**.

[1]Levels of increased activity were determined relative to the reference polypeptide of SEQ ID NO: 456, and defined as follows: "+" > 0.9; "++" > 1.1; "+++" > 1.5; and "++++" > 2.5.			

[0248] Based on the results shown in **Table 4-8**, SEQ ID NO: 546 was chosen as the parent sequence for the next iteration of protein optimization. Beneficial mutations identified from **Table 4-9** were recombined into this backbone. The variants were assayed in triplicate for amylase activity for unchallenged activity at pH 6 and pH 7, as well as at pH 6 after pre-incubation under two different conditions. The first condition was a 2 hour gastric challenge at pH 2.3, and the second condition was a 2 hour intestinal challenge, as described in Example 3. The results (relative to the results for SEQ ID NO: 546) are provided in **Table 4-10**.

[0249] Based on the results shown in **Table 4-10**, SEQ ID NO: 632 was chosen as the parent sequence for the next iteration of protein optimization. To generate new diversity, mutations from homologs were recombined using the backbone. In addition, variants produced using saturation mutagenesis at different positions were also constructed on this backbone. The variants were assayed in triplicate for amylase activity for unchallenged activity at pH 6, and also after pre-incubation under two different conditions. The first condition was a 2 hour gastric challenge at pH 2.3, and the second condition was a 2 hour intestinal challenge, as described in Example 3. The results (relative to the results for SEQ ID NO: 632) are provided in **Table 4-11**.

[1]Levels of increased activity were determined relative to the reference polypeptide of SEQ ID NO: 632, and defined as follows: "+" > 0.9; "++" > 1.1; and "+++" > 1.5.

[0250] Based on the results shown in **Table 4-11**, SEQ ID NO: 664 was chosen as the parent sequence for the next iteration of protein optimization. Mutations from homologs, and any other beneficial mutations identified from all the screening results not yet incorporated were recombined on this backbone. In addition, variants produced using saturation mutagenesis at different positions were also constructed on this backbone. The variants were assayed in triplicate for amylase activity for unchallenged activity at pH 6, and also after pre-incubation under two different conditions. The first condition was a 2 hour gastric challenge at pH 2.3, and the second condition was a 2 hour intestinal challenge, as described in Example 3. The results (relative to the results for SEQ ID NO: 664) are provided in **Table 4-12**.

[0251] In additional experiments, some of the variants from **Table 4-12** were also scaled up for production in shake flasks, and the purified enzymes were assayed for amylase activity for unchallenged activity at pH 6, and also after pre-incubations under two different conditions. The first condition was a 2 hour gastric challenge at pH 3, and the second condition was a 3 hour intestinal challenge, as described in Example 3. The results (relative to the results for SEQ ID NO: 664) are provided in **Table 4-13**.

[1]Levels of increased activity were determined relative to the reference polypeptide of SEQ ID NO: 664, and defined as follows: "+" >0.9; and "++" > 1.1.

[0252] Based on the results shown in **Table 4-10**, SEQ ID NO: 632 was found to have improved gastric stability, but lower intestinal stability compared to SEQ ID NO: 546. Sequence analysis identified a T126R substitution that may have caused the compromised intestinal stability. Based on the results from **Table 4-13**, SEQ ID NO: 780 was chosen as the parent sequence for the next iteration of protein optimization. An NNK library at position 126 was constructed using SEQ ID NO: 780, to rescue the loss of intestinal stability while maintaining gastric stability. The variants were assayed for amylase activity at pH 6 after pre-incubation under three different conditions. The first condition was a 2 hour gastric challenge at pH 2.3, the second condition was a 2 hour trypsin only challenge (no chymotrypsin), and the third condition was a 2 hour incubation with a protease (SEQ ID NO: 20), as described in Example 3. The results (relative to the results for SEQ ID NO: 780) are provided in **Table 4-14**.

EXAMPLE 5: Comparison of Amylase Variant with and without His Tag

[0253] The C-terminus linker and His tag from SEQ ID NO: 810 was removed to generate SEQ ID NO: 1758. Both these variants were grown in HTP and were screened in duplicate for amylase activity at pH 6.8, activity post a 2 hour gastric challenge (1.5 mg/mL pepsin, pH 2.3), a 2 hour intestinal challenge, and a 2 hr protease challenge as described in Example 3. These two variants were found to have similar properties under the different conditions screened, as shown by the absorbance value in **Table 5**.
