DEFINITIONS

Unless stated otherwise, the following terms and phrases as used herein are intended to have the following meanings:

When trade names are used herein, applicants intend to independently include the trade name product formulation, the generic drug, and the active pharmaceutical ingredient(s) of the trade name product.

The term "antibody" herein is used in the broadest sense and specifically covers monoclonal antibodies, polyclonal antibodies, dimers, multimers, multispecific antibodies (e.g., bispecific antibodies), and antibody fragments, so long as they exhibit the desired biological activity (Miller et al (2003) Jour, of Immunology 170:4854-4861). Antibodies may be murine, human, humanized, chimeric, or derived from other species. An antibody is a protein generated by the immune system that is capable of recognizing and binding to a specific antigen. (Janeway, C, Travers, P,., Walport, M., Shlomchik (2001) Immuno Biology, 5th Ed., Garland Publishing, New York). A target antigen generally has numerous binding sites, also called epitopes, recognized by CDRs on multiple antibodies. Each
antibody that specifically binds to a different epitope has a different structure. Thus, one antigen may have more than one corresponding antibody. An antibody includes a full-length immunoglobulin molecule or an immunologically active portion of a full-length immunoglobulin molecule, i.e., a molecule that contains an antigen binding site that immunospecifically binds an antigen of a target of interest or part thereof, such targets including but not limited to, cancer cell or cells that produce autoimmune antibodies associated with an autoimmune disease. The immunoglobulin disclosed herein can be of any type (e.g., IgG, IgE, IgM, IgD, and IgA), class (e.g., IgG1, IgG2, IgG3, IgG4, IgA1 and IgA2) or subclass of immunoglobulin molecule. The immunoglobulins can be derived from any species. In one aspect, however, the immunoglobulin is of human, murine, or rabbit origin.

"Antibody fragments" comprise a portion of a full length antibody, generally the antigen binding or variable region thereof. Examples of antibody fragments include Fab, Fab', F(ab')2, and Fv fragments; diabodies; linear antibodies; minibodies (Olafsen et al (2004) Protein Eng. Design & Sel. 17(4):3 15-323), fragments produced by a Fab expression library, anti-idiotypic (anti-Id) antibodies, CDR (complementary determining region), and epitope-binding fragments of any of the above which immunospecifically bind to cancer cell antigens, viral antigens or microbial antigens, single-chain antibody molecules; and multispecific antibodies formed from antibody fragments.

The term "monoclonal antibody" as used herein refers to an antibody obtained from a population of substantially homogeneous antibodies, i.e., the individual antibodies comprising the population are identical except for possible naturally occurring mutations that may be present in minor amounts. Monoclonal antibodies are highly specific, being directed against a single antigenic site. Furthermore, in contrast to polyclonal antibody preparations which include different antibodies directed against different determinants (epitopes), each monoclonal antibody is directed against a single determinant on the antigen. In addition to their specificity, the monoclonal antibodies are advantageous in that they may be synthesized uncontaminated by other antibodies. The modifier "monoclonal" indicates the character of the antibody as being obtained from a substantially homogeneous population of antibodies, and is not to be construed as requiring production of the antibody by any particular method. For example, the monoclonal antibodies to be used in accordance with the present invention may be made by the hybridoma method first described by Kohler et al (1975) Nature, 256:495, or may be made by recombinant DNA methods (see for example: US 4816567; US 5807715). The monoclonal antibodies may also be isolated from phage antibody libraries.

The monoclonal antibodies herein specifically include "chimeric" antibodies in which a portion of the heavy and/or light chain is identical with or homologous to corresponding sequences in antibodies derived from a particular species or belonging to a particular antibody class or subclass, while the remainder of the chain(s) is identical with or homologous to corresponding sequences in antibodies derived from another species or belonging to another antibody class or subclass, as well as fragments of such antibodies, so long as they exhibit the desired biological activity (US 4816567; and Morrison et al (1984) Proc. Natl. Acad. Sci. USA, 81:6851-6855). Chimeric antibodies of interest herein include "primatized" antibodies comprising variable domain antigen-binding sequences derived from a non-human primate (e.g., Old World Monkey, Ape, etc.) and human constant region sequences.

An "intact antibody" herein is one comprising a VL and VH domains, as well as a light chain constant domain (CL) and heavy chain constant domains, CHI, CH2 and CH3. The constant domains may be native sequence constant domains (e.g., human native sequence constant domains) or amino acid sequence variant thereof. The intact antibody may have one or more "effector functions" which refer to those biological activities attributable to the Fc constant region (a native sequence Fc region or amino acid sequence variant Fc region) of an antibody. Examples of antibody effector functions include Clq binding; complement dependent cytotoxicity; Fc receptor binding; antibody-dependent cell-mediated cytotoxicity (ADCC); phagocytosis; and down regulation of cell surface receptors such as B cell receptor and BCR.

The term "Fc region" herein is used to define a C-terminal region of an immunoglobulin heavy chain that contains at least a portion of the constant region. The term includes native sequence Fc regions and variant Fc regions. In one embodiment, a human IgG heavy chain Fc region extends from Cys226, or from Pro230, to the carboxyl-terminus of the heavy chain. However, the C-terminal lysine (Lys447) of the Fc region may or may not be present. Unless otherwise specified herein, numbering of amino acid residues in the Fc region or constant region is according to the EU numbering system, also called the EU index, as described in Kabat et al., *Sequences of Proteins of Immunological Interest*, 5th Ed. Public Health Service, National Institutes of Health, Bethesda, MD, 1991.

"Framework" or "FR" refers to variable domain residues other than hypervariable region (HVR) residues. The FR of a variable domain generally consists of four FR domains:
FR1, FR2, FR3, and FR4. Accordingly, the HVR and FR sequences generally appear in the following sequence in VH (or VL): FR1-H1(L1)-FR2-H2(L2)-FR3-H3(L3)-FR4.

Depending on the amino acid sequence of the constant domain of their heavy chains, intact antibodies can be assigned to different "classes." There are five major classes of intact immunoglobulin antibodies: IgA, IgD, IgE, IgG, and IgM, and several of these may be further divided into "subclasses" (isotypes), e.g., IgGl, IgG2, IgG3, IgG4, IgA, and IgA2. The heavy-chain constant domains that correspond to the different classes of antibodies are called α, δ, ε, γ, and μ, respectively. The subunit structures and three-dimensional configurations of different classes of immunoglobulins are well known. Ig forms include hinge-modifications or hingeless forms (Roux et al (1998) J. Immunol. 161:4083-4090; Lund et al (2000) Eur. J. Biochem. 267:7246-7256; US 2005/0048572; US 2004/0229310).

A "human antibody" is one which possesses an amino acid sequence which corresponds to that of an antibody produced by a human or a human cell or derived from a non-human source that utilizes human antibody repertoires or other human antibody-encoding sequences. This definition of a human antibody specifically excludes a humanized antibody comprising non-human antigen-binding residues.

A "human consensus framework" is a framework which represents the most commonly occurring amino acid residues in a selection of human immunoglobulin VL or VH framework sequences. Generally, the selection of human immunoglobulin VL or VH sequences is from a subgroup of variable domain sequences. Generally, the subgroup of sequences is a subgroup as in Kabat et al., *Sequences of Proteins of Immunological Interest*, Fifth Edition, NIH Publication 91-3242, Bethesda MD (1991), vols. 1-3. In one embodiment, for the VL, the subgroup is subgroup kappa I as in Kabat et al, *supra*. In one embodiment, for the VH, the subgroup is subgroup III as in Kabat et al, *supra*.

A "humanized" antibody refers to a chimeric antibody comprising amino acid residues from non-human HVRs and amino acid residues from human FRs. In certain embodiments, a humanized antibody will comprise substantially all of at least one, and typically two, variable domains, in which all or substantially all of the HVRs (e.g., CDRs) correspond to those of a non-human antibody, and all or substantially all of the FRs correspond to those of a human antibody. A humanized antibody optionally may comprise at least a portion of an antibody constant region derived from a human antibody. A "humanized form" of an antibody, e.g., a non-human antibody, refers to an antibody that has undergone humanization.
The term "hypervariable region" or "HVR," as used herein, refers to each of the regions of an antibody variable domain which are hypervariable in sequence and/or form structurally defined loops ("hypervariable loops"). Generally, native four-chain antibodies comprise six HVRs; three in the VH (HI, H2, H3), and three in the VL (LI, L2, L3). HVRs generally comprise amino acid residues from the hypervariable loops and/or from the "complementarity determining regions" (CDRs), the latter being of highest sequence variability and/or involved in antigen recognition. Exemplary hypervariable loops occur at amino acid residues 26-32 (LI), 50-52 (L2), 91-96 (L3), 26-32 (HI), 53-55 (H2), and 96-101 (H3). (Chothia and Lesk, J. Mol. Biol. 196:901-917 (1987)). Exemplary CDRs (CDR-L1, CDR-L2, CDR-L3, CDR-H1, CDR-H2, and CDR-H3) occur at amino acid residues 24-34 of LI, 50-56 of L2, 89-97 of L3, 31-35B of HI, 50-65 of H2, and 95-102 of H3. (Kabat et al., Sequences of Proteins of Immunological Interest, 5th Ed. Public Health Service, National Institutes of Health, Bethesda, MD (1991).) With the exception of CDR1 in VH, CDRs generally comprise the amino acid residues that form the hypervariable loops. CDRs also comprise "specificity determining residues," or "SDRs," which are residues that contact antigen. SDRs are contained within regions of the CDRs called abbreviated-CDRs, or a-CDRs. Exemplary a-CDRs (a-CDR-L1, a-CDR-L2, a-CDR-L3, a-CDR-H1, a-CDR-H2, and a-CDR-H3) occur at amino acid residues 31-34 of LI, 50-55 of L2, 89-96 of L3, 31-35B of HI, 50-58 of H2, and 95-102 of H3. (See Almagro and Fransson, Front. Biosci. 13:1619-1633 (2008).) Unless otherwise indicated, HVR residues and other residues in the variable domain (e.g., FR residues) are numbered herein according to Kabat et al., supra.

The term "variable region" or "variable domain" refers to the domain of an antibody heavy or light chain that is involved in binding the antibody to antigen. The variable domains of the heavy chain and light chain (VH and VL, respectively) of a native antibody generally have similar structures, with each domain comprising four conserved framework regions (FRs) and three hypervariable regions (HVRs). (See, e.g., Kindt et al. Kuby Immunology, 6th ed., W.H. Freeman and Co., page 91 (2007).) A single VH or VL domain may be sufficient to confer antigen-binding specificity. Furthermore, antibodies that bind a particular antigen may be isolated using a VH or VL domain from an antibody that binds the antigen to screen a library of complementary VL or VH domains, respectively. See, e.g., Portolano et al., J. Immunol. 150:880-887 (1993); Clarkson et al, Nature 352:624-628 (1991).

The term "vector," as used herein, refers to a nucleic acid molecule capable of propagating another nucleic acid to which it is linked. The term includes the vector as a self-replicating nucleic acid structure as well as the vector incorporated into the genome of a host.
cell into which it has been introduced. Certain vectors are capable of directing the expression of nucleic acids to which they are operatively linked. Such vectors are referred to herein as "expression vectors."

The term "substituent" denotes an atom or a group of atoms replacing a hydrogen atom on the parent molecule. The term "substituted" denotes that a specified group bears one or more substituents. Where any group may carry multiple substituents and a variety of possible substituents is provided, the substituents are independently selected and need not to be the same. The terms "heterocycle," "heterocyclyl" and "heterocyclic ring" are used interchangeably herein and refer to a saturated or a partially unsaturated (i.e., having one or more double and/or triple bonds within the ring) carbocyclic radical of 3 to about 20 ring atoms in which at least one ring atom is a heteroatom selected from nitrogen, oxygen, phosphorus and sulfur, the remaining ring atoms being C, where one or more ring atoms is optionally substituted independently with one or more substituents described below. A heterocycle may be a monocycle having 3 to 7 ring members (2 to 6 carbon atoms and 1 to 4 heteroatoms selected from N, O, P, and S) or a bicycle having 7 to 10 ring members (4 to 9 carbon atoms and 1 to 6 heteroatoms selected from N, O, P, and S), for example: a bicyclo[4,5], [5,5], [5,6], or [6,6] system. The term "chiral" refers to molecules which have the property of non-superimposability of the mirror image partner, while the term "achiral" refers to molecules which are superimposable on their mirror image partner.

The term "stereoisomers" refers to compounds which have identical chemical constitution, but differ with regard to the arrangement of the atoms or groups in space.
"Diastereomer" refers to a stereoisomer with two or more centers of chirality and whose molecules are not mirror images of one another. Diastereomers have different physical properties, e.g. melting points, boiling points, spectral properties, and reactivities. Mixtures of diastereomers may separate under high resolution analytical procedures such as electrophoresis and chromatography.

"Enantiomers" refer to two stereoisomers of a compound which are non-superimposable mirror images of one another.

Stereochemical definitions and conventions used herein generally follow S. P. Parker, Ed., McGraw-Hill Dictionary of Chemical Terms (1984) McGraw-Hill Book Company, New York; and Eliel, E. and Wilen, S., Stereochemistry of Organic Compounds (1994) John Wiley & Sons, Inc., New York. Many organic compounds exist in optically active forms, i.e., they have the ability to rotate the plane of plane-polarized light. In describing an optically active compound, the prefixes D and L, or R and S, are used to denote the absolute configuration of the molecule about its chiral center(s). The prefixes d and l or (+) and (-) are employed to designate the sign of rotation of plane-polarized light by the compound, with (-) or 1 meaning that the compound is levorotatory. A compound prefixed with (+) or d is dextrorotatory. For a given chemical structure, these stereoisomers are identical except that they are mirror images of one another. A specific stereoisomer may also be referred to as an enantiomer, and a mixture of such isomers is often called an enantiomeric mixture. A 50:50 mixture of enantiomers is referred to as a racemic mixture or a racemate, which may occur where there has been no stereoselection or stereospecificity in a chemical reaction or process. The terms "racemic mixture" and "racemate" refer to an equimolar mixture of two enantiomeric species, devoid of optical activity.

The phrase "pharmaceutically acceptable salt," as used herein, refers to pharmaceutically acceptable organic or inorganic salts of an antibody-drug conjugate (ADC). Exemplary salts include, but are not limited, to sulfate, citrate, acetate, oxalate, chloride, bromide, iodide, nitrate, bisulfate, phosphate, acid phosphate, isonicotinate, lactate, salicylate, acid citrate, tartrate, oleate, tannate, pantothenate, bitartrate, ascorbate, succinate, maleate, gentisinate, fumarate, gluconate, glucuronate, saccharate, formate, benzoate, glutamate, methanesulfonate, ethanesulfonate, benzenesulfonate,/?-toluenesulfonate, and pamoate (i.e., 1,1'-methylene-bis-(2-hydroxy-3-naphthoate)) salts. A pharmaceutically acceptable salt may involve the inclusion of another molecule such as an acetate ion, a succinate ion or other counterion. The counterion may be any organic or inorganic moiety that stabilizes the charge on the parent compound. Furthermore, a pharmaceutically acceptable salt may have more
than one charged atom in its structure. Instances where multiple charged atoms are part of
the pharmaceutically acceptable salt can have multiple counter ions. Hence, a
pharmaceutically acceptable salt can have one or more charged atoms and/or one or more
counterion.

25 CYSTEINE ENGINEERED ANTIBODIES

The compounds of the invention include antibody-drug conjugates comprising
cysteine engineered antibodies where one or more amino acids of a wild-type or parent
antibody are replaced with a cysteine amino acid. Any form of antibody may be so
engineered, i.e. mutated. For example, a parent Fab antibody fragment may be engineered to
form a cysteine engineered Fab, referred to herein as "ThioFab." Similarly, a parent
monoclonal antibody may be engineered to form a "ThioMab." It should be noted that a
single site mutation yields a single engineered cysteine residue in a ThioFab, while a single
site mutation yields two engineered cysteine residues in a ThioMab, due to the dimeric nature
of the IgG antibody. Mutants with replaced ("engineered") cysteine (Cys) residues are evaluated for the reactivity of the newly introduced, engineered cysteine thiol groups. The thiol reactivity value is a relative, numerical term in the range of 0 to 1.0 and can be measured for any cysteine engineered antibody. Thiol reactivity values of cysteine engineered antibodies of the invention are in the ranges of 0.6 to 1.0; 0.7 to 1.0; or 0.8 to 1.0.

Cysteine amino acids may be engineered at reactive sites in an antibody and which do not form intrachain or intermolecular disulfide linkages (Junutula, et al., 2008b Nature Biotech., 26(8):925-932; Dornan et al (2009) Blood 114(13):2721-2729; US 7521541; US 7723485; WO2009/052249, Shen et al (2012) Nature Biotech., 30(2):184-191; Junutula et al (2008) Jour of Immun. Methods 332:41-52). The engineered cysteine thiols may react with linker reagents or the linker-drug intermediates of the present invention which have thiol-reactive, electrophilic groups such as maleimide or alpha-halo amides to form ADC with cysteine engineered antibodies (ThioMabs) and the drug (D) moiety. The location of the drug moiety can thus be designed, controlled, and known. The drug loading can be controlled since the engineered cysteine thiol groups typically react with thiol-reactive linker reagents or linker-drug intermediates in high yield. Engineering an antibody to introduce a cysteine amino acid by substitution at a single site on the heavy or light chain gives two new cysteines on the symmetrical antibody. A drug loading near 2 can be achieved and near homogeneity of the conjugation product ADC.

Cysteine engineered antibodies of the invention preferably retain the antigen binding capability of their wild type, parent antibody counterparts. Thus, cysteine engineered antibodies are capable of binding, preferably specifically, to antigens. Such antigens include, for example, tumor-associated antigens (TAA), cell surface receptor proteins and other cell surface molecules, transmembrane proteins, signaling proteins, cell survival regulatory factors, cell proliferation regulatory factors, molecules associated with (for e.g., known or suspected to contribute functionally to) tissue development or differentiation, lymphokines, cytokines, molecules involved in cell cycle regulation, molecules involved in vasculogenesis and molecules associated with (for e.g., known or suspected to contribute functionally to) angiogenesis. The tumor-associated antigen may be a cluster differentiation factor (i.e., a CD protein). An antigen to which a cysteine engineered antibody is capable of binding may be a member of a subset of one of the above-mentioned categories, wherein the other subset(s) of said category comprise other molecules/antigens that have a distinct characteristic (with respect to the antigen of interest).
Cysteine engineered antibodies are prepared for conjugation with linker-drug intermediates by reduction and reoxidation of intrachain disulfide groups (Example 19).

Cysteine engineered antibodies which may be useful in the antibody-drug conjugates of the invention in the treatment of cancer include, but are not limited to, antibodies against cell surface receptors and tumor-associated antigens (TAA). Tumor-associated antigens are known in the art, and can be prepared for use in generating antibodies using methods and information which are well known in the art. In attempts to discover effective cellular targets for cancer diagnosis and therapy, researchers have sought to identify transmembrane or otherwise tumor-associated polypeptides that are specifically expressed on the surface of one or more particular type(s) of cancer cell as compared to on one or more normal non-cancerous cell(s). Often, such tumor-associated polypeptides are more abundantly expressed on the surface of the cancer cells as compared to on the surface of the non-cancerous cells. The identification of such tumor-associated cell surface antigen polypeptides has given rise to the ability to specifically target cancer cells for destruction via antibody-based therapies.

Examples of tumor-associated antigens TAA include, but are not limited to, TAA (1)-(51) listed below. For convenience, information relating to these antigens, all of which are known in the art, is listed below and includes names, alternative names, Genbank accession numbers and primary reference(s), following nucleic acid and protein sequence identification conventions of the National Center for Biotechnology Information (NCBI). Nucleic acid and protein sequences corresponding to TAA (1)-(51) are available in public databases such as GenBank. Tumor-associated antigens targeted by antibodies include all amino acid sequence variants and isoforms possessing at least about 70%, 80%, 85%, 90%, or 95% sequence identity relative to the sequences identified in the cited references, or which exhibit substantially the same biological properties or characteristics as a TAA having a sequence found in the cited references. For example, a TAA having a variant sequence generally is able to bind specifically to an antibody that binds specifically to the TAA with the corresponding sequence listed. The sequences and disclosure in the reference specifically recited herein are expressly incorporated by reference.

The parent antibody may also be a fusion protein comprising an albumin-binding peptide (ABP) sequence (Dennis et al. Antibodies of the invention include fusion proteins with ABP sequences taught by: (i) Dennis et al (2002) J Biol Chem. 277:35035-35043 at Tables III and IV, page 35038; (ii) US 20040001827 at [0076]; and (iii) WO 01/45746 at pages 12-13, and all of which are incorporated herein by reference.

To prepare a cysteine engineered antibody by mutagenesis, DNA encoding an amino acid sequence variant of the starting polypeptide is prepared by a variety of methods known in the art. These methods include, but are not limited to, preparation by site-directed (or oligonucleotide-mediated) mutagenesis, PCR mutagenesis, and cassette mutagenesis of an earlier prepared DNA encoding the polypeptide. Variants of recombinant antibodies may be constructed also by restriction fragment manipulation or by overlap extension PCR with synthetic oligonucleotides. Mutagenic primers encode the cysteine codon replacement(s). Standard mutagenesis techniques can be employed to generate DNA encoding such mutant cysteine engineered antibodies. General guidance can be found in Sambrook et al Molecular Cloning, A Laboratory Manual, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y., 1989; and Ausubel et al Current Protocols in Molecular Biology, Greene Publishing and Wiley-Interscience, New York, N.Y., 1993.

Antibodies may be produced using recombinant methods and compositions, e.g., as described in US 4816567. In one embodiment, isolated nucleic acid encodes an amino acid
sequence comprising the VL and/or an amino acid sequence comprising the VH of the antibody (e.g., the light and/or heavy chains of the antibody). In a further embodiment, one or more vectors (e.g., expression vectors) comprising such nucleic acid are provided. In a further embodiment, a host cell comprising such nucleic acid is provided. In one such embodiment, a host cell comprises (e.g., has been transformed with): (1) a vector comprising a nucleic acid that encodes an amino acid sequence comprising the VL of the antibody and an amino acid sequence comprising the VH of the antibody, or (2) a first vector comprising a nucleic acid that encodes an amino acid sequence comprising the VL of the antibody and a second vector comprising a nucleic acid that encodes an amino acid sequence comprising the VH of the antibody. In one embodiment, the host cell is eukaryotic, e.g. a Chinese Hamster Ovary (CHO) cell or lymphoid cell (e.g., Y0, NSO, Sp20 cell). In one embodiment, a method comprises culturing a host cell comprising a nucleic acid encoding the antibody, as provided above, under conditions suitable for expression of the antibody, and optionally recovering the antibody from the host cell (or host cell culture medium).

For recombinant production, nucleic acid encoding an antibody, e.g., as described above, is isolated and inserted into one or more vectors for further cloning and/or expression in a host cell. Such nucleic acid may be readily isolated and sequenced using conventional procedures (e.g., by using oligonucleotide probes that are capable of binding specifically to genes encoding the heavy and light chains of the antibody). Suitable host cells for cloning or expression of antibody-encoding vectors include prokaryotic or eukaryotic cells described herein. For example, antibodies may be produced in bacteria, in particular when glycosylation and Fc effector function are not needed. For expression of antibody fragments and polypeptides in bacteria, see, e.g., US 5648237, US 5789199, and US 5840523. (See also Charlton, *Methods in Molecular Biology, Vol. 248* (B.K.C. Lo, ed., Humana Press, Totowa, NJ, 2003), pp. 245-254, describing expression of antibody fragments in *E. coli*.)

After expression, the antibody may be isolated from the bacterial cell paste in a soluble fraction and can be further purified. In addition to prokaryotes, eukaryotic microbes such as filamentous fungi or yeast are suitable cloning or expression hosts for antibody-encoding vectors, including fungi and yeast strains whose glycosylation pathways have been "humanized," resulting in the production of an antibody with a partially or fully human glycosylation pattern. See Gerngross, *Nat. Biotech.* 22: 1409-1414 (2004), and Li et al, *Nat. Biotech.* 24:210-215 (2006). Suitable host cells for the expression of glycosylated antibody are also derived from multicellular organisms (invertebrates and vertebrates). Examples of invertebrate cells include plant and insect cells. Numerous baculoviral strains have been
identified which may be used in conjunction with insect cells, particularly for transfection of *Spodoptera frugiperda* cells. Plant cell cultures can also be utilized as hosts, such as those described in US 5959177, US 6040498, US 6420548, US 7125978, and US 6417429 (describing PLANTIBODIES™ technology for producing antibodies in transgenic plants). Vertebrate cells may also be used as hosts. For example, mammalian cell lines that are adapted to grow in suspension may be useful. Other examples of useful mammalian host cell lines are monkey kidney CV1 line transformed by SV40 (COS-7); human embryonic kidney line (293 or 293 cells as described, e.g., in Graham et al, *J. Gen Virol.* 36:59 (1977); baby hamster kidney cells (BHK); mouse Sertoli cells (TM4 cells as described, e.g., in Mather, *Biol. Reprod.* 23:243-251 (1980); monkey kidney cells (CV1); African green monkey kidney cells (VERO-76); human cervical carcinoma cells (HELA); canine kidney cells (MDCK; buffalo rat liver cells (BRL 3A); human lung cells (W138); human liver cells (Hep G2); mouse mammary tumor (MMT 060562); TRI cells, as described, e.g., in Mather et al, *Annals N.Y. Acad. Sci.* 383:44-68 (1982); MRC 5 cells; and FS4 cells. Other useful mammalian host cell lines include Chinese hamster ovary (CHO) cells, including DHFR-CHO cells (Urlaub et al., *Proc. Natl. Acad. Sci. USA* 77:4216 (1980)); and myeloma cell lines such as Y0, NSO and Sp2/0. For a review of certain mammalian host cell lines suitable for antibody production, see, e.g., Yazaki and Wu, *Methods in Molecular Biology, Vol. 248* (B.K.C. Lo, ed., Humana Press, Totowa, NJ), pp. 255-268 (2003).

Site-directed mutagenesis is one method for preparing substitution variants, i.e. mutant proteins (Carter (1985) et al. *Nucleic Acids Res.* 13:4431-4443; Ho et al. (1989) *Gene* (Amst.) 77:51-59; and Kunkel et al (1987) *Proc. Natl. Acad. Sci. USA* 82:488). Starting DNA is altered by first hybridizing an oligonucleotide encoding the desired mutation to a single strand of such starting DNA. After hybridization, a DNA polymerase is used to synthesize an entire second strand, using the hybridized oligonucleotide as a primer, and using the single strand of the starting DNA as a template. Thus, the oligonucleotide encoding the desired mutation is incorporated in the resulting double-stranded DNA. Site-directed mutagenesis may be carried out within the gene expressing the protein to be mutagenized in an expression plasmid and the resulting plasmid may be sequenced to confirm the introduction of the desired cysteine replacement mutations (Liu et al (1998) *J. Biol. Chem.* 273:20252-20260). Site-directed mutagenesis protocols and formats are widely available, e.g. QuikChange® Multi Site-Directed Mutagenesis Kit (Stratagene, La Jolla, CA).
PCR mutagenesis is also suitable for making amino acid sequence variants of the starting polypeptide. See Higuchi, (1990) in PCR Protocols, pp. 177-183, Academic Press; Ito et al (1991) Gene 102:67-70; Bernhard et al (1994) Bioconjugate Chem., 5:126-132; and Vallette et al (1989) Nuc. Acids Res., 17:723-733. Briefly, when small amounts of template DNA are used as starting material in a PCR, primers that differ slightly in sequence from the corresponding region in a template DNA can be used to generate relatively large quantities of a specific DNA fragment that differs from the template sequence only at the positions where the primers differ from the template.

Another method for preparing variants, cassette mutagenesis, is based on the technique described by Wells et al (1985) Gene, 34:3 15-323. The starting material is the plasmid (or other vector) comprising the starting polypeptide DNA to be mutated. The codon(s) in the starting DNA to be mutated are identified. There must be a unique restriction endonuclease site on each side of the identified mutation site(s). If no such restriction sites exist, they may be generated using the above described oligonucleotide-mediated mutagenesis method to introduce them at appropriate locations in the starting polypeptide DNA. The plasmid DNA is cut at these sites to linearize it. A double-stranded oligonucleotide encoding the sequence of the DNA between the restriction sites but containing the desired mutation(s) is synthesized using standard procedures, wherein the two strands of the oligonucleotide are synthesized separately and then hybridized together using standard techniques. This double-stranded oligonucleotide is referred to as the cassette. This cassette is designed to have 5’ and 3’ ends that are compatible with the ends of the linearized plasmid, such that it can be directly ligated to the plasmid. This plasmid now contains the mutated DNA sequence. Mutant DNA containing the encoded cysteine replacements can be confirmed by DNA sequencing.

In certain embodiments, one or more amino acid modifications may be introduced into the Fc region of an antibody provided herein, thereby generating an Fc region variant. The Fc region variant may comprise a human Fc region sequence (e.g., a human IgGl, IgG2, IgG3 or IgG4 Fc region) comprising an amino acid modification (e.g. a substitution) at one or more amino acid positions.
In certain embodiments, the invention contemplates an antibody variant that possesses some but not all effector functions, which make it a desirable candidate for applications in which the half-life of the antibody in vivo is important yet certain effector functions (such as complement and ADCC) are unnecessary or deleterious. *In vitro* and/or *in vivo* cytotoxicity assays can be conducted to confirm the reduction/depletion of CDC and/or ADCC activities. For example, Fc receptor (FcR) binding assays can be conducted to ensure that the antibody lacks FcR binding (hence likely lacking ADCC activity), but retains FcRn binding ability.

ANTIBODY-DRUG CONJUGATES (ADC)

The antibody-drug conjugate (ADC) compounds of the invention comprise an antibody specific for a tumor-associated antigen linked to a potent CBI dimer drug moiety, and include those with therapeutic activity, effective against a number of hyperproliferative disorders, including cancer. The biological activity of the drug moiety is modulated by conjugation to an antibody. The ADC of the invention selectively deliver an effective dose of the CBI dimer drug, or toxin, to tumor cell or site whereby greater selectivity, i.e. a lower efficacious dose, may be achieved while increasing the therapeutic index ("therapeutic window"). In an exemplary embodiment, the ADC compounds include a cysteine-engineered antibody conjugated, i.e. covalently attached by a linker, to the CBI dimer drug moiety.

An antibody-drug conjugate compound of the invention has the formula:
Ab-(L-D)$_p$

wherein:
Ab is an antibody;
L is a linker having the formula:

-Str-(Pep)$_m$-(Sp)$_n$-

where Str is a stretcher unit covalently attached to the antibody; Pep is an optional peptide unit of two to twelve amino acid residues, Sp is an optional spacer unit covalently attached to a dimer drug moiety, and m and n are independently selected from 0 and 1;

p is an integer from 1 to 8;

D is the dimer drug moiety having the formula:

\[
\begin{align*}
&\text{Cl} \\
&\text{N} \\
&\text{O} \\
&\text{T} \\
&\text{D'} \\
&\text{X}^1 \text{R}^1 \\
&\text{R}^2
\end{align*}
\]

where

R$^1$ is selected from H, P(0)$_3$H$_2$, C(0)NR$^a$R$^b$, or a bond to L;
R$^2$ is selected from H, P(0)$_3$H$_2$, C(0)NR$^a$R$^b$, or a bond to L;
R$^a$ and R$^b$ are independently selected from H and Ci-C$_6$ alkyl optionally substituted with one or more F,
or R$^a$ and R$^b$ form a five or six membered heterocyclyl group;
T is a tether group selected from C$_3$-Ci$_2$ alkylene, Y, (Ci-C$_6$ alkylene)-Y-(Ci-C$_6$ alkylene), (Ci-C$_6$ alkylene)-Y-(Ci-C$_6$ alkylene)-Y-(Ci-C$_6$ alkylene), (C$_2$-C$_6$ alkylene)-Y-(C$_2$-C$_6$ alkylene), and (C$_2$-C$_6$ alkynylene)-Y-(C$_2$-C$_6$ alkynylene);
where Y is independently selected from O, S, NR$^1$, aryl, and heteroaryl;
where alkylene, alkenylene, aryl, and heteroaryl are independently and optionally substituted with F, OH, 0(Ci-C$_6$ alkyl), NH$_2$, NHCH$_3$, N(CH$_3$)$_2$, OP(0)$_3$H$_2$, and Ci-C$_6$ alkyl, where alkyl is optionally substituted with one or more F;
or alkylene, alkenylene, aryl, and heteroaryl are independently and optionally substituted with a bond to L;
D' is a drug moiety selected from:

```
\[ \text{\begin{array}{c}

  \end{array}} \]
```

where the wavy line indicates the site of attachment to T;

\( X^1 \) and \( X^2 \) are independently selected from O and \( NR^3 \), where \( R^3 \) is selected from H and \( \text{C}_6 \) alkyl optionally substituted with one or more F;

\( R^4 \) is H, \( \text{C}_2 \text{OR} \) where R is \( \text{C}_6 \) alkyl or benzyl; and

\( R^5 \) is H.

In one embodiment, \( R^a \) and \( R^b \) form a five or six membered heterocyclyl group selected from N-methylpiperazinyl, morpholinyl, piperidyl, and pyrrolidinyl.

In one embodiment, the drug moiety may be joined to the antibody via a protease cleavable, peptide linker cleavable by cathepsin B, a lysosomal protease found in most mammalian cell types (US 6214345; Dubowchik et al (2002) Bioconj. Chem. 13:855-869).

While the invention is not limited or defined by any particular mechanism of action, the ADC may act as a pro-drug in that the drug is inactive until the linker is cleaved. The ADC is able to concentrate the active drug specifically in a tumor cell location where disease may be poorly treated by conventional chemotherapy. In other embodiments, the drug moiety is attached to the antibody via a non-peptide, non-protease cleavable linker, which may include functionality such as disulfide or succinimidyl groups.
The number of drug moieties which may be conjugated via a reactive linker moiety to an antibody molecule may be limited by the number of free cysteine residues, which are introduced by the methods described herein. Exemplary ADC therefore comprise antibodies which have 1, 2, 3, or 4 engineered cysteine amino acids (Lyon, R. et al (2012) Methods in Enzym. 502:123-138).

In one embodiment, the antibody-drug conjugate compound has the formula:

where AA1 and AA2 are independently selected from an amino acid side chain. The amino acid side chain is independently selected from H, -CH$_3$, -CH$_2$(C$_6$H$_5$), -CH$_2$CH$_2$CH$_2$NH$_2$, -CH$_2$CH$_2$CH$_2$NHCH(NH)NH$_2$, -CHCH(CH$_3$)CH$_3$, and -CH$_2$CH$_2$CH$_2$NHC(0)NH$_2$.

In one embodiment, the antibody-drug conjugate compound has the formula:

**DRUG LOADING OF ADC**

The drug loading is the average number of CBI drug moieties per antibody. Drug loading may range from 1 to 8 drugs (D) per antibody (Ab), i.e. where 1, 2, 3, 4, 5, 6, 7, and 8 drug moieties are covalently attached to the antibody. Compositions of ADC include collections of antibodies conjugated with a range of drugs, from 1 to 8. The average number of drugs per antibody in preparations of ADC from conjugation reactions may be characterized by conventional means such as mass spectroscopy, ELISA assay, electrophoresis, and HPLC. The quantitative distribution of ADC in terms of \( p \) may also be
determined. By ELISA, the averaged value of p in a particular preparation of ADC may be determined (Hamblett et al (2004) Clin. Cancer Res. 10:7063-7070; Sanderson et al (2005) Clin. Cancer Res. 11:843-852). However, the distribution of p (drug) values is not discernible by the antibody-antigen binding and detection limitation of ELISA. Also, ELISA assay for detection of antibody-drug conjugates does not determine where the drug moieties are attached to the antibody, such as the heavy chain or light chain fragments, or the particular amino acid residues. In some instances, separation, purification, and characterization of homogeneous ADC where p is a certain value from ADC with other drug loadings may be achieved by means such as reverse phase HPLC or electrophoresis.

For some antibody-drug conjugates, p may be limited by the number of attachment sites on the antibody. For example, an antibody may have only one or several cysteine thiol groups, or may have only one or several sufficiently reactive thiol groups through which a linker may be attached. Higher drug loading, e.g. p >5, may cause aggregation, insolubility, toxicity, or loss of cellular permeability of certain antibody-drug conjugates.

Typically, fewer than the theoretical maximum of drug moieties is conjugated to an antibody during a conjugation reaction. An antibody may contain, for example, many lysine residues that do not react with the linker-drug intermediate (X-L-D) or linker reagent. Only the most reactive lysine groups may react with an amine-reactive linker reagent. Also, only the most reactive cysteine thiol groups may react with a thiol-reactive linker reagent or linker-drug intermediate. Generally, antibodies do not contain many, if any, free and reactive cysteine thiol groups which may be linked to a drug moiety. Most cysteine thiol residues in the antibodies of the compounds exist as disulfide bridges and must be reduced with a reducing agent such as dithiothreitol (DTT) or TCEP, under partial or total reducing conditions. The loading (drug/antibody ratio, "DAR") of an ADC may be controlled in several different manners, including: (i) limiting the molar excess of linker-drug intermediate or linker reagent relative to antibody, (ii) limiting the conjugation reaction time or temperature, and (iii) partial or limiting reductive conditions for cysteine thiol modification.

Where more than one nucleophilic or electrophilic group of the antibody reacts with a linker-drug intermediate, or linker reagent followed by CBI dimer drug moiety reagent, then the resulting product is a mixture of ADC compounds with a distribution of drug moieties attached to an antibody, e.g. 1, 2, 3, etc. Liquid chromatography methods such as polymeric reverse phase (PLRP) and hydrophobic interaction (HIC) may separate compounds in the mixture by drug loading value. Preparations of ADC with a single drug loading value (p) may be isolated, however, these single loading value ADCs may still be heterogeneous.
mixtures because the drug moieties may be attached, via the linker, at different sites on the antibody. Thus the antibody-drug conjugate compositions of the invention include mixtures of antibody-drug conjugate compounds where the antibody has one or more drug moieties and where the drug moieties may be attached to the antibody at various amino acid residues.

5 METHODS OF PREPARING ANTIBODY-DRUG CONJUGATES

Exemplary antibody-drug conjugates (ADC) compounds 101-139 of the invention were prepared from linker-drug intermediates 51-68 according to Example 20 and as shown in Table 4.

**IN VITRO CELL PROLIFERATION ASSAYS**

Generally, the cytotoxic or cytostatic activity of an antibody-drug conjugate (ADC) is measured by: exposing mammalian cells having receptor proteins, e.g. HER2, to the antibody of the ADC in a cell culture medium; culturing the cells for a period from about 6 hours to about 5 days; and measuring cell viability. Cell-based *in vitro* assays were used to measure viability (proliferation), cytotoxicity, and induction of apoptosis (caspase activation) of the ADC of the invention.

The *in vitro* potency of antibody-drug conjugates (ADC) was measured by a cell proliferation assay (Example 21). The ADC showed surprising and unexpected potency in
inhibition of tumor cell proliferation. Potency of the ADC was correlated with target antigen expression of the cells. The data of Figures 25-30 demonstrate the tested conjugates are capable of binding to the specific antigen expressed on the surface of cells and causing the death of those cells in vitro.

The CellTiter-Glo® Luminescent Cell Viability Assay is a commercially available (Promega Corp., Madison, WI), homogeneous assay method based on the recombinant expression of Coleoptera luciferase (US 5583024; US5674713; US5700670). This cell proliferation assay determines the number of viable cells in culture based on quantitation of the ATP present, an indicator of metabolically active cells (Crouch et al (1993) J. Immunol. Meth. 160:81-88; US 6602677). The CellTiter-Glo® Assay was conducted in 96 well format, making it amenable to automated high-throughput screening (HTS) (Cree et al (1995) Anticancer Drugs: 6:398-404). The homogeneous assay procedure involves adding the single reagent (CellTiter-Glo® Reagent) directly to cells cultured in serum-supplemented medium. Cell washing, removal of medium and multiple pipetting steps are not required. The system detects as few as 15 cells/well in a 384-well format in 10 minutes after adding reagent and mixing. The cells may be treated continuously with ADC, or they may be treated and separated from ADC. Generally, cells treated briefly, i.e. 3 hours, showed the same potency effects as continuously treated cells.

The homogeneous "add-mix-measure" format results in cell lysis and generation of a luminescent signal proportional to the amount of ATP present. The amount of ATP is directly proportional to the number of cells present in culture. The CellTiter-Glo® Assay generates a "glow-type" luminescent signal, produced by the luciferase reaction, which has a half-life generally greater than five hours, depending on cell type and medium used. Viable cells are reflected in relative luminescence units (RLU). The substrate, Beetle Luciferin, is oxidatively decarboxylated by recombinant firefly luciferase with concomitant conversion of ATP to AMP and generation of photons.

Cell-based in vitro assays are used to measure viability (proliferation), cytotoxicity, and induction of apoptosis (caspase activation) of the ADC of the invention. Generally, the cytotoxic or cytostatic activity of an antibody-drug conjugate (ADC) is measured by:

- exposing mammalian cells expressing antigen such as Her2 or MUC16 polypeptide to ADC in a cell culture medium; culturing the cells for a period from about 6 hours to about 5 days; and measuring cell viability. Mammalian cells useful for cell proliferation assays for anti-MUC16 ADC include: (1) a MUC16 polypeptide-expressing cell line OVCAR-3; (2) a PC3-derived cell line engineered to stably express a portion of the MUC16 polypeptide on its cell
surface (PC3/MUC16); (3) the parental PC3 cell line that does not express the MUC16 polypeptide; and (4) a PC3 cell line that does not express MUC16 polypeptide but carries the vector used to drive exogenous MUC16 expression (PC3/neo).

The anti-CD33 ADC 127 and 129 shows potent, dose
responsive cell-killing activity whereas control, off-target anti-MUC16 ADC 130 shows less activity.

IN VIVO EFFICACY

The \textit{in vivo} efficacy of antibody-drug conjugates (ADC) of the invention can be measured by tumor xenograft studies in mice (Example 22). The \textit{in vivo} efficacy of antibody-drug conjugates (ADC) was measured tumor growth inhibition in mice (Example 21). The ADC showed surprising and unexpected potency in inhibition of tumor growth. Efficacy of the ADC was correlated with target antigen expression of the tumor cells.

The efficacy of antibody-drug conjugates were measured \textit{in vivo} by implanting allografts or xenografts of cancer cells in rodents and treating the tumors with ADC. Variable results are to be expected depending on the cell line, the specificity of antibody binding of the ADC to receptors present on the cancer cells, dosing regimen, and other factors. The \textit{in vivo} efficacy of the ADC was measured using a transgenic explant mouse model expressing moderate to high levels of a tumor-associated antigen, such as Her2, MUC16, and CD33. Subjects were treated once with ADC and monitored over 3-6 weeks to measure the time to tumor doubling, log cell kill, and tumor shrinkage. Follow up dose-response and multi-dose experiments were conducted.

For example, the \textit{in vivo} efficacy of an anti-HER2 ADC of the invention can be measured by a high expressing HER2 transgenic explant mouse model (Phillips et al (2008) Cancer Res. 68:9280-90). An allograft is propagated from the Fo5 mmtv transgenic mouse which does not respond to, or responds poorly to, HERCEPTIN® therapy. Subjects were treated once with ADC at certain dose levels (mg/kg) and placebo buffer control (Vehicle) and monitored over two weeks or more to measure the time to tumor doubling, log cell kill, and tumor shrinkage.

Figure 3.1 shows the efficacy of antibody-drug conjugates in a plot of the \textit{in vivo} fitted tumor volume change over time in MMTV-HER2 Fo5 transgenic mammary tumors inoculated into the mammary fat pad of CRL nu/nu mice after dosing once IV with: (1) Vehicle: Histidine Buffer #8: 20mM Histidine Acetate, pH 5.5, 240mM Sucrose, 0.02% PS20, (2) Thio Hu Anti-CD22 10F4v3 HC A1 18C-MC-MMED-(CBI dimer phos) 110, (3) Thio Hu Anti-CD22 10F4v3 HC A1 18C-MC-vc-PAB-(CBI dimer MePip) 108, (4) Thio Hu Anti-CD22 10F4v3 HC A1 18C-MC-vc-PAB-(CBI dimer phos) 111, (5) Thio Hu Anti-Her2 4D5 HC A1 18C-MC-MMED-(CBI dimer phos) 109, (6) Thio Hu Anti-Her2 4D5 HC A1 18C-MC-

ADMINISTRATION OF ANTIBODY-DRUG CONJUGATES

The antibody-drug conjugates (ADC) of the invention may be administered by any
route appropriate to the condition to be treated. The ADC will typically be administered
parenterally, i.e. infusion, subcutaneous, intramuscular, intravenous, intradermal, intrathecal
and epidural.

PHARMACEUTICAL FORMULATIONS

Pharmaceutical formulations of therapeutic antibody-drug conjugates (ADC) of the
invention are typically prepared for parenteral administration, i.e. bolus, intravenous,
intratumor injection with a pharmaceutically acceptable parenteral vehicle and in a unit
dosage injectable form. An antibody-drug conjugate (ADC) having the desired degree of
purity is optionally mixed with pharmaceutically acceptable diluents, carriers, excipients or
form of a lyophilized formulation or an aqueous solution.

ANTIBODY-DRUG CONJUGATE TREATMENTS

It is contemplated that the antibody-drug conjugates (ADC) of the present invention
may be used to treat various diseases or disorders, e.g. characterized by the overexpression of
a tumor antigen. Exemplary conditions or hyperproliferative disorders include benign or
malignant solid tumors and hematological disorders such as leukemia and lymphoid
malignancies. Others include neuronal, glial, astrocytal, hypothalamic, glandular,
macrophagal, epithelial, stromal, blastocoelic, inflammatory, angiogenic and immunologic,
including autoimmune, disorders.

Generally, the disease or disorder to be treated is a hyperproliferative disease such as
cancer. Examples of cancer to be treated herein include, but are not limited to, carcinoma,
lymphoma, blastoma, sarcoma, and leukemia or lymphoid malignancies. More particular
eamples of such cancers include squamous cell cancer (e.g. epithelial squamous cell cancer),
lung cancer including small-cell lung cancer, non-small cell lung cancer, adenocarcinoma of
the lung and squamous carcinoma of the lung, cancer of the peritoneum, hepatocellular
cancer, gastric or stomach cancer including gastrointestinal cancer, pancreatic cancer,
glioblastoma, cervical cancer, ovarian cancer, liver cancer, bladder cancer, hepatoma, breast
cancer, colon cancer, rectal cancer, colorectal cancer, endometrial or uterine carcinoma,
salivary gland carcinoma, kidney or renal cancer, prostate cancer, vulval cancer, thyroid cancer, hepatic carcinoma, anal carcinoma, penile carcinoma, as well as head and neck cancer.

Autoimmune diseases for which the ADC compounds may be used in treatment include rheumatologic disorders (such as, for example, rheumatoid arthritis, Sjogren's syndrome, scleroderma, lupus such as systemic lupus erythematosus (SLE) and lupus nephritis, polymyositis/dermatomyositis, cryoglobulinemia, anti-phospholipid antibody syndrome, and psoriatic arthritis), osteoarthritis, autoimmune gastrointestinal and liver disorders (such as, for example, inflammatory bowel diseases (e.g., ulcerative colitis and Crohn's disease), autoimmune gastritis and pernicious anemia, autoimmune hepatitis, primary biliary cirrhosis, primary sclerosing cholangitis, and celiac disease), vasculitis (such as, for example, ANCA-associated vasculitis, including Churg-Strauss vasculitis, Wegener's granulomatosis, and polyarteritis), autoimmune neurological disorders (such as, for example, multiple sclerosis, opsoclonus myoclonus syndrome, myasthenia gravis, neuromyelitis optica, Parkinson's disease, Alzheimer's disease, and autoimmune polyneuropathies), renal disorders (such as, for example, glomerulonephritis, Goodpasture's syndrome, and Berger's disease), autoimmune dermatologic disorders (such as, for example, psoriasis, urticaria, hives, pemphigus vulgaris, bullous pemphigoid, and cutaneous lupus erythematosus), hematologic disorders (such as, for example, thrombocytopenic purpura, thrombotic thrombocytopenic purpura, post-transfusion purpura, and autoimmune hemolytic anemia), atherosclerosis, uveitis, autoimmune hearing diseases (such as, for example, inner ear disease and hearing loss), Behcet's disease, Raynaud's syndrome, organ transplant, and autoimmune endocrine disorders (such as, for example, diabetic-related autoimmune diseases such as insulin-dependent diabetes mellitus (IDDM), Addison's disease, and autoimmune thyroid disease (e.g., Graves' disease and thyroiditis)). More preferred such diseases include, for example, rheumatoid arthritis, ulcerative colitis, ANCA-associated vasculitis, lupus, multiple sclerosis, Sjogren's syndrome, Graves' disease, IDDM, pernicious anemia, thyroiditis, and glomerulonephritis.

For the prevention or treatment of disease, the appropriate dosage of an ADC will depend on the type of disease to be treated, as defined above, the severity and course of the disease, whether the molecule is administered for preventive or therapeutic purposes, previous therapy, the patient's clinical history and response to the antibody, and the discretion of the attending physician. The molecule is suitably administered to the patient at one time or over a series of treatments. Depending on the type and severity of the disease, about 1 µg/kg
to 15 mg/kg (e.g. 0.1-20 mg/kg) of molecule is an initial candidate dosage for administration to the patient, whether, for example, by one or more separate administrations, or by continuous infusion. A typical daily dosage might range from about 1 µg/kg to 100 mg/kg or more, depending on the factors mentioned above. An exemplary dosage of ADC to be administered to a patient is in the range of about 0.1 to about 10 mg/kg of patient weight.

ARTICLES OF MANUFACTURE

In another embodiment of the invention, an article of manufacture, or "kit", containing materials useful for the treatment of the disorders described above is provided. The article of manufacture comprises a container and a label or package insert on or associated with the container. Suitable containers include, for example, bottles, vials, syringes, blister pack, etc. The containers may be formed from a variety of materials such as glass or plastic. The container holds an antibody-drug conjugate (ADC) composition which is effective for treating the condition and may have a sterile access port (for example the container may be an intravenous solution bag or a vial having a stopper pierceable by a hypodermic injection needle). At least one active agent in the composition is an ADC. The label or package insert indicates that the composition is used for treating the condition of choice, such as cancer. Alternatively, or additionally, the article of manufacture may further comprise a second (or third) container comprising a pharmaceutically-acceptable buffer, such as bacteriostatic water for injection (BWFI), phosphate-buffered saline, Ringer's solution and dextrose solution. It may further include other materials desirable from a commercial and user standpoint, including other buffers, diluents, filters, needles, and syringes.

EXAMPLES

Example 1  
(S)-l-(chloromethyl)-3 -((S)-l-(chloromethyl)-5 -hydroxy-1H-
benzo[e]indol-3(2H)-yl)-5-oxopentanoyl)-2,3-dihydro-1H-benzo[e]indol-5-yl 2-(2-bromo-N-
methylacetamido)ethyl(methyl)carbamate  51

hydroxy-1H-benzo[e]indole-3(2H)-carboxylate  51a was deprotected with HCl and acylated with glutaroyl dichloride (Figure 1). Instead of preparative HPLC, reaction solvent was removed under vacuum and the resultant residue was triturated with methanol to give 1,5-
bis((S)-l-(Chloromethyl)-5-hydroxy-1H-benzo[e]indol-3(2H)-yl)pentane-1,5-dione  51b as an
off-white solid (yield 51%). $R_f = 0.50$ (ethyl acetate / petroleum ether =2:1). NMR and MS data are identical to the reported value. $[\alpha]_D^{26} = -46.3^\circ$ (c = 0.41, DMA).

To a solution of 51b (650 mg, 1.15 mmol) in DMA (5 mL) cooled in an ice bath was added DIPEA (0.40 mL, 2.31 mmol) and 4-nitrophenyl chloroformate (302 mg, 1.50 mmol). After the mixture was allowed to warm up to room temperature and stirred overnight, tert-butyl methyl(2-(methylamino)ethyl)carbamate (652 mg, 3.00 mmol) was added. The mixture was stirred at room temperature for 7 h and then redistributed between ethyl acetate and cold dilute aqueous NaHCO$_3$. The aqueous phase was extracted with ethyl acetate three times. The combined organic extracts were washed with water followed by brine, dried over anhydrous Na$_2$SO$_4$, and filtered through celite. The solvent was removed and the residue was further purified by column chromatography using gradient mixtures of ethyl acetate and petroleum ether (v/v 1:1 to 4:1) and then ethyl acetate only as eluents to give Boc (S)-l-(chloromethyl)-3-(5-((S)-1-(chloromethyl)-5 -hydroxy-1H-benzo[e]indol-3(2H)-yl)-5-oxopentanoyl)-2,3 -dihydro-lH-benzo[e]indol-5-yl methyl(2-(methylamino)ethyl)carbamate 51c as an off-white solid (359 mg, 40%); mp 157 °C (dec). $[\alpha]_D^{26} = -45.4^\circ$ (c = 1.08, ethyl acetate). Acetic acid (50 mL) was added to a stirred solution of (R)-tert-butyl 1-(chloromethyl)-5-(diphenylmethyleneamino)-1H-benzo[e]indole-3(2H)-carboxylate 53a (1.00 g, 2.01 mmol) in THF-H$_2$O (150 mL/75 mL) at room temperature (r.t.) and the mixture stirred overnight (Figure 2). cyclopropyl product shown in Figure 9 as a yellow oil (345 mg, 19%). (Lajiness J. and Boger

To a solution of 57a (1.60 g, 3.77 mmol) in DCM (15 mL) cooled in an ice bath was
added 4N HCl in dioxane (40 mL). The mixture was allowed to warm up to room
temperature and stirred for 3 h. All volatile components were pumped off to give (S)-5-(
benzoyloxy)-1-(chloromethyl)-2,3-dihydro-1H-benzox[elindole 57b as a hydrochloride salt.
The salt was dissolved in THF (15 mL) and cooled down in an ice bath. Glutaric anhydride
(646 mg, 5.66 mmol), DMAP (46 mg, 0.38 mmol) and pyridine (5 mL) were added and the
resultant mixture was stirred for 4 h at room temperature. After all the volatile components
were pumped off, the residue was dissolved in dilute aq NaHCO$_3$ and washed 3 times with ethyl acetate. The aqueous phase was acidified using IN HCl to a pH of 2 and extracted with ethyl acetate three times. The combined ethyl acetate extracts were washed with water and brine, dried over anhydrous Na$_2$SO$_4$, and filtered through a silica gel pad washing with a mixture of MeOH and ethyl acetate (v/v 1:10). The solvent was removed to give (S)-5-(5-(benzyl/loxy)-1-(chloromethyl)-1H-benzo[e]indol-3(2H)-yl)-5-oxopentanoic acid 57c as an off-white solid (978 mg, 85%).

At -10 °C, to a solution of 57c (978 mg, 2.23 mmol) in THF (20 mL) was added 25% aqueous ammonium formate (20 mL) followed by Pd-C catalyst (10%), wet, 500 mg) and the mixture was stirred at -10 °C for 7 h. More Pd-C catalyst (500 mg) was added and the mixture was stirred at the same temperature overnight. The catalyst was filtered off through celite and the celite was washed with THF. The THF was pumped off from the filtrate and the remaining aqueous solution was extracted with ethyl acetate three times. The combined extracts were washed with water and brine, dried over anhydrous Na$_2$SO$_4$ and filtered.

Removal of solvent gave (S)-5-(1-(chloromethyl)-5-hydroxy-1H-benzo[e]indol-3(2H)-yl)-5-oxopentanoic acid 53h as an off-white solid (487 mg, 63%); H NMR (DMSO) δ 12.08 (br s, 1H), 10.35 (br s, 1H), 8.08 (d, $J$ = 8.0 Hz, 1H), 7.98 (s, 1H), 7.77 (d, $J$ = 8.3 Hz, 1H), 7.50-7.46 (m, 1H), 7.33-7.29 (m, 1H), 4.30 (t, $J$ = 10.5 Hz, 1H), 4.14-4.12 (m, 2H), 3.98 (dd, $J$ = 2.8, 10.9 Hz, 1H), 3.78 (dd, $J$ = 7.8, 10.8 Hz, 1H), 2.63-2.54 (m, 2H), 2.34 (t, $J$ = 7.4 Hz, 2H), 1.99-1.83 (m, 2H) ppm. To a solution of 53h (500 mg, 1.44 mmol) in THF (15 mL) was added tetrazole (3% in acetonitrile, 51 mL, 17.25 mmol) followed by di-tert-butyl-N,N-diisopropyl phosphoramidite (5.73 mL, 17.25 mmol). The mixture was stirred at room temperature overnight then cooled in an ice bath and H$_2$O$_2$ (30% aqueous solution, 3.53 mL, 34.5 mmol) was added dropwise. The resultant mixture was allowed to warm up to room temperature and stirred for 5 h. The reaction was quenched by the addition of 10% aqueous sodium sulphite with cooling in an ice bath. Organic volatiles were removed by rotary evaporator to give an aqueous phase containing suspended oil. Petroleum ether was added and the mixture was stirred for half an hour. The precipitate which formed was collected by filtration, washed with water and petroleum ether, and dried under vacuum to give (S)-5-(1-(chloromethyl)-5-(di-tert-butoxyphosphoryloxy)-1H-benzo[e]indol-3(2H)-yl)-5-oxopentanoic acid 57d (660 mg, 85%) as an off-white foam; H NMR (DMSO) δ 12.07 (br s, 1H), 8.56 (s, 1H), 8.04 (d, $J$ =

To a suspension of 6-(2,5-dioxo-2,5-dihydro-lH-pyrrol-1-yl)hexanoic acid (1.00 g, 4.73 mmol) in DCM (20 mL) cooled in an ice bath was added a drop of DMF and then oxalyl chloride (2.03 mL, 23.67 mmol) dropwise. See Figure 10. The mixture was allowed to warm up to room temperature and stirred overnight giving a dark brown solution. All volatile components were removed by rotary evaporator and then high vacuum pump. The resultant residue was dissolved in DCM (5 mL) and the solvent was removed by rotary evaporator and then high vacuum pump. The above dissolving and removal procedure was repeated once more to give crude 6-maleimidocaproyl chloride as dark brown oil. The resultant mixture was allowed to warm up to room temperature and stirred overnight. The DCM was removed and the residue was dissolved in ethyl acetate. The solution was washed with aqueous NaHCO_3, cold aqueous 5% citric acid, and brine, then dried over anhydrous Na_2SO_4, and filtered through a silica gel pad washing with ethyl acetate. Solvent was removed to give tert-butyl 2-(6-(2,5-dioxo-2,5-dihydro-1H-pyrrol-1-yl)-N-methylhexanamido)ethyl(methyl)carbamate 57e as brown oil (1.33 g, 74%); 1H NMR (DMSO) (mixture of rotamers) δ 7.006 & 7.005 (2xs, 1H), 3.39-3.36 (m, 4H), 3.29-3.25 (m, 2H), 2.92-2.75 (m, 6H, 2NMe), 2.21 (t, J = 7.38 Hz, 2H), 1.50-1.44 (m, 4H), 1.37 (s, 9H), 1.24-1.16 (m, 2H) ppm. To 192 mg (0.53 mmol) of 1 (freshly made by the procedure mentioned above) in DMA (2 mL) was added 2 (100 mg, 0.20 mmol), EDCI hydrochloride (231 mg, 1.21 mmol) and toluenesulfonic acid (3.5 mg, 0.020 mmol). The mixture was stirred overnight and then poured into a mixture of aqueous ammonia and ice. The resulting precipitate was collected by filtration, washed with water, dried and purified by silica gel column chromatography. Gradient mixtures of MeOH and DCM (v/v 1-15%) were used as eluent to provide N-(3-(2,5-bis((E)-3-((S)-1-(chloromethyl)-5-(4-methylpiperazine-1-carbonyloxy)-1H-benzo[elindol-3(2H)-yl)-3-oxoprop-l-enyl)phenylamino)-3-oxopropyl)-6-(2,5-dioxo-2,5-dihydro-1H-pyrrol-1-yl)hexanamide as a yellow solid (30 mg, 13%, HPLC purity 96%), mp 268 °C (dec).

Example 19 Preparation of cysteine engineered antibodies for conjugation by reduction and reoxidation

Under certain conditions, the cysteine engineered antibodies may be made reactive for conjugation with linker-drug intermediates of the invention, such as those in Table 4, by treatment with a reducing agent such as DTT (Cleland's reagent, dithiothreitol) or TCEP (tris(2-carboxyethyl)phosphine hydrochloride; Getz et al (1999) Anal. Biochem. Vol 273:73-80; Soltec Ventures, Beverly, MA). Full length, cysteine engineered monoclonal antibodies (ThioMabs) expressed in CHO cells (Gomez et al (2010) Biotechnology and Bioeng. 105(4):748-760; Gomez et al (2010) Biotechnol. Prog. 26:1438-1445) were reduced, for example with about a 50 fold excess of DTT overnight at room temperature to reduce disulfide bonds which may form between the newly introduced cysteine residues and the cysteine present in the culture media.

Full length, cysteine engineered monoclonal antibodies (ThioMabs) expressed in CHO cells bear cysteine adducts (cystines) or glutathionylated on the engineered cysteines due to cell culture conditions. To liberate the reactive thiol groups of the engineered cysteines, the ThioMabs are dissolved in 500 mM sodium borate and 500 mM sodium chloride at about pH 8.0 and reduced with about a 50-100 fold excess of 1 mM TCEP (tris(2-carboxyethyl)phosphine hydrochloride (Getz et al (1999) Anal. Biochem. Vol 273:73-80; Soltec Ventures, Beverly, MA) for about 1-2 hrs at 37 °C. Alternatively, DTT can be used as reducing agent. The formation of inter-chain disulfide bonds was monitored either by non-reducing SDS-PAGE or by denaturing reverse phase HPLC PLRP column
chromatography. The reduced ThioMab is diluted and loaded onto a HiTrap SP FF column in 10 mM sodium acetate, pH 5, and eluted with PBS containing 0.3M sodium chloride, or 50 mM Tris-Cl, pH 7.5 containing 150 mM sodium chloride.

Disulfide bonds were reestablished between cysteine residues present in the parent Mab by carrying out reoxidation. The eluted reduced ThioMab is treated with 15X or 2 mM dehydroascorbic acid (dhAA) at pH 7 for 3 hours or for 3 hrs in 50 mM Tris-Cl, pH 7.5, or with 2 mM aqueous copper sulfate (CuS0₄) at room temperature overnight. Other oxidants, i.e. oxidizing agents, and oxidizing conditions, which are known in the art may be used. Ambient air oxidation may also be effective. This mild, partial reoxidation step forms intrachain disulfides efficiently with high fidelity. The buffer is exchanged by elution over Sephadex G25 resin and eluted with PBS with 1mM DTPA. The thiol/Ab value is checked by determining the reduced antibody concentration from the absorbance at 280 nm of the solution and the thiol concentration by reaction with DTNB (Aldrich, Milwaukee, WI) and determination of the absorbance at 412 nm.

Liquid chromatography/Mass Spectrometric Analysis was performed on a TSQ Quantum Triple quadrupole™ mass spectrometer with extended mass range (Thermo Electron, San Jose California). Samples were chromatographed on a PRLP-S®, 1000 A, microbore column (50mm x 2.1mm, Polymer Laboratories, Shropshire, UK) heated to 75 °C. A linear gradient from 30-40% B (solvent A: 0.05% TFA in water, solvent B: 0.04% TFA in acetonitrile) was used and the eluent was directly ionized using the electrospray source. Data were collected by the Xcalibur® data system and deconvolution was performed using ProMass® (Novatia, LLC, New Jersey). Prior to LC/MS analysis, antibodies or drug conjugates (50 micrograms) were treated with PNGase F (2 units/ml; PROzyme, San Leandro, CA) for 2 hours at 37 °C to remove N-linked carbohydrates.

Hydrophobic Interaction Chromatography (HIC) samples were injected onto a Butyl HIC NPR column (2.5 micron particle size, 4.6 mm x 3.5 cm) (Tosoh Bioscience) and eluted with a linear gradient from 0 to 70% B at 0.8 ml/min (A: 1.5 M ammonium sulfate in 50 mM potassium phosphate, pH 7, B: 50 mM potassium phosphate pH 7, 20% isopropanol). An Agilent 1100 series HPLC system equipped with a multi wavelength detector and Chemstation software was used to resolve and quantitate antibody species with different ratios of drugs per antibody.
Example 20  Conjugation of linker-drug intermediates to antibodies

After the reduction and reoxidation procedures of Example 19, the antibody is dissolved in PBS (phosphate buffered saline) buffer and chilled on ice. An excess, from about 1.5 molar to 20 equivalents of a linker-drug intermediate, including but not limited to 51-68 in Table 4, with a thiol-reactive functional group such as maleimido or bromoacetamide, is dissolved in DMSO, diluted in acetonitrile and water, and added to the chilled reduced, reoxidized antibody in PBS. After about one hour, an excess of maleimide is added to quench the reaction and cap any unreacted antibody thiol groups. The conjugation mixture may be loaded and eluted through a HiTrap SP FF column to remove excess drug-linker intermediate and other impurities. The reaction mixture is concentrated by centrifugal ultrafiltration and the cysteine engineered antibody drug conjugate is purified and desalted by elution through G25 resin in PBS, filtered through 0.2 µm filters under sterile conditions, and frozen for storage.

By the procedure above, cysteine engineered, antibody drug conjugates 101-133 of Table 3 were prepared.

Example 21  In vitro cell proliferation assay

Efficacy of ADC was measured by a cell proliferation assay employing the following protocol (CELLTITER GLO™ Luminescent Cell Viability Assay, Promega Corp. Technical Bulletin TB288; Mendoza et al (2002) Cancer Res. 62:5485-5488):

1. An aliquot of 100 µl of cell culture containing about 10⁴ cells (SKBR-3, BT474, MCF7 or MDA-MB-468) in medium was deposited in each well of a 96-well, opaque-walled plate.
2. Control wells were prepared containing medium and without cells.
3. ADC was added to the experimental wells and incubated for 3-5 days.
4. The plates were equilibrated to room temperature for approximately 30 minutes.
5. A volume of CELLTITER GLO™ Reagent equal to the volume of cell culture medium present in each well was added.
6. The contents were mixed for 2 minutes on an orbital shaker to induce cell lysis.
7. The plate was incubated at room temperature for 10 minutes to stabilize the luminescence signal.
8. Luminescence was recorded and reported in graphs as RLU = relative luminescence units.
Data are plotted as the mean of luminescence for each set of replicates, with standard deviation error bars. The protocol is a modification of the CELLTITER GLO™ Luminescent Cell Media: SK-BR-3 grow in 50/50/10%FBS/glutamine/250 µg/mL G-418 OVCAR-3 grow in RPMI/20%FBS/glutamine

Example 22 Tumor growth inhibition, in vivo efficacy in high expressing HER2 transgenic explant mice and other tumor models

Tumors were established and allowed to grow to 150-200 mm³ in volume (as measured using calipers) before a single treatment on day 0. Tumor volume was measured using calipers according to the formula: \( V (\text{mm}^3) = 0.5A \times B^2 \), where A and B are the long and short diameters, respectively. Mice were euthanized before tumor volume reached 3000 mm³ or when tumors showed signs of impending ulceration. Data collected from each experimental group (10 mice per group) were expressed as mean ± SE.

The Fo5 mouse mammary tumor model was employed to evaluate the in vivo efficacy of antibody-drug conjugates of the invention after single dose intravenous injections, and as described previously (Phillips GDL, Li GM, Dugger DL, et al. Targeting HER2-Positive Breast Cancer with Trastuzumab-DML, an Antibody-Cytotoxic Drug Conjugate. (2008) Cancer Res. 68:9280-90), incorporated by reference herein. Anti-Her2 ADC were tested with the Fo5 model, a transgenic mouse model in which the human HER2 gene is over-expressed in mammary epithelium under transcriptional regulation of the murine mammary tumor virus promoter (MMTV-HER2) as shown in Figures 31 and 32. The HER2 over-expression causes spontaneous development of a mammary tumor. The mammary tumor of one of these founder animals (founder #5 [Fo5]) has been propagated in subsequent generations of FVB mice by serial transplantation of tumor fragments (~ 2 x 2 mm in size). All studies were conducted in accordance with the Guide for the Care and Use of Laboratory Animals. Each antibody-drug conjugate (single dose) was dosed in nine animals intravenously at the start of the study, and 14 days post-transplant. Initial tumor size was about 200 mm³ volume. Measurements of tumor growth inhibition over time by antibody-drug conjugates of the invention and controls are shown in Figures 31-34.

The OVCAR-3 mammary fat pad transplant efficacy model was employed as described (Chen et al. (2007) Cancer Res 67:4924-4932), evaluating tumor volume after a single intravenous dose and using tumors excised from a mouse bearing an intraperitoneal tumor, then serially passaged into the mammary fat pads of recipient mice (Figure 33).
The efficacy of the anti-Napi2B antibody-drug conjugates (ADCs) was investigated in a mouse xenograft model of Igrov-1 (human ovarian cancer).

Female C.B-17 SCID-beige mice (Charles River Laboratories; San Diego, CA) were each inoculated in the thoracic mammary fat pad area with 5 million Igrov-1 cells. When the xenograft tumors reached an average tumor volume of 100-300 mm³ (referred to as Day 0), animals were randomized into groups of 7-10 mice each and received a single intravenous injection of the ADCs. Tumors and body weights of mice were measured 1-2 times a week throughout the study. Mice were promptly euthanized when body weight loss was >20% of their starting weight. All animals were euthanized before tumors reached 3000 mm³ or showed signs of impending ulceration.

The efficacy of the anti-CD33 antibody-drug conjugates (ADCs) was investigated in a mouse xenograft model of HL-60 or EOL-1 (human acute myeloid leukemia). The HL-60 cell line was obtained from ATCC (American Type Culture Collection; Manassas, VA) and EOL-1 cell line was originated from DSMZ (German Collection of Microorganisms and Cell Cultures; Braunschweig, Germany).

Female C.B-17 SCID mice (Charles River Laboratories; Hollister, CA) were each inoculated subcutaneously in the flank area with five million cells of HL-60 or EOL-1. When the xenograft tumors reached an average tumor volume of 100-300 mm³ (referred to as Day 0), animals were randomized into groups of 7-10 mice each and received a single intravenous injection of the ADCs. Approximately 4 hours prior to administration of ADCs, animals were dosed intraperitoneally with excess amount (30mg/kg) of anti-gD control antibody to block possible nonspecific antibody binding sites on the tumor cells. Tumors and body weights of mice were measured 1-2 times a week throughout the study. Mice were promptly euthanized when body weight loss was >20% of their starting weight. All animals were euthanized before tumors reached 3000 mm³ or showed signs of impending ulceration.
Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, the descriptions and examples should not be construed as limiting the scope of the invention. All patents, patent applications, and references cited throughout the specification are expressly incorporated by reference.
