Title: AROMATIC THIOETHER LIVER X-RECEPTOR MODULATORS

Abstract: The present invention is directed to selective LXR modulators, small molecule compounds corresponding to Formula I and is further directed to a process of treating a condition in a mammal that is modulated by LXR using a therapeutically effective dose of a compound of Formula I.
AROMATIC THIOETHER LIVER X-RECEPTOR MODULATORS

BACKGROUND

Liver X-receptors (LXRs) are nuclear receptors that regulate the metabolism of several important lipids, including cholesterol and bile acids. Most of the cholesterol in plasma is transported on three major lipoprotein classes; VLDL cholesterol (VLDL-C), LDL cholesterol (LDL-C) and HDL cholesterol (HDL-C). Total cholesterol is the sum of all three lipoproteins. Both VLDL-C and LDL-C are associated with atherogenic processes while HDL-C is believed to facilitate cholesterol removal from tissues (e.g. atherosclerotic plaques) and thus have a protective effect on coronary heart disease.

LXR represents a novel intervention point to regulate the reverse cholesterol transport (RCT) pathway, i.e., the removal of cholesterol from peripheral tissues/cells and subsequent uptake via the liver for disposal.

Removal of cellular cholesterol requires active transport of free cholesterol across the plasma membrane and onto HDL particles. This transfer of cholesterol from inside the cell and onto HDL in the plasma is mediated by ATP binding cassette 1 (ABCA1) transporter protein. The observation that LXR is a key transcriptional activator of ABCA1 in the macrophage, suggests that induction of LXR will lead to an increase in cholesterol efflux from the macrophage. In addition, it is known that LXR regulates the induction of other genes involved in RCT such as apoE and cholesterol ester transport protein (CETP), suggesting that activating the LXR pathway should also lead to increased uptake of cholesterol by the liver. Thus, activation of LXR by a small molecule ligand will lead to an up-regulation of ABCA1 and induction of the reverse cholesterol transport pathway thereby increasing cholesterol efflux to HDL-C and reducing the cholesterol content of atherosclerotic plaques.

Administration

5 The LXR modulators useful in the practice of the present invention can be formulated into pharmaceutical compositions and administered by any means that will deliver a therapeutically effective dose. Such compositions can be administered orally, parenterally, intranasally, by inhalation spray, rectally, intradermally, transdermally, or topically in dosage unit formulations containing conventional nontoxic pharmaceutically acceptable carriers, adjuvants, and vehicles as desired. Topical administration may also involve the use of transdermal administration such as transdermal patches or iontophoresis devices. The term parenteral as used herein includes subcutaneous,

Injectable preparations, for example, sterile injectable aqueous or oleaginous suspensions, can be formulated according to the known art using suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution or suspension in a nontoxic parenterally acceptable diluent or solvent. Among the acceptable vehicles and solvents that may be employed are water, Ringer’s solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose, any bland fixed oil may be employed, including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid are useful in the preparation of injectables. Dimethyl acetamide, surfactants including ionic and non-ionic detergents, and polyethylene glycols can be used. Mixtures of solvents and wetting agents such as those discussed above are also useful.

Suppositories for rectal administration of the compounds discussed herein can be prepared by mixing the active agent with a suitable non-irritating excipient such as cocoa butter, synthetic mono-, di-, or triglycerides, fatty acids, or polyethylene glycols which are solid at ordinary temperatures but liquid at the rectal temperature, and which will therefore melt in the rectum and release the drug.

Solid dosage forms for oral administration may include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the compounds are ordinarily combined with one or more adjuvants appropriate to the indicated route of administration. If administered per os, the compounds can be admixed with lactose, sucrose, starch powder, cellulose esters of alkanoic acids, cellulose alkyl esters, talc, stearic acid, magnesium stearate, magnesium oxide, sodium
and calcium salts of phosphoric and sulfuric acids, gelatin, acacia gum, sodium alginate, polyvinylpyrrolidone, and/or polyvinyl alcohol, and then tableted or encapsulated for convenient administration. Such capsules or tablets can contain a controlled-release formulation as can be provided in a dispersion of active compound in hydroxypropylmethyl cellulose. In the case of capsules, tablets, and pills, the dosage forms can also comprise buffering agents such as sodium citrate, or magnesium or calcium carbonate or bicarbonate. Tablets and pills can additionally be prepared with enteric coatings.

For therapeutic purposes, formulations for parenteral administration can be in the form of aqueous or non-aqueous isotonic sterile injection solutions or suspensions. These solutions and suspensions can be prepared from sterile powders or granules having one or more of the carriers or diluents mentioned for use in the formulations for oral administration. The compounds can be dissolved in water, polyethylene glycol, propylene glycol, ethanol, corn oil, cottonseed oil, peanut oil, sesame oil, benzyl alcohol, sodium chloride, and/or various buffers. Other adjuvants and modes of administration are well and widely known in the pharmaceutical art.

Liquid dosage forms for oral administration can include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, and elixirs containing inert diluents commonly used in the art, such as water. Such compositions can also comprise adjuvants, such as wetting agents, emulsifying and suspending agents, and sweetening, flavoring, and perfuming agents.

The amount of active ingredient that can be combined with the carrier materials to produce a single dosage of the LXR modulator will vary depending upon the patient and the particular mode of administration. In general, the pharmaceutical compositions may contain a LXR modulator in the range of about 1 and 2500 mg, more typically, in the range of about 5 and 1000 mg and still more typically, between about 10 and 500 mg. A daily dose of about 0.1 to 50 mg/kg body weight, or more typically, between about 0.1 and about 25 mg/kg body weight and even more typically, from about 0.5 to 10 mg/kg body weight,
may be appropriate. The daily dose can be administered in one to about four
doses per day. Those skilled in the art will appreciate that dosages may also be
determined with guidance from Goodman & Goldman's *The Pharmacological
Basis of Therapeutics*, Ninth Edition (1996), Appendix II, pp. 1707-1711 and from

**Example 53**

N-[2-[(5-amino-2-methoxybenzyl)thiophenyl]-2,2-dimethylpropanamide hydrochloride

![Diagram Image]

The product of Example 11 dissolved in ethanol and treated with 4 equivalents of Tin(II) dichloride dihydrate at reflux for 4 h. The reaction was cooled, diluted with water, made basic with potassium hydroxide and extracted with ethyl acetate (3X250 mL). The combined organics were washed with water then saturated sodium chloride solution. The solvent was removed in vacuo and the residue dissolved in diethyl ether. 4 N HCl in dioxane was added in excess and the resulting precipitate was filtered by suction to afford the product.

Examples 54-57

The product of Example 53 was combined with an excess of the appropriate aldehyde or ketone in methanol. A solution of sodium cyanoborohydride in methanol was added in and the pH was corrected to 5 with acetic acid. The reaction was agitated for 4 d then PS-TsNHNH2 resin was added and the reaction agitated a further 3 hours. The reactions were filtered and the filtrate was dried to a residue which was chromatographed on silica to afford the product.

**EXAMPLE 61**

5. **LXR reporter gene transactivation assay for High-throughput screen**

Human hepatic cells (Huh-7) were cotransfected with a luciferase reporter gene (pGal4-RE), where transcription of luciferase gene is driven by the Gal4 response element, and a chimeric gene construct of liver X receptor (Gal4DBD-LXRαLBD), which comprises a DNA sequence that encodes a hybrid protein of LXR ligand binding domain (LXRαLBD) and Gal4 DNA-binding domain (Gal4DBD).
The transfection was performed in culture dishes using LipofectAMINE2000 reagent. The transfected cells were harvested 20 hr later and resuspended in assay medium containing RPMI 1640 medium, 2% fetal bovine lipoprotein deficient serum, 100 units/ml penicillin and 100 μg/ml streptomycin.

In screening for LXR modulators, the transfected cells were dispensed in an assay plate (384-well white tissue culture plate) containing the test compounds at 10 μM final concentration and incubated for 24 hr. The effects of test compounds on the activation of LXR_LBD and hence luciferase transcription was determined by measuring the luciferase activity using Steady-Glo luciferase assay substrate. Luciferase activity results are expressed as the fold-induction relative to DMSO controls. Compounds that exhibited >10 fold induction were then retested and the EC_{50} was determined as the concentration necessary to produce 50% of the maximal luciferase activity. Each of the compounds of Examples 1-60 was found to have an EC_{50} of less than 50 μM.
