Title: ANTIBODIES THAT SPECIFICALLY BIND TO A BETA OLIGOMERS AND USE THEREOF

Abstract: The present inventors successfully produced monoclonal antibodies that are specific to only soluble A beta oligomers, but do not recognize soluble A beta monomers, which are physiological molecules. It was demonstrated that the antibodies are useful as diagnostic/therapeutic monoclonal antibodies for Alzheimer's disease.
Description

Title of Invention: ANTIBODIES THAT SPECIFICALLY BIND TO A BETA OLIGOMERS AND USE THEREOF

Technical Field

[0001] Priority
The present application claims the benefit of U.S. Provisional Application No. 61/231,797, filed on August 6, 2009, and U.S. Provisional Application No. 61/282,533, filed on February 26, 2010, the entire contents of which are incorporated by reference herein.

[0002] Technical Field
The present invention relates to antibodies that specifically bind to A beta oligomers and uses thereof.

Background Art

[0003] The number of Alzheimer's disease (AD) patients is more than about 26 million worldwide in 2006, and it is predicted to continue increasing in an aging society (Non-Patent Literature (NPL) 1). However, there is no curative therapeutic agent that arrests or reverses the progression of Alzheimer's disease, although therapeutic agents that retard the progression of the disease are commercially available.

[0004] Various evidence has shown that deterioration of memory arises from synaptic dysfunction triggered by soluble amyloid beta (A beta) oligomers (see Non-Patent Literatures 2 and 3). Excessive accumulation and deposition of A beta oligomers may be the trigger for a series of pathological cascades that lead to Alzheimer's disease. Therefore, therapeutic intervention targeting A beta oligomers may be effective for blocking these cascades (see Non-Patent Literatures 4 and 5).

[0005] Recently, antibody pharmaceuticals that target A beta are being developed. However, previously-reported anti-A beta oligomer antibodies do not specifically bind to A beta oligomers, but bind to all of the three forms, i.e., A beta monomers, oligomers, and fibrils. Thus, even if they are administered in vivo, it is thought that the amount of antibodies that bind to A beta oligomers would be relatively low, and the dosage may need to be increased to obtain effect. Moreover, since A beta monomers are present in the brain of healthy individuals, side effects may be cause by the binding of the antibodies to A beta monomers.

[0006] Furthermore, the amount of A beta oligomer could be an index of Alzheimer's disease; however, it was difficult to measure A beta oligomers alone using conventional anti-A beta antibodies.

Summary of Invention
Technical Problem

[0009] The present invention was achieved in view of the above circumstances. An objective of the present invention is to provide antibodies that bind specifically to A beta oligomers, and uses thereof. More specifically, the present invention provides antibodies that bind specifically to A beta oligomers, methods for detecting A beta oligomers using the antibodies, methods for diagnosing Alzheimer's disease using the antibodies, pharmaceutical compositions and agents comprising the antibodies, agents and kits for detecting A beta oligomers, and agents and kits for diagnosing Alzheimer's disease.

Solution to Problem

[0010] The present inventors successfully produced multiple monoclonal antibodies that are specific to only soluble amyloid beta (A beta) oligomers and do not recognize soluble A beta monomers which are physiological molecules, using an isolated A beta tetramer as an antigen.

[0011] Thus, the present inventors disclose that the multiple antibodies are promising candidates for therapeutic antibodies for treating/preventing Alzheimer's disease, or for diagnostic antibodies for diagnosing Alzheimer's disease.

[0012] More specifically, the present invention provides the following:

Description of Embodiments

The present invention will be described more specifically below.

As described above, the present inventors succeeded in obtaining antibodies that bind specifically to A beta oligomers but not to A beta monomers. That is, the present invention provides antibodies that bind to A beta oligomers but not to A beta monomers. Furthermore, the present invention provides antibodies that bind to A beta oligomers but not to A beta monomers and amyloid precursor protein (APP). The antibodies are preferably isolated or purified.

The terms "isolated" and "purified" used for substances (antibodies and such) of the present invention indicate that the substances do not substantially include at least one other substance that may be contained in the natural source. Therefore, "isolated an-
antibodies" and "purified antibodies" refer to antibodies that do not substantially include cell materials such as hydrocarbons, lipids, or other contaminant proteins from the cell or tissue source from which the antibodies (proteins) are derived. When the antibodies are chemically synthesized, the terms refer to antibodies that do not substantially include chemical precursor substances or other chemical substances. In a preferred embodiment, the antibodies of the present invention are isolated or purified.

"Antibodies" refers to glycoproteins that have the same structural characteristics. Antibodies show binding specificity towards specific antigens. Herein, "antigens" refers to proteins that have the ability to bind to the corresponding antibodies, and induce antigen-antibody reactions in vivo.

Herein, the antibody heavy chain may be denoted as "H chain", the antibody light chain may be denoted as "L chain", the heavy chain variable region may be denoted as "VH", the light chain variable region may be denoted as "VL", the heavy chain constant region may be denoted as "CH", the light chain constant region may be denoted as "CL", the framework region may be denoted as "FR", and the complementarity-determining region may be denoted as "CDR".

A beta proteins, which are the major constituents of amyloids, are peptides consisting of 40 to 42 amino acids, and are known to be produced from precursor proteins called amyloid precursor proteins (APPs) by the action of proteases. Besides amyloid fibrils collected in ultracentrifuged sediment fractions, the amyloid molecules produced from APPs include oligomeric non-fibrous assemblies in addition to soluble monomers. "A beta oligomers" of the present invention refer to non-fibrous assemblies. The degree of A beta polymerization of "A beta oligomer" of the present invention is not particularly limited, but is typically 2 to 150. The "A beta oligomers" of the present invention include, for example, A beta40 (A beta 1-40) oligomers, A beta42 (A beta 1-42) oligomers, and A beta40/A beta42 oligomers (in which A beta40 and A beta42 are polymerized). For example, "A beta oligomers" of the present invention are, typically, molecules showing a molecular weight of 45 to 160 kDa in SDS-PAGE, and 22.5 to 1,035 kDa in Blue Native PAGE. Using molecular sieves, the molecules are collected mainly in the >100 kDa retention solution. When observed under an atomic force microscope, the molecules show mixed morphologies of granular, bead-shaped, and ring-shaped molecules having a height of 1.5 to 3.1 nm.

There is no limitation on the origin and form of the antibodies used in the present invention as long as they bind to A beta oligomers but not to A beta monomers, or they bind to A beta oligomers but not to A beta monomers and amyloid precursor protein.

The antibodies of the present invention are featured by the characteristics that they bind to A beta oligomers but not to A beta monomers, or they bind to A beta oligomers but not to A beta monomers and amyloid precursor protein. Preferably, these an-

In immunoblot analysis, they do not react with human amyloid precursor protein.

[0023] The antibodies of the present invention may be featured by at least one of the above characteristics. Furthermore, the antibodies may be featured by two or more of the above characteristics.

[0024] "Antibodies" of the present invention include both monoclonal and polyclonal antibodies. The antibodies of the present invention also include any type of antibodies such as non-human animal antibodies, humanized antibodies, chimeric antibodies, human antibodies, the later-described minibodies, amino acid sequence-modified antibodies, modified antibodies conjugated to other molecules (for example, polymers such as polyethylene glycol), and sugar chain-modified antibodies.
Herein, the term "monoclonal antibodies" refers to antibodies that are obtained from a substantially homogeneous population of antibodies. That is, the individual antibodies constituting the population are identical with the exception of possible natural mutants that may be present in a trace amount. Monoclonal antibodies are highly specific and recognize a single antigenic site. Each of the monoclonal antibodies recognizes a single determinant of the antigen, in contrast to conventional (polyclonal) antibody preparations that typically contain different antibodies against different antigenic determinants (epitopes).

In addition to the above-mentioned specificity, monoclonal antibodies have the advantage that they can be synthesized from a hybridoma culture that is not contaminated with other immunoglobulins. Therefore, "monoclonal" indicates the characteristics of antibodies that can be obtained from a substantially homogeneous antibody population. This term does not indicate the requirement for any specific method for antibody production.

Basically, monoclonal antibodies can be produced by using known techniques. For example, they may be produced by the hybridoma method first described by Kohler and Milstein (Nature 256: 495-7, 1975), or by the recombinant DNA method (Cabilly et al., Proc. Natl. Acad. Sci. USA 81:3273-7, 1984), but the methods are not limited thereto. For example, when using the hybridoma method, an A beta oligomer is used as a sensitizing antigen, and immunization is carried out according to a conventional immunization method. The obtained immune cells are fused with known parent cells by a conventional cell fusion method, and monoclonal antibody-producing cells can be screened and isolated using a conventional screening method.

The monoclonal antibodies of the present invention can be produced, for example, as follows. First, synthetic A beta 1-42 (Peptide Institute, Inc., Osaka) is dissolved in distilled deionized water or a 10 mM phosphate buffer solution, and this is incubated at 37 degrees C for 18 hours. Then, the peptides are separated by 4-12% SDS-PAGE, and visualized by CBB staining, and the portion of the A beta 1-42 tetramer alone which is not contaminated with the A beta 1-42 monomer is cut out. Next, BALB/c mice are immunized at their foot pad with 2.5 micro g of the A beta 1-42 tetramer emulsified using complete Freund's adjuvant. Subsequently, booster immunizations are carried out six times. Hybridomas are produced from the inguinal lymph node by fusion with Sp2/O-Agl4 cells using Polyethylene Glycol 1500.

In the present invention, the animals immunized with sensitizing antigens are not particularly limited, but are preferably selected considering the compatibility with parent cells used for cell fusion. Generally, rodents, lagomorphs, or primates are used. Rodents include, for example, mice, rats, and hamsters. Lagomorphs include, for example, rabbits. Primates include, for example, Catarrhini (old-world) monkeys such
as Macaca fascicularis, Macaca mulatta, hamadryas, and chimpanzees.

Animals are immunized with sensitizing antigens according to known methods. For example, as a standard method, immunization is performed by intraperitoneal or subcutaneous injection of a sensitizing antigen into mammals.

An example of the parent cells fused with the aforementioned immunocytes is the Sp2/O-Ag14 cell, which will be described below in the Examples. However, various other known cell lines can be used.

Cell fusion between the aforementioned immunocyte and a myeloma cell can be carried out basically according to known methods including the method by Kohler and Milstein (Kohler G. and Milstein C., Methods Enzymol. (1981) 73, 3-46).

Hybridomas obtained in this manner are selected by culturing them in a conventional selection culture medium such as a HAT culture medium, which contains hypoxanthine, aminopterin, and thymidine. Culturing in the above-mentioned HAT culture medium is generally continued for several days to several weeks for an adequate time for killing cells other than the desired hybridomas (non-fused cells).

Next, a conventional limiting dilution method is performed for screening and singly-cloning of a hybridoma that produces the desired antibody.

Thereafter, the obtained hybridoma is transplanted into the abdominal cavity of a mouse, and ascitic fluid containing the desired monoclonal antibodies is extracted. For example, the antibodies can be purified from the ascitic fluid by conventional protein separation and/or purification methods such as a selected combination of column chromatography including, but not limited to, affinity chromatography, filtration, ultra-filtration, salt precipitation, dialysis, SDS polyacrylamide gel electrophoresis, and isoelectric focusing (Antibodies: A Laboratory manual, Harlow and David, Lane (edit.), Cold Spring Harbor Laboratory, 1988).

Protein A columns and Protein G columns can be used for affinity columns. Examples of the Protein A columns used include Hyper D, POROS, and Sepharose F.F. (Pharmacia).

Chromatography (excluding affinity chromatography) includes ion exchange chromatography, hydrophobic chromatography, gel filtration, reverse-phase chromatography, and adsorption chromatography ("Strategies for Protein Purification and Characterization: A Laboratory Course Manual", Daniel R Marshak et al., Cold Spring Harbor Laboratory Press, 1996). When chromatography is carried out, liquid-phase chromatography methods such as HPLC and FPLC can be used.

Monoclonal antibody-producing hybridomas prepared in this manner can be subcultured in a conventional culture medium, and they can be stored for a long time in liquid nitrogen.

Any mammal can be immunized using an immunogen for antibody production.
However, when preparing monoclonal antibodies by producing hybridomas, the compatibility with parent cells used in cell fusion for hybridoma production is preferably considered.

[0039] Generally, rodents, lagomorphs, or primates are used for the immunization. Rodents include, for example, mice, rats, and hamsters. Lagomorphs include, for example, rabbits. Primates include, for example, Catarrhini (old-world) monkeys such as Macaca fascicularis, Macaca mulatta, hamadryas, and chimpanzees.

[0040] The use of transgenic animals that have a human antibody gene repertoire is known in the art (Ishida I, et al., Cloning and Stem Cells 4: 91-102, 2002). As with other animals, to obtain human monoclonal antibodies, the transgenic animals are immunized, then antibody-producing cells are collected from the animals and fused with myeloma cells to produce hybridomas, and anti-protein human antibodies can be prepared from these hybridomas (see International Publication Nos. WO92/03918, WO94/02602, WO94/25585, WO96/33735, and WO96/34096).

[0041] Alternatively, lymphocytes immortalized with oncogenes may be used for monoclonal antibody production. For example, human lymphocytes infected with EB virus or such is immunized in vitro with immunogens. Next, the immunized lymphocytes are fused with human-derived myeloma cells (U266, etc) capable of unlimited division, and thus hybridomas that produce the desired human antibodies are obtained (Japanese Patent Application Kokai Publication No. (JP-A) S63-17688 (unexamined, published Japanese patent application)).

[0042] Once monoclonal antibodies can be obtained by any of the aforementioned methods, the antibodies may also be prepared using genetic engineering methods (see, for example, Borrebaeck CAK and Larrick JW, Therapeutic Monoclonal Antibodies, MacMillan Publishers, UK, 1990). For example, recombinant antibodies may be prepared by cloning DNAs that encode the desired antibodies from antibody-producing cells such as hybridomas or immunized lymphocytes that produce the antibodies, then inserting the cloned DNAs into appropriate vectors, and transfecting the vectors into suitable host cells. Such recombinant antibodies are also included in the present invention.

[0189] In an embodiment, the antibodies of the present invention include minibodies. A minibody contains an antibody fragment lacking a portion of a whole antibody, and is not particularly limited as long as it has the ability to bind to an antigen. Examples of antibody fragments include Fab, Fab', F(\text{ab}')2, and Fv. Examples of minibodies include Fab, Fab', F(\text{ab}')2, Fv, scFv (single chain Fv), diabody, and sc(Fv)2 (single chain (Fv)2).

[0191] Herein, "antigen-binding fragments" means the above-mentioned antibody fragments having antigen-binding ability, or minibodies including the antibody fragments having antigen-binding ability. Antibody fragments that bind to A beta oligomers but not to A beta monomers, or antibody fragments that bind to A beta oligomers but not to A beta monomers and amyloid precursor protein, are also included in the present invention. Hereinafter, reference to "antibody" includes reference to the above "antigen-binding fragment".

[0192] Polyclonal antibodies of the present invention can be obtained by the following methods. To obtain the polyclonal antibodies, blood is removed from a mammal sensitized with an antigen after the mammal is immunized with an A beta oligomer (e.g., A beta tetramer) as a sensitizing antigen using a conventional method and the serum level of the desired antibody is confirmed to be increased. Serum is separated from blood by a known method. When a polyclonal antibody is used, serum containing the polyclonal antibody may be utilized. Alternatively, if necessary, a fraction containing the polyclonal antibody may be isolated from serum and then used. For example, immunoglobulin G or M can be prepared by obtaining a fraction that specifically recognizes an A beta oligomer using an affinity column coupled with an A beta oligomer, and then purifying this fraction using a Protein A or Protein G column.
The present invention provides A beta oligomers bound by the antibodies of the present invention. Preferably, the antibodies include the following:

The A beta oligomers can be used as antigens for preparing antibodies, or vaccines.

In other words, in the present invention, the A beta oligomers are antigens bound by the following antibodies:

Furthermore, the antibodies of the present invention include antibodies that bind to the antigens bound by the following antibodies:

[0198] As mentioned above, "CDR1, CDR2, and CDR3" refers to CDR determined by a method well-known in the art (e.g., see Kabat, Elvin A., Sequences of proteins of immunological interest 5th ed., National Institutes of Health, 1991; Chothia et al, J Mol Biol 196:901-917,1987). It is a technical common knowledge in the art that the amino acid sequences of CDR1, CDR2, and CDR3 can be identified in amino acid sequences of regions including CDR1, CDR2, and CDR3, using a method well-known in the art. In the following embodiments, for each antibody, an example of the CDR amino acid sequence determined according to the definition by Kabat is shown.

[0491] The above-mentioned H chains, L chains, VHs, and VLs can be used to prepare the antibodies of the present invention. The present invention also relates to the above-mentioned H chains, L chains, VHs, and VLs.

[0492] The above-mentioned antibodies of (1) to (872) include not only monovalent antibodies but also multivalent antibodies with two or more valencies. [0493] In a preferred embodiment, the above-mentioned antibody of (871) is an antibody with no modified CDRs. For example, the "antibody that comprises one or more amino acid substitutions, deletions, additions, and/or insertions in the antibody of (1), which has equivalent activity as the antibody of (1)" of the above-mentioned antibody of (871) is preferably "an antibody that has equivalent activity as the antibody of (1), and comprises one or more amino acid substitutions, deletions, additions, and/or insertions in the antibody of (1), and comprises an H chain having the amino acid sequence of SEQ ID NO: 6 as CDR1, the amino acid sequence of SEQ ID NO: 8 as CDR2, and the amino acid sequence of SEQ ID NO: 10 as CDR3". ID NO: b as CDR2, and the amino acid sequence of SEQ ID NO: c as CDR3, and an L
chain having the amino acid sequence of SEQ ID NO: d as CDR1, the amino acid
sequence of SEQ ID NO: e as CDR2, and the amino acid sequence of SEQ ID NO: f as
CDR3, wherein the "antibody that has equivalent activity" comprises:
an H chain having:
as CDR1, the amino acid sequence of SEQ ID NO: a, or an amino acid sequence with
one or several amino acid substitutions, deletions, additions and/or insertions in the

as CDR3, the amino acid sequence of SEQ ID NO: f, or an amino acid sequence with

can be expressed as follows:

an antibody that has equivalent activity as an antibody comprising an H chain having VH comprising the amino acid sequence of SEQ ID NO: g, wherein the "antibody that has equivalent activity" comprises an H chain having VH comprising an amino acid sequence in which one or several amino acids are substituted, deleted, added, and/or inserted in the amino acid sequence of SEQ ID NO: g;

an antibody that has equivalent activity as an antibody comprising an L chain having VL comprising the amino acid sequence of SEQ ID NO: h, wherein the "antibody that has equivalent activity" comprises an H chain having VL comprising an amino acid sequence in which one or several amino acids are substituted, deleted, added, and/or inserted in the amino acid sequence of SEQ ID NO: h;

or

an antibody that has equivalent activity as an antibody comprising an H chain having VH comprising the amino acid sequence of SEQ ID NO: g and an L chain having VL comprising the amino acid sequence of SEQ ID NO: h, wherein the "antibody that has equivalent activity" comprises

[0501] The antibody of (871) for each of the above antibodies can be expressed by referring to the amino acid SEQ ID NO of VH for "g" above, and the amino acid SEQ ID NO of VL for "h" above. For example, the antibody of (871) for an antibody having equivalent activity as an antibody that has the VH and/or VL chain of the IR-001 antibody can be expressed as follows:

can be expressed as follows:

an antibody that has equivalent activity as an antibody comprising an H chain having

The antibody of (871) for each of the above antibodies can be expressed by referring to the amino acid SEQ ID NO of VH for "a" above, the amino acid SEQ ID NO of H chain CDR1 for "b" above, the amino acid SEQ ID NO of H chain CDR2 for "c" above, the amino acid SEQ ID NO of H chain CDR3 for "d" above, the amino acid SEQ ID NO of VL for "e" above, the amino acid SEQ ID NO of L chain CDR1 for "f" above, the amino acid SEQ ID NO of L chain CDR2 for "g" above, the amino acid SEQ ID NO of L chain CDR3 for "h" above. the IR-001, IR-002, IR-004, IR-005, IR-006, IR-007, IR-008, IR-011, IR-012, IR-013, IR-014, IR-015, IR-017, IR-020, IR-021, IR-022, IR-023, IR-024, IR-025, IR-026, IR-027, IR-028, IR-029, IR-030, IR-031, IR-032, IR-033, IR-034, IR-035, IR-036, IR-037, IR-038, IR-039, IR-040, IR-041, IR-043, IR-044, IR-045, IR-046, IR-048, IR-049, IR-050, IR-051, IR-052, IR-053, IR-054, IR-055, IR-056, IR-057, IR-058, IR-059, IR-060, IR-061, IR-062, IR-063, IR-064, IR-065, IR-066, IR-067, IR-068, IR-069, IR-070, IR-071, IR-072, IR-073, IR-074, IR-075, IR-076, IR-077, IR-
the amino acid modifications are preferably conserved amino acid substitutions, as described below in detail. Thus, in a more preferred embodiment, in the antibodies of (871) described above, "conservative amino acid substitution" can be performed, instead of "substitution, deletion, addition, and/or insertion".

Methods for preparing a polypeptide having activity equivalent to that of a certain polypeptide that are well known to those skilled in the art include methods for introducing mutations into a polypeptide. For example, one skilled in the art can prepare an antibody having activity equivalent to that of an antibody of the present invention by introducing appropriate mutations into the antibody using site-directed mutagenesis (Hashimoto-Gotoh, T. et al. (1995) Gene 152, 271-275; Zoller, MJ, and Smith, M. (1983) Methods Enzymol. 100, 468-500; Kramer, W. et al. (1984) Nucleic Acids Res. 12, 9441-9456; Kramer W, and Fritz HJ (1987) Methods. Enzymol. 154, 350-367; Kunkel, TA (1985) Proc. Natl. Acad. Sci. USA. 82, 488-492; Kunkel (1988) Methods Enzymol. 85, 2763-2766) and such. Amino acid mutations may also occur naturally. The antibodies of the present invention also include an antibody that comprises an amino acid sequence with one or more amino acid mutations in the amino acid sequence of an antibody of the present invention, and which has activity equivalent to that of the antibody of the present invention.

Amino acid residues are preferably mutated into other amino acids that conserve the properties of the amino acid side chains. For example, amino acids are categorized as follows depending on the side chain properties: hydrophobic amino acids (A, I, L, M, F, P, W, Y, and V), hydrophilic amino acids (R, D, N, C, E, Q, G, H, K, S, and T), amino acids with aliphatic side chains (G, A, V, L, I, and P), amino acids with hydroxyl-containing side chains (S, T, and Y), amino acids with sulfur atom-containing side chains (C and M), amino acids with carboxylic acid- and amide-containing side chains (D, N, E, and Q), amino acids with basic side chains (R, K, and H), and amino acids with aromatic ring-containing side chains (H, F, Y, and W) (amino acids are represented by one-letter codes in parentheses). "Conservative amino acid substitution" refers to substitution of an amino acid with another amino acid with a conserved amino acid side chain characteristics. In the antibodies of (871), amino
acid sequence mutations in an antibody are preferably "conservative amino acid substitutions".

[0508] Generally, a polypeptide having an amino acid sequence, in which one or more amino acid residues are modified (deleted, added, and/or substituted with other amino acids) in a certain amino acid sequence, is known to retain its original biological activity (function).

[0509] In addition to the above-mentioned modifications, the antibodies of the present invention may be conjugated to other substances as long as the activity is maintained. Examples of the substances include peptides, lipids, sugars and sugar chains, acetyl groups, and natural and synthetic polymers. These modifications may be performed to confer additional functions to the antibodies, or to stabilize the antibodies.

[0510] Antibodies in which several amino acid residues have been added to the amino acid sequence of an antibody of the present invention include fusion proteins containing the antibody. In the fusion proteins, the antibody is fused with another peptide or protein. Methods for producing a fusion protein can be carried out by ligating a polynucleotide encoding an antibody of the present invention in frame with a polynucleotide encoding another peptide or polypeptide, and inserting this into an expression vector, and expressing the fusion construct in a host. Techniques known to those skilled in the art can be used for this purpose. The peptides or polypeptides fused with an antibody of the present invention include, for example, known peptides such as FLAG (Hopp, T.P. et al., BioTechnology (1988) 6, 1204-1210), 6x His consisting of six histidine (His) residues, 10x His, Influenza hemagglutinin (HA), human c-myc fragments, VSV-GP fragments, p18HIV fragments, T7-tag, HSV-tag, E-tag, SV40T antigen fragments, lck tag, alpha-tubulin fragments, B-tag, and Protein C fragments; glutathione-S-transferase (GST); immunoglobulin constant regions; beta-galactosidase; and maltose-binding protein (MBP), etc. Commercially available polynucleotides encoding these peptides or polypeptides can be fused with polynucleotides encoding the antibodies of the present invention, and the fusion polypeptides can be produced by expressing the fusion polynucleotides thus prepared.

[0511] The antibodies of the present invention may differ in the amino acid sequence, molecular weight, presence or absence of sugar chains, structure and such, depending on the cell or host producing the antibodies or the purification method. However, as long as the obtained antibody has an activity equivalent to an antibody of the present invention, it is included in the present invention.

[0512] Herein, "equivalent activity" means that the antibody of interest has the same biological or biochemical activity as an antibody of the present invention. The "activity" of the present invention includes, for example, activity to specifically bind to A beta oligomers but not bind to A beta monomers, activity to specifically bind to A beta
oligomers but not bind to A beta monomers and amyloid precursor protein, anti-neurotoxic activity, A beta amyloid fibril formation suppressing activity, anti-synaptic toxicity activity, anti-memory impairment activity, anti-A beta deposition activity, anti-thioflavin S-positive plaque formation activity, and anti-A beta oligomer accumulation activity.

[0513] In a preferred embodiment, the "activity" of the present invention is activity to specifically bind to A beta oligomers but not bind to A beta monomers. As shown in the Example, the "activity to specifically bind to A beta oligomers but not bind to A beta monomer" is preferably assessed by dot blot or competitive ELISA. Specific methods of dot blot or competitive ELISA include methods described in the Examples. Furthermore, the binding activity towards A beta oligomers and monomers can be assessed by other immunodetection methods, for example, absorbance measurement, enzyme-linked immunosorbent assay (ELISA), enzyme immunoassay (EIA), radioimmunoassay (RIA), immunofluorescent method, etc. For example, in ELISA, an antibody is immobilized onto a plate, an antigen for the antibody is added to the plate, and a culture supernatant of antibody-producing cells or a purified antibody is added. Then, a secondary antibody that recognizes a primary antibody and that is tagged with an enzyme such as alkaline phosphatase is added, and the plate is incubated. After washing, an enzyme substrate such as p-nitrophenyl phosphate is added to the plate, and the absorbance is measured to assess the antigen-binding ability of a sample of interest. The binding abilities for A beta oligomers and monomers are preferably measured by the same method; however, they can be measured by different methods. For example, the binding to A beta oligomers can be analysed using Biacore (GE Healthcare Sciences).

[0514] When the "activity" of the present invention is the activity to specifically bind to A beta oligomers but not bind to A beta monomers and amyloid precursor protein, the activity can be assessed by the above-mentioned methods or methods described in the Examples.

When the "activity" of the present invention is anti-neurotoxic activity, this activity can be assessed by, for example, culturing neurons with A beta in the presence or absence of an antibody, and measuring the A beta-induced cytotoxicity level inhibited by the antibody. A beta-induced cytotoxicity can be measured by, for example, live/dead two color fluorescent assay, measurement of the LDH amount derived from dead cells released into a medium. For the measurement of the LDH amount, for example, CytoTox96 (Promega) or such can be used. Specific methods for measuring anti-neurotoxic activity include the methods described in the Examples.

[0515] When the "activity" of the present invention is A beta amyloid fibril formation suppressing activity, this activity can be assessed, for example, by incubating an A beta
solution with or without an antibody, and detecting the A beta amyloid fibril formation level suppressed by the antibody. The amount of A beta amyloid fibril is assessed, for example, by adding a ThT (Thioflavin T) solution to a culture, and the amount of ThT bound to amyloid fibrils with ThT fluorescence. Specific methods for measuring A beta amyloid fibril formation suppressing activity include the methods described in the Examples.

When the "activity" of the present invention is anti-synaptic toxicity activity, this activity can be assessed, for example, by detecting synaptic toxicity suppressing effect by antibody administration to mutant human APP gene-expressing mice (for example, Tg2576 mice, Taconics, USA). The assessment of synaptic toxicity can be performed by mouse memory impairment test, analysis of the number of swollen dystrophic neurites using an anti-synaptophycin antibody, immunofluorescent analysis of mouse brain sections using anti-synaptophysin or anti-drebrin antibodies. When the "activity" of the present invention is anti-memory impairment activity, this activity is assessed by memory impairment test using mutant APP gene-expressing mice. If the "activity" of the present invention is anti-A beta deposition activity, anti-thioflavin S-positive plaque formation activity, or anti-A beta oligomer accumulation activity, these activities can be assessed by antibody administration test using mutant APP gene-expressing mice.

Specific methods for measuring the anti-memory impairment activity, anti-synaptic toxicity activity, anti-A beta deposition activity, anti-thioflavin S-positive plaque formation activity, and anti-A beta oligomer accumulation activity include the following method.

Female non-transgenic (non-Tg) mice for control, and Tg2576 mice having and over-expressing the Swedish-type mutant human APP gene with dual mutations (K670N and M671L) derived from familial AD are administered with the antibody of the present invention (dosage within the range of 0.4 to 5.0 mg/kg/w) or PBS into the caudal vein. The mouse age at the initiation of administration is six months or later at which memory and learning impairments are expressed, for monitoring therapeutic effect; or four months for monitoring prophylactic effect. Antibody administration period is two months for monitoring therapeutic effect, and nine months for monitoring prophylactic effect. To measure the anti-memory impairment activity, the following three behavioral paradigms are analysed after the antibody administration period (Mouri A, FASEB J, 21: 2135-2148, 2007): (1) Y-maze test for short-term memory; (2) novel object recognition test; (3) contextual fear conditioning test. To assess the other activities, mice are sacrificed after the behavioral analysis, and the brain hemispheres are sliced into 10 to 30-micro m-thick sagittal sections using a cryotome (RM 2145; Leica, Wetzlar, Germany). To observe thioflavin S-positive plaque
The formation of swollen dystrophic neurites is observed using an anti-synaptophysin antibody (Chemicon, Temecula, CA). For each mouse, the number of thioflavin S-positive plaques and synaptophysin-positive swollen dystrophic neurites are calculated in four or five sections from a brain hemisphere at 40-fold magnification. To observe A beta deposition, serial sections briefly pre-treated with formic acid or Protease K are stained using an A beta immunostaining kit (Sigma, St. Louis, MO) or anti-A beta polyclonal antibody (Biosource), and immuno-positive signals are visualized using an ABC elite kit (Vector Laboratories). Images of the cerebral cortex and hippocampus are recorded using a digital camera connected with a microscope, and analyzed using a simple PCI software (Compix Imaging System, Lake Oswego, OR). The number of thioflavin S-positive plaques and synaptophysin-positive swollen dystrophic neurites was determined in a double blind manner. Synaptic degeneration is observed by immunostaining using anti-synaptophysin or anti-drebrin antibodies. To assess the anti-A beta oligomer deposition activity, brain homogenates are prepared from the other brain hemisphere of the same mouse using the method by Kawarabayashi et al., J. Neuroscience 2001), and the amount of A beta oligomers is measured by SDS-PAGE and immunoblot analysis. For detection antibodies, commercially available anti-A beta oligomer monoclonal antibodies (e.g., 6E10, Covance Immuno-Technologies, Dedham, MA) or polyclonal antibodies (e.g., All, Biosource, Carmarillo, CA) can be used.

The term "equivalent" in "equivalent activity" means that a value obtained as a biological or biochemical activity differs within 20% between two antibodies compared. The difference of the activity value is, preferably within 15%, within 10%, within 5%, or within 2.5%.

Antibodies that bind to an epitope to which an antibody of any one of (1) to (870) above binds can be obtained by methods known to those skilled in the art. For example, the antibodies can be obtained by (i) determining the epitope bound by the antibody of any one of (1) to (870) using a conventional method, and producing the antibodies using a polypeptide comprising an amino acid sequence included in the epitope as an immunogen; or (ii) determining the epitopes of antibodies produced by a conventional method, and selecting antibodies whose epitope is the same as that of the antibody of any one of (1) to (870).

The above-mentioned antibodies of (1) to (870) also include any type of antibodies such as the above-described minibodies, antibodies with modified amino acid sequences such as humanized antibodies and chimeric antibodies, non-human animal antibodies, human antibodies, modified antibodies conjugated to other molecules (for example, polymers such as polyethylene glycol), and sugar chain-modified antibodies.

and FR derived from human immunoglobulin, and a constant region derived from
human immunoglobulin.

[0524] The above chimeric antibodies can be expressed as follows:
an antibody that comprises an H chain having VH comprising the amino acid
sequence of SEQ ID NO: a, and CH of a human antibody;
an antibody that comprises an L chain having VL comprising the amino acid
sequence of SEQ ID NO: b, and CL of a human antibody; or
an antibody that comprises an H chain having VH comprising the amino acid
sequence of SEQ ID NO: a, and CH of a human antibody, and an L chain having VL
comprising the amino acid sequence of SEQ ID NO: b, and CL of a human antibody.

[0525] Preferred embodiments of chimeric antibodies from each of the above antibodies can
be expressed by referring to the amino acid SEQ ID NO of VH for "a" above, and the
amino acid SEQ ID NO of VL for "b" above. For example, chimeric antibodies for the
IR-001 antibody can be expressed as follows:
an antibody that comprises an H chain having VH comprising the amino acid
sequence of SEQ ID NO: 2290, and CH of a human antibody;
an antibody that comprises an L chain having VL comprising the amino acid
sequence of SEQ ID NO: 2292, and CL of a human antibody; or
an antibody that comprises an H chain having VH comprising the amino acid
sequence of SEQ ID NO: 2290, and CH of a human antibody, and an L chain having
VL comprising the amino acid sequence of SEQ ID NO: 2292, and CL of a human
antibody.
The above humanized antibodies can be expressed as follows:

an antibody that comprises an H chain having CDR of VH comprising the amino acid sequence of SEQ ID NO: a, FR of VH of a human antibody, and CH of a human antibody;

an antibody that comprises an L chain having CDR of VL comprising the amino acid sequence of SEQ ID NO: b, FR of VL of a human antibody, and CL of a human antibody; or

an antibody that comprises an H chain having CDR of VH comprising the amino acid sequence of SEQ ID NO: a, FR of VH of a human antibody, and CH of a human antibody, and an L chain having CDR of VL comprising the amino acid sequence of SEQ ID NO: b, FR of VL of a human antibody, and CL of a human antibody.

Preferred embodiments of humanized antibodies from each of the above antibodies can be expressed by referring to the amino acid SEQ ID NO of VH for "a" above, and the amino acid SEQ ID NO of VL for "b" above. For example, humanized antibodies for the IR-001 antibody can be expressed as follows:

an antibody that comprises an H chain having CDR of VH comprising the amino acid sequence of SEQ ID NO: 2290, FR of VH of a human antibody, and CH of a human antibody;

an antibody that comprises an L chain having CDR of VL comprising the amino acid sequence of SEQ ID NO: 2292, FR of VL of a human antibody, and CL of a human antibody; or

an antibody that comprises an H chain having CDR of VH comprising the amino acid sequence of SEQ ID NO: 2290, FR of VH of a human antibody, and CH of a human antibody, and an L chain having CDR of VL comprising the amino acid sequence of SEQ ID NO: 2292, FR of VL of a human antibody, and CL of a human antibody.

The above modified antibodies can be produced using known methods.

Since the antigenicity of a chimeric antibody or a humanized antibody in the human body is reduced, such an antibody is useful for administration to humans for therapeutic purposes or such.

Chimeric antibodies are produced by combining sequences derived from different animals. Examples of chimeric antibodies include antibodies comprising the heavy-chain and light-chain variable regions of a mouse antibody and the heavy-chain and light-chain constant regions of a human antibody. The production of chimeric antibodies can be carried out using known methods (see, for example, Jones et al., Nature 321:522-5, 1986; Riechmann et al., Nature 332:323-7, 1988; and Presta, Curr. Opin. Struct. Biol. 2:593-6, 1992). For example, first, genes encoding the variable regions or CDRs of the antibody of interest are prepared from the RNAs of antibody-producing cells by polymerase chain reaction (PCR) or such (see, for example, Larrick et al.,
"Methods: a Companion to Methods in Enzymology", Vol. 2: 106, 1991; Courtenay-Luck, "Genetic Manipulation of Monoclonal Antibodies" in Monoclonal Antibodies: Production, Engineering and Clinical Application; Ritter et al. (eds.), page 166, Cambridge University Press, 1995, and Ward et al., "Genetic Manipulation and Expression of Antibodies" in Monoclonal Antibodies: Principles and Applications; and Birch et al. (eds.), page 137, Wiley-Liss, Inc., 1995). To prepare chimeric antibodies from any one of the AL-201 to AL-333 antibodies, a gene encoding a variable region or CDR can be synthesized based on the sequence information of each of the antibodies disclosed herein. The prepared genes encoding the variable regions or CDRs are linked to genes encoding the constant regions (e.g., human antibody constant regions) or framework regions (e.g., human antibody framework regions). The genes encoding the constant regions or framework regions may be determined in a manner similar to that for the variable region-encoding or CDR-encoding genes, or alternatively, they can be prepared based on the sequence information of known antibodies. DNA sequences encoding chimeric products and CDR-grafted products may be synthesized completely or partially using oligonucleotide synthesis techniques. For example, the oligonucleotide synthesis described by Jones et al. (Nature 321:522-5, 1986) may be performed. Furthermore, in some cases, site-directed mutagenesis and polymerase chain reaction techniques may be appropriately used. Techniques for oligonucleotide-specific mutagenesis of known variable regions described by Verhoeyen et al. (Science 239: 1534-6, 1988) and Riechmann et al. (Nature 332: 323-7, 1988) may be used for modifying the variable region sequences, for example, to enhance the binding ability of chimeric antibodies. Furthermore, if necessary, enzymatic fill-in of gapped oligonucleotides using T4 DNA polymerase may be performed, for example, as described by Queen et al. (Proc. Natl. Acad. Sci. USA 86: 10029-33, 1989; and WO 90/07861). [0531] For example, CDR-grafting techniques are known in the art ("Immunoglobulin genes", Academic Press (London), pp 260-74, 1989; and Michael A et al., Proc. Natl. Acad. Sci. USA 91: 969-73, 1994). Using the techniques, the CDRs of a certain antibody are replaced with the CDRs of another antibody. Through such replacement, the binding specificity of the former antibody is changed to that of the latter antibody. Among such chimeric antibodies, those in which the framework amino acids are derived from a human antibody are called "humanized antibodies (CDR-grafted antibodies)". When using antibodies to treat humans, human antibodies or humanized antibodies are preferably utilized. [0532] Generally, chimeric antibodies comprise the variable regions of a non-human mammal-derived antibody and the constant regions derived from a human antibody. On the other hand, humanized antibodies comprise the complementarity-determining
regions (CDR) of a non-human mammal-derived antibody and the framework regions and constant regions derived from a human antibody.

[0533] After producing the chimeric antibodies or humanized antibodies, amino acids in the variable regions (for example, FRs) or the constant regions may be substituted with other amino acids.

[0534] The origin of the variable regions of the chimeric antibodies or the CDRs of the humanized antibodies is not particularly limited.

[0535] Human antibody-derived C-regions are used for the C-regions of the chimeric antibodies and humanized antibodies. For example, C gamma, C gamma2, C gamma3, C gamma4, C mu, C delta, C alpha 1, C alpha2, and C epsilon can be used for the H-chain C-regions, and C kappa and C lambda can be used for the L-chain C-regions. Their sequences are known. Furthermore, the human antibody C regions can be modified to improve the stability of the antibodies or their production.

[0536] The present invention provides polynucleotides encoding the above antibodies of the present invention or antigen-binding fragments thereof.

[0537] The polynucleotides of the present invention are not particularly limited as long as they encode the antibodies of the present invention, and may be a DNA or RNA. Furthermore, they may include a non-natural base. The polynucleotides of the present invention can be used for producing the antibodies of the present invention by genetic engineering techniques.

[0538] The polynucleotides of the present invention can be obtained by isolating mRNA from antibody-producing cells that produce an antibody of the present invention, obtaining cDNA by reverse transcription reaction, and amplifying the obtained cDNA by PCR or such, as described in the Examples.

[0541] In the above embodiments, the polynucleotides can be obtained by synthesizing the
polynucleotides based on the amino acid sequence information of each of the above
antibodies described herein.

[0542] Furthermore, the present invention provides vectors comprising the polynucleotides
of the present invention. The vectors of the present invention are preferably expression
vectors for expressing an antibody of the present invention in a host cell. The vectors
of the present invention may be used for producing the antibodies of the present
invention.

[0543] The vectors of the present invention preferably comprise a promoter sequence that
enables expression in a host cell, in addition to a polypeptide of the present invention.
Furthermore, they may comprise a signal sequence for secretion of an antibody of the
present invention. Furthermore, they may comprise a marker gene for selection of a
host cell into which a vector of the present invention has been introduced. The
components comprised in the vectors are not limited thereto, and may be a suitable
component appropriately selected by those skilled in the art.

[0544] For example, expression vectors for expression in E. coli include vectors that have
"ori" for amplification in E. coli, and have a promoter such as lacZ promoter (Ward et al., Nature (1989) 341, 544-546; FASEB J. (1992) 6, 2422-2427), araB promoter (Better et al., Science (1988) 240, 1041-1043), or T7 promoter, and a marker gene such as a drug-resistance gene against ampicillin, tetracycline, kanamycin, chloramphenicol, etc. The vectors include M13 vectors, pUC vectors, pBR322, pBluescript, pCR-Script, etc. Furthermore, for a signal sequence, the pelB signal sequence (Lei, S. P. et al J. Bacteriol. (1987) 169, 4379) or such can be used.

[0545] The vectors of the present invention other than E. coli expression vectors include, for example, mammal-derived expression vectors (e.g., pcDNA3 (Invitrogen), pEGF-BOS (Nucleic Acids. Res. 1990, 18(17), p5322), pEF, pCDM8), insect cell-derived expression vectors (e.g, Bac-to-BAC baculovirus expression system (Gibco BRL), pBacPAK8), plant-derived expression vectors (e.g., pMH1, pMH2), animal virus-derived expression vectors (e.g., pHSV, pMV, pAdexLcw), retrovirus-derived expression vectors (e.g., pZIPneo), yeast-derived expression vectors (e.g., Pichia Expression Kit (Invitrogen)), pNVII, SP-Q01, and Bacillus-derived expression vectors (e.g., pPL608, pKTH50).

[0546] Expression vectors for expression in animal cells such as CHO cells, COS cells, NIH3T3 cells include vectors that have a promoter such as SV40 promoter (Mulligan et al., Nature (1979) 277, 108), MMTV-LTR promoter, EFl alpha promoter (Mizushima et al., Nucleic Acids Res. (1990) 18, 5322), CMV promoter, or such; and a marker gene such as a drug-resistance gene against neomycin, G418, etc. These vectors include, for example, pMAM, pDR2, pBK-RSV, pBK-CMV, pOPRSV, pOP13, etc. As a signal sequence, any one of those described in the Examples can be used.

[0547] Furthermore, the present invention provides host cells that produce an antibody of the present invention or antigen-binding fragment thereof. The host cells include cells that have a polynucleotide of the present invention or a vector of the present invention. The host cells of the present invention may be used to produce the antibodies or antigen-binding fragments of the present invention.

[0548] The host cells of the present invention are not limited to hybridomas that produce an antibody of the present invention, and may be prokaryotes or eukaryotes into which a vector of the present invention has been introduced. When eukaryotes are used as host cells, for example, animal cells, plant cells, or fungal cells can be used. Animal cells include mammal cells (CHO (J. Exp. Med. (1995) 108, 945), COS, 3T3, myeloma, BHK (baby hamster kidney), HeLa, Vero cells, etc.), amphibian cells (Xenopus oocytes (VaUe, et al., Nature (1981) 291, 358-340), etc.), insect cells (Sf9, Sf21, Tn5, etc.). As plant cells, for example, cells derived from Nicotiana tabacum are known as a protein expression system, and they may be cultured into callus and used. Fungal cells include, for example, yeast (e.g., the genus Saccharomyces (Saccharomyces cerevisiae,
Saccharomyces pombe, etc.), filamentous fungi (e.g., the genus Aspergillus (Aspergillus niger, etc.). Prokaryotic cells include, for example, E. coli and Bacillus. Vectors can be introduced into host cell by calcium phosphate methods, DEAE dextran methods, methods using cationic liposome DOTAP (Boehringer Manheim), electroporation methods, lipofection methods, etc.

Furthermore, the present invention provides antibodies produced from the above host cells.

Furthermore, the present invention provides compositions comprising the above-mentioned antibody of the present invention and a pharmaceutically acceptable carrier.

As described below, the present invention strongly suggests that each of the following antibodies are promising candidates for therapeutic antibodies for preventing Alzheimer- like phenotypes:

These animals preferably exhibit at least one symptom selected from, for example, cognitive impairment, senile plaque formation, synaptic dysfunction, A beta accumulation in brain tissues or blood, etc.

Antibodies or antigen-binding fragments contained in the pharmaceutical compositions of the present invention are not particularly limited as long as they are included in the above-mentioned antibodies or antigen-binding fragments of the present invention, and examples include the antibodies or antigen-binding fragments described herein.

When using the above-mentioned antibodies or antigen-binding fragments of the present invention for pharmaceutical compositions, they may be formulated by methods known to those skilled in the art. For example, as necessary, they can be prepared in the form of injectable sterile solutions or suspensions using water or another pharmaceutically acceptable liquid, and can be administered parenterally. For example, the antibodies or antigen-binding fragments to be included in the pharmaceutical compositions can be combined with pharmaceutically acceptable carriers or media, specifically, sterile water, physiological saline, vegetable oils, emulsifiers, sus-
pensions, surfactants, stabilizers, flavoring agents, excipients, solvents, preservatives, binders, or such, and mixed into a unit dose form required for generally accepted pharmaceutical practice. The phrase "pharmaceutically acceptable" indicates that the substance is inactive, and contains conventional substances used as diluents or vehicles for pharmaceuticals. Suitable excipients and their formulations are described, for example, in Remington's Pharmaceutical Sciences, 16th ed. (1980) Mack Publishing Co., ed. Oslo et al.

[0564] Physiological saline and other isotonic solutions containing glucose or adjuvants (for example, D-sorbitol, D-mannose, D-mannitol, and sodium chloride) can be used as aqueous solutions for injection. They can be used together with appropriate solubilizers such as alcohols, more specifically, ethanol and polyalcohols (propylene glycol, polyethylene glycol, and such), and non-ionic surfactants (Polysorbate 80™, HCO-50, and such).

[0565] Sesame oil or soybean oil can be used as an oleaginous liquid, and benzyl benzoate or benzyl alcohol can be used in combination as a solubilizer. Buffers (for example, phosphate buffer and sodium acetate buffer), soothing agents (for example, procaine hydrochloride), stabilizers (for example, benzyl alcohol and phenol), and antioxidants can be used for the formulations. Prepared injection solutions can be filled into appropriate ampules.

[0566] The administration is preferably parenteral administration, and specific examples include administration by injection, transnasal administration, transpulmonary administration, and transdermal administration. Examples of administration by injection include systemic and local administration by intravenous injection, intramuscular injection, intraperitoneal injection, subcutaneous injection, and such.

[0567] The pharmaceutical compositions contain a pharmaceutically effective amount or therapeutically effective amount of the active component (the above-mentioned antibody of the present invention). "Pharmaceutically effective amount" or "therapeutically effective amount" refers to an amount sufficient for treating and/or preventing disorders in which antigens for the above-mentioned antibodies of the present invention play an important role. For example, "a pharmaceutically effective amount" or "therapeutically effective amount" may be an amount required for reducing A beta accumulation, neutralizing A beta-induced toxicity, reducing A beta fibril formation, or such, thereby treating or preventing conditions caused by Alzheimer's disease, when the above-described antibody or antigen-binding fragment of the present invention is administered to individuals (patients). The reduction or neutralization may be, for example, a reduction or neutralization of at least approximately 5%, 10%, 20%, 30%, 40%, 50%, 75%, 80%, 90%, 95%, 99%, or 100%.

[0568] Assessment for determining such a pharmaceutically effective amount of the above-
mentioned antibodies or antigen-binding fragments of the present invention may be
carried out using a standard clinical protocol including histopathological diagnosis.

[0569] A suitable administration method may be selected depending on the age and
symptoms of the patient. The dosage of an antibody-containing pharmaceutical com-
position may be selected, for example, within the range of 0.0001 mg to 1000 mg per
kilogram body weight for each administration. Alternatively, for example, the dosage
for each patient may be selected within the range of 0.001 to 100,000 mg/body;
however, the dosage is not necessarily limited to these ranges. Although the dosage
and administration methods vary depending on the patient's body weight, age,
symptoms, and such, one skilled in the art can appropriately select them. The dosage
may be selected based on the high-dose intravenous immunoglobulin therapy (400 mg/
kg) covered by health insurance for humans.

[0570] In the present invention, the pharmaceutical compositions or agents comprising an
antibody or antigen-binding fragment of the present invention may be included in
products and kits containing materials useful for treating pathological conditions of a
subject. The products may comprise any labeled container for a compound. Suitable
containers include bottles, vials, and test tubes. The containers may be formed from a
variety of materials such as glass and plastic. The label on the container surface should
indicate that the composition is used to treat or prevent one or more conditions of the
disease. The label may also indicate descriptions for administration, and such.

[0571] In addition to the above-mentioned container, a kit containing a pharmaceutical com-
position or agent comprising an antibody or antigen-binding fragment may optionally
include a second container that stores a pharmaceutically acceptable diluent. The kit
may further include other materials desirable from a commercial and user's standpoint,
including other buffers, diluents, filters, needles, syringes, and package inserts with de-
scriptions for use.

[0572] If necessary, the pharmaceutical compositions may be provided in a pack or
dispenser device that may contain one or more unit dosage forms comprising an active
ingredient. The pack may comprise metal or plastic foil, and, for example, it is a blister
pack. The pack or dispenser device may be accompanied by instructions for admin-
istration.

[0573] In the above-mentioned pharmaceutical agents and kits, besides the antibody or
antigen-binding fragment of the present invention that is an active ingredient, sterile
water, physiological saline, vegetable oils, surfactants, lipids, solubilizing agents,
buffers, protein stabilizers (BSA, gelatin, etc.), preservatives, blocking solutions,
reaction solutions, reaction quenching solutions, reagents for treating samples, and
such, may be mixed as necessary.

[0574] Furthermore, the present invention provides methods for detecting A beta oligomers
(examples include A beta40 (A beta 1-40), A beta42 (A beta 1-42) oligomers, and A beta40/A beta42 oligomers) in samples (specimens). Examples of "samples" of the present invention include samples collected from subjects, cell culture supernatants, cell extracts, samples collected from subject animals, or such; however, they are not particularly limited as long as they contain A beta oligomers. Specifically, the present methods include the step of detecting A beta oligomers contained in a sample (e.g., a sample collected from a subject) using an antibody or antigen-binding fragment of the present invention. A beta oligomers in a sample can be detected by common immunological detection methods, for example, using ELISA (sandwich solid-phase enzyme immunoassay methods that use chemiluminescence (chemiluminescence ELISA), etc.), RIA, immunoprecipitation methods that use the obtained antibodies, immunoblotting, flow cytometry, mass spectrometry, and immunohistochemical analysis.

When A beta oligomers are detected in a sample collected from a subject by the above-mentioned measurement methods, the subject is a possible Alzheimer's disease patient (WO2009/051220, WO2009/099176, US 12/533,294, and US 12/533,348). Thus, the present invention also provides methods of diagnosing whether a subject is a possible Alzheimer's disease patient. For example, when the amount of A beta oligomers in a sample collected from a subject is compared with that from a healthy individual, and if the amount of A beta oligomers is greater in the subject than in the healthy individual, the subject is determined to be a possible Alzheimer's disease patient. Whether or not a subject is a possible Alzheimer's disease patient is diagnosed usually by physicians (including individuals under instructions from physicians; same herein below). Data on the amount of A beta oligomers in samples collected from a subject and a healthy individual, which are obtained by the present methods of diagnosis, will be useful for diagnosis by physicians. Therefore, the present methods of diagnosis can be expressed as methods of collecting and presenting data useful for diagnosis by physicians. Furthermore, "a method of diagnosing whether or not a subject is a possible Alzheimer's disease patient" is alternatively expressed as "a method of diagnosing whether or not a subject suffers from Alzheimer's disease, or is at a risk of developing Alzheimer's disease".

Specifically, the present invention provides methods for diagnosing whether or not a subject is a possible Alzheimer's disease patient, wherein the methods comprise detecting A beta oligomers in a sample collected from the subject using an antibody or antigen-binding fragment of the present invention.

More specifically, the present invention provides a method of diagnosing whether or not a subject is a possible Alzheimer's disease patient, which comprises the steps of:

(a) contacting a sample collected from a subject with the antibody or antigen-binding fragment of the present invention; and
(b) measuring the amount of A beta oligomer in the sample, wherein the subject is determined to be a possible Alzheimer's disease patient, when the amount measured in step (b) is higher than that of a healthy individual. Step (b) above can be alternatively expressed as "the step of detecting an A beta oligomer in the sample via the antibody or antigen-binding fragment of the present invention that has bound to an A beta oligomer in the sample".

[0578] Furthermore, the present invention provides methods of diagnosing whether or not a subject is a possible Alzheimer's disease patient, which comprise the steps of:

(a) contacting a sample collected from a subject with an antibody or antigen-binding fragment of the present invention and an antibody or antigen-binding fragment that binds to an A beta monomer; and

(b) measuring the ratio of A beta oligomer to A beta monomer in the sample, wherein the subject is determined to be a possible Alzheimer's disease patient, if the ratio measured in step (b) is higher than that of a healthy individual.

[0579] First, in the present methods, a sample collected from a subject is contacted with an antibody or antigen-binding fragment of the present invention and an antibody or antigen-binding fragment that binds to an A beta monomer. Herein, "contact" may be carried out, for example, by adding each of the above-mentioned antibodies or antigen-binding fragments to a sample collected from a subject, which is placed in a test tube. In this case, the antibody or antigen-binding fragment is added suitably in the form of a solution, a solid obtained by freeze-drying, or such. When adding the antibody as an aqueous solution, the solution may purely contain the antibody alone, or may contain, for example, surfactants, excipients, coloring agents, flavors, preservatives, stabilizers, buffers, suspending agents, tonicity agents, binding agents, disintegrants, lubricants, fluidity promoters, or corrigents. The concentration at which the antibody is added is not particularly limited. For example, as with human immunoglobulin formulations, 500-mg, 1000-mg, and 2500-mg freeze-dried formulations and such may be suitably used. "Contact" may be performed, for example, by adding a sample to a carrier on which the above antibody or antigen-binding fragment has been immobilized.

Preferred examples of the carrier on which the above antibody or antigen-binding fragment is immobilized include, for example, microplates, beads (magnetic beads, Sepharose beads, etc).

[0580] Next, the ratio of A beta oligomer to A beta monomer (herein, this is also referred to as "O/M index") in the aforementioned sample is measured. To measure this ratio, the measurement can be carried out using a method of comparing the oligomer and monomer ELISA values obtained from the same sample.

[0581] Then, this ratio is compared with the ratio for a healthy individual. When the ratio is higher in the subject than in the healthy individual, the subject is determined to be a
The methods of diagnosis of the present invention can be performed both in vitro and in vivo, but they are preferably performed in vitro.

Preferably, the "sample collected from a subject" of the present invention is not particularly limited as long as it is a tissue derived from a subject. Examples include the brain (brain parenchyma, and such), organs, and body fluids (blood, cerebrospinal fluid, and such) of a subject. In the present invention, the sample is preferably blood (more preferably, plasma) or cerebrospinal fluid. The "sample collected from a subject" includes a sample treated with an enzyme, treated using a column, treated by centrifugation, treated by extraction, after collection.

When the sample is a brain tissue, frozen tissue samples from the brain tissue may be homogenized and subjected to ultracentrifugation or such, to separate buffer-soluble fractions and buffer-insoluble fractions and measure A beta oligomers. For example, a brain tissue is homogenized in nine volumes of Tris-buffered saline (TS) containing a protease inhibitor cocktail, and the homogenates are ultracentrifuged at 265,000 x g for 20 minutes. Then, a collected supernatant as a soluble fraction of the brain tissue can be used as a sample for immunoblotting, ELISA, RIA, immunoprecipitation, etc. A buffer-insoluble fraction may be solubilized by formic acid (e.g., 70%) extraction, and used as a sample for immunoblotting, ELISA, RIA, immunoprecipitation, etc. Formic acid extracts may be appropriately neutralized or diluted with a buffer (e.g., 1 M Tris-HCl (pH 8.0)).

When A beta oligomers present in a brain tissue are visualized and measured by immunohistochemical methods, brain tissue sections from a subject can be used as samples. To enhance the immunoreactivity, the brain tissue sections can be pre-treated with Protease K. In immunohistochemical methods, it is not essential to quantify A beta oligomers in brain tissues. For example, if A beta deposition is observed, the subject is determined to be a possible Alzheimer's disease patient.

To increase the accuracy of A beta oligomer measurements, lipoproteins may be removed from a subject-derived sample. The depletion of lipoproteins can be performed by, for example, combining ultracentrifugation, ultrafiltration, and affinity chromatography. A specific method of depleting lipoproteins from a sample is exemplified below, but not limited thereto.

The density of a sample is adjusted to 1.25 g/ml with KBr. The sample is ultracentrifuged at 100,000 rpm and 16 degrees C for eight hours. Lipoproteins floating at a density of 1.25 g/ml and lipoprotein-depleted clarified fluid are subjected to ultrafiltration using a 3 kDa cut-off membrane (Microcon 3; Arnicon, Inc), and then frozen and stored, or stored at 4 degrees C until use. Lipoproteins are also removed by affinity chromatography using PHML-LIPOS ORB (Calbiochem, La Jolla, CA). A sample and
PHML-LIPOSORB (Calbiochem, La Jolla, CA) are combined at a ratio of 1.5:1, and mixed for 60 seconds. Then, the mixture is centrifuged at 3,000 rpm for ten minutes. The resulting supernatants can be used as lipoprotein-free samples. The lipoprotein-bound samples bound to PHML-LIPOSORB are eluted using 20 mM sodium deoxycholate. The removal of specific lipoproteins can be confirmed by 1% agarose gel electrophoresis, followed by staining with FAST-RED 7B (Wako, Osaka, Japan).

Furthermore, by size fractionation of A beta oligomers in a sample using size exclusion chromatography, ultrafiltration, or such, and subsequent detection of A beta oligomers in each fraction using the antibody or antigen-binding fragment of the present invention, the amount of A beta oligomer of each size in the sample can be measured. Fractionation by size exclusion chromatography can be performed by concentrating a subject-derived sample about ten-fold using a Microcon 3 kDa molecular weight cut-off filter (Millipore Corp.), and then applying the sample to a Superose 12 size exclusion column (1 cm x 30 cm; Pharmacia Biotech., Uppsala, Sweden; flow rate of 0.5 ml/min) equilibrated with a phosphate buffer. Alternatively, fractionation by ultrafiltration can be performed by sequential ultrafiltration using Microcon 3 kDa, 10 kDa, 30 kDa, and 100 kDa cut-off membranes. The amount of A beta oligomer contained in each fraction can be measured by ELISA, RIA, immunoblotting, immunoprecipitation, etc.

The methods of measuring an A beta oligomer of the present invention are not particularly limited as long as they comprise the step of detecting an A beta oligomer in a sample using the antibodies or antigen-binding fragments of the present invention. Preferable methods include sandwich ELISA. When sandwich ELISA is performed, an antibody or antigen-binding fragment of the present invention may be immobilized or labeled. Alternatively, an antibody or antigen-binding fragment of the present invention may be used as a primary antibody, and a labeled secondary antibody can be bound to it. The other antibody used in sandwich ELISA may be an antibody or antigen-binding fragment of the present invention, or may be a commercially available anti-A beta antibody. A specific method of detecting A beta oligomers in a sample by sandwich ELISA is exemplified below, but not limited thereto.

Microplates are coated with an antibody or antigen-binding fragment of the present invention, and 100 micro l of a sample is added and incubated continuously for 24 hours at 4 degrees C. Then, horseradish peroxidase-conjugated BA27 Fab' fragment (anti-A beta 1-40 specific to A beta 40; Wako pure chemical, Osaka, Japan) or horseradish peroxidase-conjugated BC05 Fab' fragment (anti-A beta 35-43 specific to A beta 42; Wako pure chemical, Osaka, Japan) is added and incubated at 4 degrees C for 24 hours. The chemiluminescence generated using SuperSignal ELISA Pico Chemiluminescent Substrate (Pierce, Rockford, IL, USA) is quantified by a Veritas
Microplate Luminometer (Promega).

Furthermore, if a sample is immunoprecipitated using an antibody of the present invention, and then immunoblotting analysis is performed, the size of A beta oligomer contained in a sample can be identified without carrying out size fractionation by size exclusion chromatography, ultrafiltration, or such. A specific method is exemplified below, but not limited thereto.

Immunoprecipitation is conducted by incubating a sample with an antibody of the present invention and Protein G-Septarose. The immunoprecipitated A beta oligomers are separated using an NuPAGE 4-12% Bis-Tris-Glycine gel, and transferred onto a nitrocellulose membrane or Immobilon P (Millipore) using 10 mM 3-cyclohexylamino-l-propane sulfonic acid (pH 11) containing 10% methanol at 400 mA for one hour. Non-specific binding sites on the membrane were blocked with a phosphate buffer containing 5% low-fat milk, 1% BSA, and 0.05% Tween-20 at room temperature for three hours. The A beta oligomers are detected by reaction with an antibody of the present invention, or a commercially available anti-A beta antibody such as 4G8 or 6E10 (Covance Immuno-Technologies, Dedham, MA).

Furthermore, to quantify the amount of A beta oligomer in a sample, a calibration curve may be prepared using standard samples containing a known concentration of A beta oligomer. A beta oligomers used for preparation of standard samples can be prepared by diluting a synthetic A beta (HCl form) dissolved in an HCl solution with PBS or such to a suitable concentration (e.g., 0.1 mg/ml), and incubating at 37 degrees C for an hour. The incubation temperature and time for synthetic A beta can be suitably selected. In the methods of the present invention, to obtain the ratio of A beta oligomer to A beta monomer, a calibration curve may be also prepared for A beta monomers. A beta monomers used for preparation of standard A beta monomer samples can be prepared by diluting a synthetic A beta (TFA form) dissolved in TFA (trifluoroacetic acid) with PBS or such to a suitable concentration (e.g., 0.1 mg/ml). For synthetic A beta, A beta 1-40, A beta 1-42, or such can be used.

Furthermore, the present invention provides agents (reagents) or kits for use in the above-mentioned methods of measuring A beta oligomers in a sample, or methods of diagnosing whether or not a subject is a possible Alzheimer's disease patient.

The agents for use in the above-mentioned methods of measuring A beta oligomers, or methods of diagnosing whether or not a subject is a possible Alzheimer's disease patient include agents comprising an antibody or antigen-binding fragment of the present invention. In a preferred embodiment, the agents include antibody solutions and immobilized antibodies; however, they are not limited thereto. When the agents are in a form of antibody solution, an antibody or antigen-binding fragment of the present invention is being dissolved in a suitable solvent. Those skilled in the art can
select suitable solvents for dissolving the antibody or antigen-binding fragment of the present invention such as water, physiological saline, phosphate buffer, Tris buffer, etc. The above antibody solution of the present invention may comprise, in addition to an antibody of the present invention, a buffer, protein stabilizing agent, preservative agent, blocking agent, surfactant, solubilizing agent, or such, as necessary.

When the agent of the present invention is an immobilized antibody, the antibody or antigen-binding fragment of the present invention is being carried by a suitable carrier. Examples of the carrier include microplates, beads (magnetic beads, Sepharose beads, etc.), nitrocellulose membranes, and such; however, they are not limited thereto. Those skilled in the art can select suitable carriers for immobilizing the antibodies of the present invention. Antibodies or antigen-binding fragments of the present invention can be bound to carriers using known methods.

Antibodies or antigen-binding fragments of the present invention comprised in the agents may be suitably labeled with an enzyme label, radioactive label, fluorescent label, dye label, chemical luminescence label, etc.

The kits for use in the above-mentioned methods of measuring A beta oligomers, or methods of diagnosing whether or not a subject is a possible Alzheimer's disease patient include kits comprising agents comprising an antibody or antigen-binding fragment of the present invention. Preferable examples of agents comprising an antibody or antigen-binding fragment of the present invention are as mentioned above. The kits may comprise an antibody or antigen-binding fragment of the present invention in a form of lyophilized powder. In this case, kit users dissolve the lyophilized powder of antibody or antigen-binding fragment with a suitable solvent. The kits may comprise such a solvent for dissolving the antibody or antigen-binding fragment. The kits further comprise a dilution solution for diluting the above-mentioned antibody solutions.

The kits may comprise, in addition to an agent comprising an antibody or antigen-binding fragment of the present invention, a reagent such as blocking agent, chromogenic reagent, chromogenic substrate, reaction termination solution, washing solution, buffer, primary antibody, secondary antibody, or such, as necessary. Those skilled in the art can select a suitable reagent depending on the A beta oligomer measurement method. For example, a sandwich ELISA kit comprising a microplate on which the antibody is immobilized may further comprise a labeled anti-A beta antibody, chromogenic substrate, reaction termination solution, washing solution, plate seal, etc. Furthermore, in a sandwich ELISA kit comprising an antibody solution of the present invention may further comprise a microplate on which an anti-A beta antibody is immobilized, chromogenic substrate, reaction termination solution, washing solution, plate seal, labeled secondary antibody (if the antibody of the present
invention is not labeled), etc.

The kits may further comprise a standard sample for preparing a calibration curve of A beta oligomer. The standard sample may be a solution containing a known concentration of A beta oligomer. The kits may comprise a diluting solution for stepwise dilution of the standard solution. Alternatively, lyophilized powder of A beta oligomers may be included, and a solvent for dissolving the lyophilized powder may be comprised. Furthermore, the kits may comprise a solution or lyophilized powder of an A beta monomer, and kit uses may prepare an A beta oligomer standard solution by incubating the A beta monomer solution to polymerize A beta monomers.

When the kits are for use in methods of diagnosing whether or not a subject is a possible Alzheimer's disease patient, they may comprise a sample (a brain tissue, cerebrospinal fluid, blood, plasma, etc.) collected from a healthy individual as a negative control, and a sample collected from a AD brain patient as a positive control.

The kit may further include other materials desirable from a commercial and user's standpoint, including buffers, diluents, filters, needles, syringes, and attached documents including descriptions for use (instructions, CD-ROM, etc.). The agents and such contained in the kit may be included in a container with a label. Such a container includes a bottle, vial, test tube, microtube, etc.

Examples

Hereinbelow, the present invention is specifically described with reference to the Examples, but it is not to be construed as being limited thereto.

Methods

Preparation of antigens

A fluorescent dye, 6-carboxytetramethylrhodamine (6-TAMRA) (SIGMA) was chemically linked to the N terminus of a synthetic A beta 1-40 peptide (Peptide Institute, Inc.) to produce a modified A beta. An oligomer-rich sample (A beta 1-40 oligomer) was prepared by copolymerizing the modified A beta and synthetic A beta 1-40 peptide. It is preferable to adjust the conditions so that the fluorescence intensity determined by ThT assay (Yamamoto N, et al: J Biol Chem, 282: 2646-2655, 2007), which is described below, is one-fourth or less the fluorescence intensity in the absence of a modified A beta. More specifically, it is preferred that 100 micro M each of the modified A beta and synthetic A beta 1-40 peptide are mixed, and polymerized for 20 hours.

Preparation of antibody-producing hybridomas

BALB/c mice were immunized by injecting the antigen prepared by the method
described above into their foot pads or abdominal cavities. Then, booster immunization
was carried out six times. Hybridomas were prepared from inguinal lymph node cells
or spleen cells by fusion with Sp2/O-Agl4 cells using Polyethylene Glycol 1500.

[0607] **ELISA screening (primary screening)**

Hybridoma culture supernatants were added to ELISA plates immobilized with A
beta oligomers and reacted. Color development was carried out using an HRP-
conjugated anti-mouse IgG antibody and TMB solution. A beta oligomers used in this
method is A betal-40 (HCl form) after one hour incubation or above-described extracted antigens of A beta 1-42 tetramer.

[0608] **Dot blot analysis (secondary screening)**

Dot blot analysis was carried out for hybridomas that gave positive result for primary
screening. In this analysis, 0.1 micro g/dot of three types of A beta; synthesized A beta
1-40 (TFA form) as A beta monomer, synthesized A betal-40 (HCl form) after 1 hour
incubation as A beta oligomer, and synthesized A betal-42, were immobilized onto ni-
trocellulose membrane and used. The membrane was blocked with Tris Buffer
containing 5% low-fat milk and 0.05% Tween-20, and reacted with hybridoma culture
supernatants and detected using an HRP-conjugated anti-mouse IgG antibody and a
chemiluminescence kit (ECL).

[0609] **Antibody isotyping**

Isotyping of purified immunoglobulins were carried out using a Serotec (Oxford,
UK) Mouse Monoclonal Antibody Isotyping Test Kit.

[0610] **Identification of antibody sequences**

RNAs were purified from hybridomas (1 x 10^6 cells) produced by the method
described above using FastPure RNA Kit (TaKaRa, Japan). Using the RNAs as
templates, cDNAs were synthesized using 5’ RACE System (Invitrogen, USA) and

cDNA syntheses and PCR were carried out according to the manual attached to the product, and primers attached to the product (AAP: GGCCACGCGTCGACTAG-TACGGGGGGGGGGGG (SEQ ID NO: 2973), AUAP: GGCCACGCGTC-GACTAGTAC (SEQ ID NO: 2974)) were used as 5' side primers. Taq DNA polymerase High Fidelity (Invitrogen, USA) was used for PCR.

Formed colonies were cultured overnight in a liquid selection medium and plasmids were purified using High Purity Plasmid Miniprep System (MARIGEN BIOSCIENCES, USA). Control antibodies

Anti-A beta antibody 6E10 was used as a control antibody to compare to the antibodies of the present invention. Anti-A beta antibody 6E10 (Covance Immuno-Technologies, Dedham, MA) is a mouse monoclonal antibody that recognizes a sequence in A betal-16 as an epitope, and has no selectivity against A beta oligomer (binds to A beta monomer).

Competitive ELISA

A beta oligomer antigens were prepared by diluting synthetic A betal-40 (HCl form) at 0.1 mg/ml with PBS and incubating at 37 degrees C for one hour. A beta monomer was prepared by diluting synthetic A betal-40 (TFA form) at 0.1 mg/ml with PBS. First, 400 ng/well of A beta oligomer was immobilized onto 96-well immunoplate and the plate was blocked with BSA. Next, antibodies of the present invention or a control anti-A beta antibody (6E10) were each mixed with serially-diluted A beta monomer or A beta oligomer at a range of 100 pg/ml to 100 micro g/ml and incubated for two hours, then each mixture was added to 96-well immunoplate and incubated at room temperature for ten minutes. Binding abilities of each antibodies to immobilized A beta oligomer were detected by reacting with HRP-conjugated anti-mouse IgG antibody and visualized by measuring absorbance at 450 nm using TMB solution. In the present method, two types of A betal-40 (A betal-40 monomer and A betal-40 oligomer),
which have the same sequence but have different structure and polymerization characters due to their structure, was compared as competitive substance. Accordingly, the method can compare the binding difference of the antibodies only derived from the existence of A beta 40 polymerization, and thus can obtain extremely reliable results.

**Analysis of affinity to A beta oligomer**

The analysis was carried out by Surface Plasmon Resonance (SPR) using Biacore 3000 (GE Healthcare Sciences). A beta oligomer was immobilized onto a sensor chip (CM5) as a ligand and antibodies of the present invention and control 6E10 antibody were used as analyte, kinetics analysis was carried out. Analysis was conducted at analyte antibodies at the following five concentrations: 1.25, 2.50, 5.00, 10.00, and 20.00 micro g/ml, and association rate constant (ka), dissociation rate constant (kd), and dissociation constant (KD) was calculated using BiaEvaluation software. A beta oligomer used in the analysis was prepared by diluting synthetic A beta 40 (HCl form) at 0.1 mg/ml with PBS and incubating at 37 degrees C for one hour.

**A beta-induced neurotoxicity assay**

Human neuroblastoma cell (SH-SY5Y cell) was plated into 24-well plates at a density of 150,000 cells/well, and cultured for 24 hours in DMEM containing 10% FBS. Then, the medium was replaced a serum-free medium containing 12.5 micro M a beta 1-42 in the presence or absence of antibodies and cells were cultured for another 24 hours. To determine the cytotoxicity induced by A beta 42, LDH contents released into the medium from dead cells was determined using CytoTox96 Kit (manufactured by Promega).

**Activity of suppressing A beta amyloid fibril formation**

A beta 42 solution diluted to 12.5 micro M with cell culture medium was incubated in the presence or absence of antibodies of the present invention at 37 degrees C for 24 hours. Then, the solutions were mixed with Thioflavin T (ThT) solution (5 micro M ThT, 50 mM Glycine-NaOH, pH 8.5), ThT fluorescence intensity, which is correlated with A beta amyloid fibril contents, were determined using fluorescence spectrophotometer (RF-5300PC; Shimadzu Co., Kyoto, Japan). Excitation and emission wavelengths were set at 446 nm and 490 nm, respectively. Fluorescence intensity was measured immediately after the mixture was prepared.

**Immunoblotting**

Brain homogenates of Tg2576 or wild type mice were used for APP binding assay. The homogenates were electrophoresed in NuPAGE Tris-Glycine 4-12% gel and transferred to a PVDF membrane. The membrane was reacted to each antibodies after blocking by PVDF blocking reagent (TOYOBO). The bindig ability was detected by an HRP-conjugated anti-mouse IgG antibody and a chemiluminescent regent (Immobilon western, Millipore).
Selection of anti-A beta oligomer antibodies

46 mice were immunized with A beta 1-40 oligomer antigen and inguinal lymph node or spleen were isolated from each mouse. Cells derived from each organs were fused with myeloma (Sp2/O-Agl4) and dispensed into seven plates of 96-well plate per mice and cultured. Hybridomas producing the antibodies of interest were selected by adding culture supernatant from the 96-well plate onto ELISA plates immobilized with A beta oligomer, and reacting them to analyze. As a result, 507 positive cells were selected from 30,912 wells ((46 mice) x (7 plates) x (96 wells)).

The above-described ELISA screening also select antibodies that do not specifically bind to A beta oligomer (antibodies that bind to ELISA plate other than A beta oligomer). By performing dot blot analysis, these non-specific antibodies can be excluded. Accordingly, dot blot analysis using ELISA-positive cells were carried out. For dot blot analysis, two types of oligomers and A beta monomer were spotted and excluded non-specific antibodies (antibodies that do not bind to the spotted A beta oligomer were excluded), as well as specificity against A beta oligomer (absence of binding to A beta monomer) was confirmed. As a result, 145 positive antibodies among 507 ELISA-positive cells were selected (Fig. 1).

Identification of antibody sequences

The variable region sequences were analyzed by the above-mentioned method, for 145 antibodies selected by the above dot blot analysis. As a result, the following nucleotide sequences of regions comprising VH CDR1, CDR2, and CDR3 were obtained:

CDR sequences were determined from the amino acid sequences, based on the definition by Kabat (Kabat, Elvin A., Sequences of proteins of immunological interest 5th ed., National Institutes of Health, 1991). The CDR sequences of the antibodies are shown in Table 1. In Table 1, "Name" shows the name of each antibody, "class" shows the IgG subclass of each antibody, "chain" shows whether the chain is an H or L chain, and "(na)" means "nucleic acid".

Some of the obtained VH and VL sequences contained signal peptides or lacked N-terminal or C-terminal sequences. If sequences are lacking, they are supplemented. Thus, the VH and VL sequences without signal sequences were determined based on the homology with previously-reported antibody sequences.

[0635] Competitive ELISA analysis

Dot blot analysis is a method for analyzing a reactivity against A beta monomer or
oligomer immobilized onto nitrocellulose membrane. However, A betas are solubilized
into fluids such as interstitial fluid, cerebral fluid, or blood. Then, the present analysis
was carried out for investigating specific binding to A beta oligomers in solutions and
difference of selectivity to A beta monomer. Competitive ELISA is a method for de-
termining oligomer specificity by preliminarily reacting with antibodies to be
measured and serially-diluted A beta monomer or oligomer in solutions, and carrying
out ELISA by adding the solutions to a plate immobilized with A beta oligomer. When
an antibody is an A beta oligomer-specific antibody, ELISA reaction decreases in an A
beta oligomer concentration-dependent manner in a solution reacted with A beta
oligomer, but does not decrease in a solution reacted with A beta monomer or
decreases when A beta concentration becomes higher than the oligomer concentration.
130 antibodies were analyzed and the result shown in Fig. 2 was obtained. The 129 an-
tibodies except for IR-088 showed high binding specificity even in the solution.
Meanwhile, antibody that react with both A beta monomer and oligomer (6E10) used
as a control showed equivalent ELISA reactivity against monomer and oligomer. Fur-
thermore, the competitive ELISA results in which the inhibitor concentration is shown
as molar concentration are shown in Fig. 3. IC_{50} and A beta oligomer selectivity over A
beta monomer (A beta monomer IC_{50}/A beta oligomer IC_{50}) calculated by the com-
petitive ELISA in Fig. 3 are shown in Table 2.

[0636]
To investigate the binding ability of the antibodies of the present invention to A beta oligomer, an analysis of affinity for A beta oligomer was performed.

Assay of the neutralization ability of the anti-A beta oligomer antibodies against A beta-induced cytotoxicity

A beta oligomers cause cytotoxicity to neuronal cells. To assess whether the anti-A beta oligomer antibodies of the present invention neutralize A beta-induced cyto-
toxicity, in vitro assay using human neuroblastoma cells (SH-SY5Y cells) was performed. Most of the antibodies showed the neutralization ability against A beta-induced cytotoxicity. Examples of the antibodies showing the neutralization ability are shown in Fig. 5. In the graphs, the value of Y axis indicates the relative rate to the cytotoxicity of A beta only (no antibody).

**Assay of the inhibition ability of the anti-A beta oligomer antibodies against A beta-fibril formation**

A beta monomers form fibrils as a result of multimerization when they are incubated in a neutral pH buffer. To assess whether the antibodies of the present invention inhibit the fibril formation, an antibody and A beta were mixed and incubated for 24 hours and the mixture were measured by fluorescence of ThioflavinT which reflects the amount of fibrils. Most of the antibodies showed the inhibition ability against A beta fibril formation. Examples of the antibodies showing the inhibition ability are shown in Fig. 6. In the graph, the value of Y axis indicates the relative rate to the fibril formation of A beta only (no antibody).

**Immunoblotting to confirm that the anti-A beta oligomer antibodies do not bind to APPfamyloid precursor protein**

It is important for escape of side effect that anti-A beta antibodies do not bind to APP which is the physiological protein expressed in a healthy body. Anti-A beta oligomer antibodies are expected not to bind to APP because they recognize the conformational domain of A beta oligomer that is not present in APP. Therefore, immunoblotting was performed to assess whether the anti-A beta oligomer antibodies of the present invention do not bind to APP. It was confirmed that they do not bind to human APP (compared with the result of control 6E10 antibody). Examples of immunoblotting analysis are shown in Fig. 7. This data also shows that the antibodies of the present invention have low binding affinity to proteins other than A beta oligomer, and the specificity of the antibodies is high (compared with the result of control 6E10 antibody).

**Industrial Applicability**

The antibodies provided by the present invention are expected to contribute to the establishment of preventive/therapeutic methods selective to molecules responsible for evoking pathological conditions of Alzheimer's disease, and the establishment of early diagnostic markers for Alzheimer's disease.

Form PCT/ISA/210 (continuation of first sheet (2)) (July 2009)
Antibodies claimed in claims Nos.1-3 involve a common technical feature, i.e., [they recognize an isolated A beta oligomer as an antigen, wherein they does not bind to an A beta monomer] respectively. However, the said technical feature doesn't make any contribution over the prior art in light of the content disclosed by D1-D3, and therefore doesn't constitute a special technical feature. In addition, the said antibodies share no common critical structural factor.

Thus, there are 145 inventions in the claims of this application as shown below.
