(54) **Title: EYE EXAMINATION APPARATUS FOR USE WITH A SMARTPHONE**

FIG. 1f

(57) **Abrégé/Abstract:**

Disclosed is an eye examination apparatus for use with a smartphone. The eye examination apparatus has a body having a first eye opening and a second eye opening for a user to see into the eye examination apparatus using two eyes. In accordance with an embodiment of the disclosure, the eye examination apparatus has a coupling for receiving a smartphone having a display and a camera and for holding the smartphone in a predefined position in relation to the body, such that the camera of the smartphone is positioned to acquire ophthalmic images through the first eye opening, and the display of the smartphone is viewable through the second eye opening. In this manner, it is possible for the user to have an eye examination performed remotely outside of a clinician's office without specialized equipment by instead using their own smartphone.

Date Submitted: 2023/10/24

CA App. No.: 3216580

Abstract:

Disclosed is an eye examination apparatus for use with a smartphone. The eye examination apparatus has a body having a first eye opening and a second eye opening for a user to see into the eye examination apparatus using two eyes. In accordance with an embodiment of the disclosure, the eye examination apparatus has a coupling for receiving a smartphone having a display and a camera and for holding the smartphone in a predefined position in relation to the body, such that the camera of the smartphone is positioned to acquire ophthalmic images through the first eye opening, and the display of the smartphone is viewable through the second eye opening. In this manner, it is possible for the user to have an eye examination performed remotely outside of a clinician's office without specialized equipment by instead using their own smartphone.

EYE EXAMINATION APPARATUS FOR USE WITH A SMARTPHONE

Related Application

[1] This patent application claims priority to United States provisional patent application no. 63/186,983 filed May 11, 2021, and United States provisional patent application no. 63/209,227
5 filed June 10, 2021. Both of these United States provisional patent applications are incorporated by reference herein in their entirety.

Field of the Disclosure

[2] This disclosure relates to eye examination apparatuses for vision assessment and diagnostic purposes.

10 Background

[3] Every year, thousands of people suffer from brain and eye diseases, such as concussion for example. When a person becomes injured, it is prudent to assess whether the person is suffering from concussion or showing any other vision impairment symptoms. Portable vision diagnostic devices can help assess whether individuals are injured and/or concussed, with
15 a view to treating those that are injured and/or concussed while enabling others to return to their normal activities.

[4] In underprivileged areas and countries, where access to a specialist is either difficult or impossible, portable eye exam devices are useful to provide eye-care and vision assessment options to identify life or vision-threatening diseases that should receive immediate medical
20 attention from benign eye conditions that are not medical emergencies. Additionally, such convenient eye and vision assessments could help seniors and physically challenged individuals who face difficulty travelling to a physician's clinic. Eye and vision assessment devices can facilitate convenient eye examinations from anywhere in the world. They provide a plethora of benefits such as allowing users to get eye assessments from a doctor of their choice; they reduce
25 dependence on typical eye examination setups; and they can potentially eliminate travelling to eye centres or clinics for conventional or complex eye-examinations.

- 2 -

[5] Unfortunately, currently available portable eye-examination devices are either too bulky or complex to use. Some conventional devices only provide tailored solutions i.e. they identify some specific eye condition but are not useful for routine eye-checkups and vice versa. Often times it is also found that conventional devices lack an expected level of accuracy. More
5 importantly, they fail to identify severe eye conditions (ophthalmic eye diseases) and therefore are not reliable.

Summary of the Disclosure

[6] Disclosed is an eye examination apparatus for use with a smartphone. The eye examination apparatus has a body having a first eye opening and a second eye opening for a user
10 to see into the eye examination apparatus using two eyes. In accordance with an embodiment, the eye examination apparatus has a coupling for receiving a smartphone having a display and a camera and for holding the smartphone in a predefined position in relation to the body, such that the camera of the smartphone is positioned to acquire ophthalmic images through the first eye opening, and the display of the smartphone is viewable through the second eye opening.

[7] In this manner, it is possible for the user to have an eye examination performed remotely outside of a clinician's office without specialized equipment by instead using their own smartphone. This is an improvement over the currently available portable eye-examination devices. The eye examination apparatus it is relatively easy to use with one or two smartphones and therefore may be suitable for use by households, schools, paramedics, etc.

[8] Also disclosed is a computer-implemented method of performing an eye examination. The method involves capturing, using a camera of a smartphone, a picture or video of a first eye of a user, and displaying, using a display of the smartphone, a picture or video for a second eye of the user. The computer-implemented method can be used in combination with the eye examination apparatus summarized above.

[9] Also disclosed is a non-transitory computer readable medium having recorded thereon statements and instructions that, when executed by at least one processor, cause the at least one processor to perform a method for eye examination as summarized above.

[10] Other aspects and features of the present disclosure will become apparent, to those ordinarily skilled in the art, upon review of the following description of the various embodiments of
30 the disclosure.

Brief Description of the Drawings

[11] Embodiments will now be described with reference to the attached drawings in which:

Figures 1a to 1d are perspective views of an eye examination apparatus that makes use of at least one smartphone;

Figure 1e is a schematic of the eye examination apparatus being worn by a user for an eye examination;

Figure 1f is a perspective view of the eye examination apparatus equipped with a smartphone;

Figure 1g is a side view of the eye examination apparatus equipped with two smartphones for an eye examination;

Figure 1h is an exemplary ray diagram for the eye examination apparatus illustrating how a camera captures ophthalmic images during an eye examination;

Figure 1i is a schematic of the eye examination apparatus equipped with two smartphones and at least one condenser lens for funduscopy;

Figure 1j is a schematic of the eye examination apparatus equipped with two smartphones and a mirror 156 for OCT (Ocular Coherence Tomography);

Figure 1k is a schematic of the eye examination apparatus equipped with a refraction apparatus for refraction eye examination;

Figures 1l and 1m are schematics of the refraction apparatus of Figure 1k;

Figure 1n is a schematic of the wheels of the refraction apparatus of Figures 1l and 1m;

Figure 1o is a schematic of the eye examination apparatus having a pair of occluders;

- 4 -

Figure 1p is a flowchart of a computer-implemented method of performing an eye examination;

Figure 2a is a schematic of an eye examination apparatus that can be used in a professional setting;

5 Figure 2b is a schematic of a sensor module of the eye examination apparatus of Figure 2a;

Figures 2c to 2f are perspective views of the eye examination apparatus implemented with a headband;

10 Figures 2g to 2l are perspective views of the eye examination apparatus implemented with a helmet; and

Figures 3a to 3c are perspective views of another eye examination apparatus that can be used in a professional setting.

Detailed Description of Embodiments

15 [12] It should be understood at the outset that although illustrative implementations of one or more embodiments of the present disclosure are provided below, the disclosed systems and/or methods may be implemented using any number of techniques, whether currently known or in existence. The disclosure should in no way be limited to the illustrative implementations, drawings, and techniques illustrated below, including the exemplary designs and implementations illustrated and described herein, but may be modified within the scope of the appended claims
20 along with their full scope of equivalents.

Smartphone Embodiment

25 [13] Referring first to Figures 1a to 1d, shown are perspective views of an eye examination apparatus 100 that makes use of at least one smartphone. The eye examination apparatus 100 has a closed state (Figure 1a) in which a front cartridge 111 and an upper cartridge 110 are disposed within the eye examination apparatus 100. The eye examination apparatus 100 also has an open state (Figure 1c) in which the front cartridge 111 and/or the upper cartridge 110 are slid out or removed from the eye examination apparatus 100. The front cartridge 111 and the upper cartridge 110 are each configured to hold a smartphone and are

- 5 -

slidably insertable into a body of the eye examination apparatus 100. The eye examination apparatus 100 has two eye openings 101 and 102.

[14] Referring now to Figure 1e, shown is a schematic of the eye examination apparatus 100 being worn by a user for an eye examination. In some implementations, as shown
5 in the illustrated example, the eye examination apparatus 100 has a headband 112 and 113 for securing the eye examination apparatus 100 to the user. The headband 112 and 113 can for example include an upper strap 112 and a lower strap 113 both configured to be worn on the head by the user to retain the eye examination apparatus 100 in place during the eye examination. Other securing means are possible.

[15] In the illustrated example, the front cartridge 111 and the upper cartridge 110 each hold a smartphone (i.e. two smartphones in total) for the eye examination. As explained in further detail below, having two smartphones can enable the eye examination of both eyes simultaneously. However, it is noted that an eye examination is possible with a single smartphone, for example the smartphone in the front cartridge 111, or alternatively the smartphone in the upper cartridge 110.

[16] Referring now to Figure 1f, shown is a perspective view of the eye examination apparatus 100 equipped with one smartphone 161. The smartphone 161 is placed in the front cartridge 111 and inserted into a front cartridge slot. Once inserted, the front cartridge 111 holds the smartphone 161 in a predefined position in relation to the body, such that a camera 115 of the smartphone 161 is positioned to acquire ophthalmic images through the first eye opening 101, and
20 a display 116 of the smartphone 161 is viewable through the second eye opening 102. This can enable an eye examination of one eye at a time.

[17] Referring now to Figure 1g, shown is a side view of the eye examination apparatus 100 equipped with two smartphones 161-162 for an eye examination. As noted above, two smartphones 161-162 can be utilized to enable an eye examination of both eyes
25 simultaneously. To support this, the eye examination apparatus 100 has a semi-transparent mirror 106 coupled to the body. With respect to the user's right eye 171, the semi-transparent mirror 106 is used to reflect light for a camera 117 of the smartphone 162 in the upper cartridge 110 while enabling light to pass through for the display of the smartphone 161 in the front cartridge 111. Conversely, with respect to the user's left eye (not shown), the semi-transparent mirror 106 is used
30 to reflect light for a display of the smartphone in the upper cartridge 110 while enabling light to pass through for the camera of the smartphone 162 in the upper cartridge 110.

- 6 -

[18] Each smartphone 161-162 functions as a DCS (Display Camera Set). In some implementations, the DCS 161 in the front cartridge 111 is designed as a primary DCS while the DCS 162 in the upper cartridge 110 is designed as a secondary DCS, although the opposite designation is possible. The camera 117 of the secondary DCS 162 and the display 116 of the primary DCS 161 are used for the user's right eye 171, while the camera 115 of the primary DCS 161 and the display (not shown) of the secondary DCS 162 are used for the user's left eye (not shown). Therefore, images of the right eye 171 are captured by the camera 117 of the secondary DCS 162 through a 90-degree reflection off of the semi-transparent mirror 106, while images of the left eye (not shown) are captured directly by the camera 115 of the primary DCS 161. Meanwhile, the right eye 171 can see the display 116 of the primary DCS 161 through the semi-transparent mirror 106, and the left eye (not shown) can see the display (not shown) of the secondary DCS 162 through a 90-degree reflection off of the semi-transparent mirror 106. In some implementations, the two DCSs 161-162 have software that when executed enable the two DCSs 161-162 to operate in sync and present similar images to the two eyes. In other implementations, the two DCSs 161-162 can operate independently and show different images. The two DCSs 161-162 can also present two images that are designed dichoptically and stereoscopically to present objects or scenes in depth. Other implementations are possible.

[19] In the illustrated example, the upper cartridge 110 is configured to position the secondary DCS 162 in a top portion of the body of the eye examination apparatus 100. In other implementations, a lower cartridge (not shown) is configured to position the secondary DCS 162 in a bottom portion of the body. More generally, the eye examination apparatus 100 can have a second coupling for receiving the secondary DCS 162 and for holding the same in a predefined position in relation to the body, whether this predefined position is in the top portion of the body or in the bottom portion of the body. Operation of the eye examination apparatus 100 is not dependant on whether the secondary DCS 162 is in the top portion of the body or in the bottom portion of the body, because reflection off of the semi-transparent mirror 106 is possible from the top portion of the body and the bottom portion of the body.

[20] As used herein, "ophthalmic images" can include eye surface images, eyelid images, optic nerve images, retina images, and/or other images relating to ophthalmology. Generally speaking, to acquire ophthalmic images using a camera, the camera would be positioned in front of a patient's eye and in line with a visual axis of the eye, or in another position provided that reflection and/or refraction of light (e.g. using a mirror and/or prism) enables the camera to

- 7 -

similarly capture the front of the patient's eye. In either case, preferably the center of the patient's retina (i.e. macula and optic nerves) can be captured.

[21] Referring now to Figure 1h, shown is an exemplary ray diagram for the eye examination apparatus 100 illustrating how a camera 115 captures ophthalmic images during an eye examination. In some implementations, the eye examination apparatus 100 has a pair of convex lenses 151, for example but not limited to 50D, for the first eye opening 101 and the second eye opening 102. In some implementations, the eye examination apparatus 100 also has a second pair of convex lens 152, for example but not limited to 20D, for the camera 115 of the first smartphone 161 and the camera 117 of the second smartphone 162 (not shown). In some implementations, the convex lenses 151 and 152 provide enough magnification to enable a wide range of possibilities for the cameras 115 and 117 of the smartphones 161-162, as smartphones may have cameras with lower resolution than desired. However, for cameras with very high resolution, such magnification can be reduced and maybe even eliminated in which case the convex lenses 151 and 152 can be omitted. Other implementations are possible, for example but not limited to emitting, capturing and analyzing rays of light for ocular coherence tomography.

[22] In some implementations, the eye examination apparatus 100 also has at least one light emitter 153 positioned to generate infrared or visible light out of the first eye opening 101 and the second eye opening 102 via reflection off of the semi-transparent mirror 106. In some implementations, the at least one light emitter 153 includes a first infrared emitter positioned to generate infrared light out of the first eye opening 101 and a second infrared emitter positioned to generate infrared light out of the second eye opening 102. In some implementations, infrared light can be used for lighting inside the eye examination apparatus 100, the reflection of which being captured by infrared cameras 115 and 117 on the primary and secondary DCSs 161-162. Using this functionality of the primary and secondary DCSs 161-162, the user can avoid pupil constriction and take pictures of the back of the eye 171 with an instant flashlight when the cameras 115 and 117 are focused and the picture of retina is clear. In some implementations, the at least one light emitter 153 is part of the secondary DCS 162, although other implementations are possible in which the at least one light emitter 153 is part of the first DCS 161 or separate from both the DCSs 161-162.

[23] In the illustrated example, the camera 115 of the primary DCS 161 is positioned directly in front of the patient's eye 171 and in line with a visual axis of the eye so that the camera 115 can capture a center of a retina (i.e. macula and optic nerves) of the eye 171. In this

- 8 -

way, the camera 115 has line of sight out of the eye opening of the eye examination apparatus 100. As used herein, "line of sight" refers to a substantially straight path without reflection within the eye examination apparatus 100, although some amount of refraction may be possible, for example through the semi-transparent mirror 106 and/or any lenses such as the convex lenses 152. Note
5 that the camera 117 of the secondary DCS 162 is not positioned directly in front of a patient's eye. Rather, the camera 117 of the secondary DCS 162 is positioned in the upper cartridge 110, although other positions are possible. Nonetheless, by using the semi-transparent mirror 106, it is possible for the camera 117 of the secondary DCS 162 to capture the center of the retina of the patient's other eye. The eye examination apparatus 100 enables proper positioning of the primary
10 DCS 161 and the secondary DCS 162 to acquire ophthalmic images.

[24] According to the eye examination apparatus 100, it is possible for the user to have an eye examination performed remotely outside of a clinician's office without specialized equipment by instead using their own smartphone(s) 161-162. This is an improvement over the currently available portable eye-examination devices. The eye examination apparatus 100 does not require
15 any high-end cameras. The eye examination apparatus 100 is relatively easy to use with one or two smartphones 161-162 and therefore may be suitable for use by households, schools, paramedics, etc.

[25] Referring now to Figure 1i, shown is a schematic of the eye examination apparatus 100 equipped with two smartphones 161-162 and at least one condenser lens 154 for
20 funduscopy. Funduscopy is a type of examination to check a fundus of an eye 172, including the retina and optic nerve, and often uses magnified or focused light to do so. In the illustrated example, the condenser lens 154 renders a divergent beam from the light emitter 153 of the smartphone 162 in the upper cartridge 110 into a parallel beam, which is reflected off of the semi-transparent mirror 106, and a second lens 151 condenses the parallel beam into a converging
25 beam onto the retina of the eye 172. In alternative implementations, the condenser lens 154 renders the divergent beam into a converging beam onto the retina in which case the second lens 151 may be omitted. In some implementations, one or both of the lenses 154 and 151 are adjustable for changing focus and focal distances to adapt to different eye sizes and anatomical variations. The camera 115 of the smartphone 161 in the front cartridge 111 serves as a detector
30 that captures light reflected from the retina of the eye 172 and passes through the semi-transparent mirror 106 to reach the camera 115. Thus, a combination of the two smartphones 161-162, the

- 9 -

semi-transparent mirror 106, and the at least one condenser lens 154 enables funduscopy to be performed.

[26] In the illustrated example, the light emitter 153 is from the smartphone 162 in the upper cartridge 110 and the camera 115 is from the smartphone 161 in the front cartridge 111.

5 Additionally, or alternatively, a light emitter from the smartphone 161 in the front cartridge 111 and the camera 117 of the smartphone 162 in the upper cartridge 110 can be utilized. Both implementations are possible simultaneously, which can make it possible to perform funduscopy for both eyes, or separately.

[27] Referring now to Figure 1j, shown is a schematic of the eye examination

10 apparatus 100 equipped with two smartphones 161-162 and a mirror 156 for OCT (Ocular Coherence Tomography). Optical coherence tomography is an imaging technique that uses interferometry to capture high-resolution images based on interference of superimposed waves from a reference arm and a sample arm. In the illustrated example, a low coherence light source 153a generates low coherence light onto the semi-transparent mirror 106, which functions
15 as a beam splitter. For the reference arm, some of the low coherence light passes through the semi-transparent mirror 106, reflects off of the mirror 156, reflects off of the semi-transparent mirror 106, and is received by the camera 115 of the smartphone 161 in the front cartridge 111. For the sample arm, the rest of the low coherence light from the low coherence light source 153a reflects off of the semi-transparent mirror 106, reflects off of the retina of the eye 172, passes
20 through the semi-transparent mirror 106, and is received by the camera 115. The camera 115 thus receives a reference light wave from the reference arm and a sample light wave from the sample arm. The reference light wave and the sample light wave can interfere constructively (i.e. strengthening in intensity) when in phase or interfere destructively (i.e. weakening in intensity) when out of phase. Such interference between the reference light wave and the sample light wave
25 provides imaging information which can be detected as an analog interference OCT signal. In some implementations, the camera 115 is capable of detecting NIR (Near Infrared Light) to help capture the analog interference OCT signal.

[28] In some implementations, the sample arm includes a lens 151 to condense the low coherence light into a converging beam onto the retina of the eye 172. Furthermore, in some
30 implementations, the sample arm includes a 2D MEMS (Microelectromechanical) mirror 155 which is an optical beam-steering device which provides a lateral scanning of the OCT. Collimated light incidents on a dual-axis galvo-mirrors of the 2D MEMS mirror 155 and is redirected to the lens 151,

- 10 -

which operates as a telecentric objective lens. The lens 151 focuses the light onto the retina of the eye 172 and back-reflected light is received by the lens 151 and focused back through the semi-transparent mirror 106. In some implementations, the lens 151 and the 2D MEMS mirror 155 are adjustable to provide variable focus and projection.

5 **[29]** In some implementations, the camera 115 samples the analog interference OCT signal at equal spectral intervals. Each scan produces depth information from the interference pattern by reaction at different depths in the form of an A-scan. An A-scan is a one-dimensional image of the sample (e.g. retina of the eye 172) at a specific depth. A cross-sectional image of the microstructure of the sample can be obtained by integrating multiple A-scans. In some
10 implementations, the analog interference OCT signal which is captured is converted into a digital signal, and OCT fringe data are then processed locally on the smartphone or sent to a host computer where signal processing can be performed.

[30] Referring now to Figure 1k, shown is a schematic of the eye examination apparatus 100 equipped with a refraction apparatus 188 for refraction eye examination. A
15 refraction eye examination is an eye exam that measures a person's prescription for eyeglasses or contact lenses. The refraction apparatus 188 is an optional accessory that can be attached to the eye examination apparatus 100 in order to enable refraction eye examination and subsequently detached. In some implementations, the refraction apparatus 188 attaches to the eye examination apparatus 100 using magnetic pins which are installed at the four corners on the back of the eye
20 examination apparatus 100 and front of the refraction apparatus 188. However, other implementations for attaching the refraction apparatus 188 to the eye examination apparatus 100 are possible.

[31] Referring now to Figures 1l and 1m, shown are schematics of the refraction apparatus 188 of Figure 1k. The refraction apparatus 188 has at least two wheels 180 and 181 on
25 each side of the refraction apparatus 188, for a total of at least four wheels. In some implementations, each wheel protrudes from the side, creating a dial 189 for the wheel that can be used to turn the wheel. In some implementations, the refraction apparatus 188 has additional wheels (not shown). More wheels may be present for further detailed variety of refraction or eye examinations or treatment delivery.

30 **[32]** Referring now to Figure 1n, shown is a schematic of the wheels 180 and 181 of the refraction apparatus 188 of Figures 1l and 1m. The first wheel 181 has spherical convex and

- 11 -

concave lenses 183 which are used to test refraction. The second wheel 180 has cylindric convex and concave lenses 182 for astigmatism examination. Color red, green, blue, etc. filters, pinholes, any prisms, occluders, neutral density filters or any other electronically modified or physically modified or controlled lenses or filters may be used in the wheels 180 and 181.

5 **[33]** In the illustrated example, a user can change the lenses or filters on the wheels 180 and 181 using the dials 189. In other implementations, the lenses or filters on the wheels 180 and 181 can be changed electronically via one or more actuators, which might be electronically coupled to the smartphone 161. In this way, it is possible to change the lenses or filters on the wheels 180 and 181 remotely or using the smartphone 161. In some implementations, results of
10 the refraction eye examination are sent to a host computer for evaluation and/or to order online prescription eyeglasses or contact lenses.

[34] The eye examination apparatus 100 described herein can be used to examine one eye at a time or two eyes at the same time. In some implementations, the eye examination apparatus 100 is equipped with at least one occlude, for example a pair of occluders. The
15 occluders can be used selectively block light for an eye that is not being examined. Additionally, or alternatively, the occluders can be used in differentiating vision impairment. An example of this is described below with reference to Figure 1o.

[35] Referring now to Figure 1o, shown is a schematic of the eye examination apparatus 100 having a pair of occluders 138. In some implementations, the occluders 138 are
20 optionally provided as additional attachments. The occluders 138 can either slide/swipe over the lenses 101 or can be placed directly on the lenses 101. In some implementations, the occluders 138 have a plurality of pinholes 139 (for example fifteen pinholes as depicted). The pinholes 139 are configured to eliminate disorganized refracted light arrays which cause blurred vision in non-neurological eye conditions. More precisely, the pinholes 139 assist in differentiating
25 vision impairment caused by neurological eye diseases such as multiple sclerosis, stroke, etc. versus non-neurological eye diseases such as refractive error, dry eye, etc. Moreover, the pinholes 139 are useful for testing visual acuity in cycloplegic eyes (state of the eye after paralyzing the pupil and lens muscles with specific eye drops) as they are can effectively reduce the intensity of incoming light.

30 **[36]** In some implementations, each occluder 138 is secured in place using a pin 140 attached to the front surface of the eye examination apparatus 100, which enables it to pivot down

- 12 -

when being used. In other implementations, the occluders 138 can be placed directly on or fitted over the lenses 101. Other implementations are possible.

[37] In some implementations, the first eye opening 101 and the second eye opening 102 of the eye examination apparatus 100 are separate openings as depicted. However, other implementations are possible in which the the first eye opening 101 and the second eye opening 102 are part of the same opening, namely a large opening that enables the user to see into the eye examination apparatus 100 using both eyes. In some implementations, the eye examination apparatus 100 has a middle wall 109 separating a left side for examining the user's left eye from a right side for examining the user's right eye.

[38] There are many possibilities of the body of the eye examination apparatus 100. In some implementations, the body includes a plastic material. In specific implementations, the body is generated using a 3D printer. The front cartridge 111 and the upper cartridge 110 can also be formed of a plastic material and generated using a 3D printer. In specific implementations, a user can use a 3D printer to generate the eye examination apparatus 100 themselves. In other implementations, the eye examination apparatus 100 is produced and distributed to the user by a manufacturer. Note that other materials such as cardboard can be used instead of (or in addition to) plastic. Factory produced head-mounted devices are also possible. Other implementations are possible.

[39] There are many possibilities for securing the eye examination apparatus 100 to the user. In some implementations, as described above, the eye examination apparatus 100 has a headband 112 and 113 for securing the eye examination apparatus 100 to the user. In other implementations, eye examination apparatus 100 is simply held by the user against their face. In some implementations, the eye examination apparatus 100 has a nose rest 175, which may help to facilitate the eye examination apparatus 100 to properly fit against the user's face. Other implementations are possible.

[40] Although the illustrated examples focus on a particular type of coupling for receiving smartphone(s), it is noted that other types of coupling are possible and are within the scope of the disclosure. Any suitable coupling that is able to receive and hold a smartphone in a predefined position such that its camera can acquire ophthalmic images through the first eye opening 101 and its display is viewable through the second eye opening 102 can be employed. Snap-fit implementations and/or other fixation means are possible without sliding cartridges as depicted.

- 13 -

Also, other positions for the couplings are possible. For example, as noted above, rather than the upper cartridge 110, the eye examination apparatus 100 could employ a lower cartridge (not shown). Other implementations are possible.

5 [41] Although the illustrated examples utilize the semi-transparent mirror 106 for reflection, it is noted that a semi-transparent prism can be utilized instead. It is noted that a semi-transparent prism could cause more refraction than the semi-transparent mirror 106, depending on geometry of course. It is implementation-specific whether a semi-transparent mirror or prism is utilized. In either case, light is enabled to pass through the semi-transparent mirror or prism, generally with line or sight, albeit with some amount of refraction. In specific implementations, as
10 shown in the illustrated examples, a semi-transparent mirror is oriented at 45-degree angle relative to the first smartphone and the second smartphone to facilitate reflections, given that the smartphones are orthogonal to one another. However, other geometries are possible and are within the scope of the disclosure.

[42] Referring now to Figure 1p, shown is a flowchart of a computer-implemented method
15 of performing an eye examination. This method can be executed by at least one processor, for example by a processor of one of the smartphones described above in relation to Figures 1a to 1o. In some implementations, the smartphone downloads and executes an app to enable the computer-implemented method described below.

[43] At step 1-1, the processor captures, using a camera of the smartphone, images of
20 a first eye of a user. At step 1-2, the processor displays, using a display of the smartphone, images for a second eye of the user. In some implementations, the computer-implemented method is performed with only one smartphone. This can enable an eye examination of one eye at a time. In other implementations, the computer-implemented method is performed with two smartphones, which can enable the eye examination of both eyes simultaneously.

25 [44] In some implementations, as shown at step 1-3, the processor captures, using a camera of a second smartphone, images of the first eye of the user. In some implementations, as shown at step 1-4, the processor displays, using a display of the second smartphone, images for the second eye of the user. In some implementations, as shown at step 1-5, the processor coordinates the first smartphone and the second smartphone to enable simultaneous capturing of
30 the images of the first eye and the second eye. This can help to facilitate the eye examination of both eyes simultaneously.

- 14 -

[45] In some implementations, the first smartphone and the second smartphone each have a wireless capability such as Bluetooth radio or Wifi connections, and coordinating the first smartphone and the second smartphone involves pairing (for example using the Bluetooth radios or Wifi radios) the first smartphone with the second smartphone to form a wireless Bluetooth or Wifi connection, and coordinating the first smartphone and the second smartphone using communication over the wireless connection. Other implementations are possible.

[46] In some implementations, the processor stores, in a memory of the first smartphone, the images of the first eye and the second eye. In other implementations, each smartphone stores its own images that have been acquired. In some implementations, as shown at step 1-6, the method involves transmitting, using a transmitter of the first smartphone, the images of the first eye and/or the second eye. The transmitted data can be sent to a clinician's office for example, such that the data can be assessed or examined by a clinician. In other implementations, each smartphone transmits its own data. Other implementations are possible.

[47] According to the computer-implemented method, it is possible for the user to have an eye examination performed remotely outside of a clinician's office without specialized equipment by instead using their own smartphone(s). This is an improvement over the currently available portable eye-examination devices. The eye examination apparatus 100 is relatively easy to use with one or two smartphones and therefore may be suitable for use by households, schools, paramedics, etc.

[48] In some implementations, AI (Artificial intelligence) and machine learning systems are adopted to analyze the ophthalmic images in order to recognize healthy from abnormal eye and visual structures and functions. All embodiments described herein can be equipped with this functionality. Use of AI can significantly help health professionals to narrow down a diagnosis and triage an urgent patient to emergency room or to a physician's office in a timely manner.

[49] According to another embodiment of the disclosure, there is provided a non-transitory computer readable medium having recorded thereon statements and instructions that, when executed by at least one processor, implement a method as described herein. The non-transitory computer readable medium can for example include an SSD (Solid State Drive), a hard disk drive, a CD (Compact Disc), a DVD (Digital Video Disc), a BD (Blu-ray Disc), a memory stick, or any appropriate combination thereof.

- 15 -

Professional Embodiments

[50] Referring now to Figure 2a, shown is a schematic of an eye examination apparatus 200 that can be used in a professional setting. Unlike the eye examination apparatus 100 described with reference to Figures 1a to 1p, the eye examination apparatus 200 of Figure 2a does not make use of existing smartphones, but rather is equipped with its own dedicated sensor modules 121 and 122 and at least one display 119 and 120. Still, the eye examination apparatus 200 of Figure 2a operates using similar principles as described above for the eye examination apparatus 100 of Figures 1a to 1p.

[51] There are many possibilities for the at least one display 119 and 120. In some implementations, as shown in the illustrated example, the at least one display 119 and 120 includes high-resolution display screens including a first display 119 positioned to be viewable through the first eye opening 101 and a second 120 display positioned to be viewable through the second eye opening 102. In other implementations, the at least one display 119 and 120 includes a single display having a left portion viewable through the first eye opening 101 and a right portion viewable through the second eye opening 102. Each of the displays 119 and 120 can be placed on an upper portion in the eye examination apparatus 200 as shown or on another portion such as the front wall in the eye examination apparatus 200. Other implementations are possible.

[52] There are many possibilities for the sensor modules 121 and 122. With reference to Figure 2b, each sensor module can for example include a pair of infrared or visible light projectors/sensors 123 and 124, at least one high resolution camera 125, and a laser emitter 126. Thus, each sensor module can have a capability of projecting laser beams, infrared light or visible light on a retina of an eye, the reflection of which being captured by the high-resolution cameras 125. The sensor modules 121 and 122 can be installed in a head-mounted device or in goggles. Other implementations are possible.

[53] Although the eye examination apparatus 200 is depicted with the sensor modules 121 and 122, it is noted that other implementations are possible in which there are no such modules. For instance, the eye examination apparatus 200 can be provided with a first camera coupled to the body and positioned to acquire ophthalmic images through the first eye opening 101, and a second camera coupled to the body and positioned to acquire ophthalmic images through the second eye opening 102. Such cameras can be provided without the infrared

- 16 -

projectors/sensors 123 and without the laser emitter 126. The cameras 125 can be installed in a head-mounted device or in goggles. Other implementations are possible.

[54] In some implementations, as shown in the illustrated example, (i) a first camera (e.g. camera 125 of the sensor module 121) is positioned to acquire ophthalmic images through the first eye opening 101 via line of sight through the semi-transparent mirror 106, and the first display 119 is viewable through the first eye opening 101 via reflection off of the semi-transparent mirror 106, and (ii) a second camera (e.g. camera 125 of the sensor module 122) is positioned to acquire ophthalmic images through the second eye opening 102 via line of sight through the semi-transparent mirror 106, and the second display 120 is viewable through the second eye opening 102 via reflection off of the semi-transparent mirror 106.

[55] In other implementations, (i) the first camera (e.g. camera 125 of the sensor module 121) is positioned to acquire ophthalmic images through the first eye opening 101 via reflection off of the semi-transparent mirror 106, and the first display 119 is viewable through the first eye opening 101 via line of sight through the semi-transparent mirror 106, and (ii) the second camera (e.g. camera 125 of the sensor module 122) is positioned to acquire ophthalmic images through the second eye opening 102 via reflection off of the semi-transparent mirror 106, and the second display 120 is viewable through the second eye opening 102 via line of sight through the semi-transparent mirror 120.

[56] Although the illustrated example depicts a semi-transparent mirror 106 for reflection, it is noted that a semi-transparent prism can be utilized instead. It is noted that a semi-transparent prism could cause more refraction than a semi-transparent mirror, depending on geometry of course. It is implementation-specific whether a semi-transparent mirror or prism is utilized. In either case, light is enabled to pass through the semi-transparent mirror or prism, generally with line of sight, albeit with some amount of refraction. In specific implementations, as shown in the illustrated examples, the semi-transparent mirror 106 is oriented at 45-degree angle relative to the sensor modules 121 and 122 and the at least one display 119 and 120 to facilitate reflections, given that the sensor modules 121 and 122 and the at least one display 119 and 120 are orthogonal to one another. However, other geometries are possible and are within the scope of the disclosure.

[57] In some implementations, the eye examination apparatus 200 is equipped with at least one condenser lens 154 for funduscopy, as similarly described above with reference to Figure 1i.

- 17 -

[58] In some implementations, the eye examination apparatus 200 is equipped with components for interferometry such as a low coherence light source 153a and a mirror 156 for OCT, as similarly described above with reference to Figure 1j. In some implementations, the eye examination apparatus 200 also has a lens 151 and a 2D MEMS mirror 155, as similarly described
5 above with reference to Figure 1i.

[59] In some implementations, the eye examination apparatus 200 is equipped with a refraction apparatus 188 for refraction eye examination, as similarly described above with reference to Figures 1k to 1n.

[60] In some implementations, the eye examination apparatus 200 is equipped with at
10 least one occlude, for example a pair of occludes, as similarly described above with reference to Figure 1o.

[61] In some implementations, the first eye opening 101 and the second eye opening 102 of the eye examination apparatus 200 are separate openings as depicted. However, other implementations are possible in which the the first eye opening 101 and the second eye
15 opening 102 are part of the same opening, namely a large opening that enables the user to see into the eye examination apparatus 100 using both eyes. In some implementations, the eye examination apparatus 200 has a middle wall 109 separating a left side for examining the user's left eye from a right side for examining the user's right eye.

[62] Referring now to Figures 2c to 2f, shown are perspective views of the eye
20 examination apparatus 200 implemented with a headband 130 and 131. In some implementations, the headband 130 and 131 includes an upper headband 130 and a lower headband 131 to enable the eye examination apparatus 200 to be worn as goggles. In some implementations, the eye examination apparatus 200 has a nose rest 175 for precise positioning of the goggles. In some implementations, the eye examination apparatus 200 is designed in a form of head-mounted
25 goggles to be used in professional establishments and clinics such as nursing stations, emergency rooms, and ophthalmology, neurology or optometry offices. Other implementations are possible.

[63] In some implementations, the eye examination apparatus 200 has a processing unit for controlling the first sensor module, the second sensor module, and the at least one display. In some implementations, the processing unit is configured to process ophthalmic images captured
30 by the high resolution cameras 125 and transmit them to a clinician for further analysis and

- 18 -

examination. In some implementations, the processing unit is disposed within a processor unit housing 129 on an upper portion of the eye examination apparatus 200. Other implementations are possible. In some implementations, the processing unit is an MCU (Microcontroller Unit), although other processors such as CPU (Central Processing Unit), FPGA (Field Programmable Gate Array), and ASIC (Application Specific Integrated Circuit) are possible.

[64] In some implementations, the eye examination apparatus 200 has adjustable lenses 132 for the first eye opening 101 and the second eye opening 102. The adjustable lenses 132 can enable the user to see the display screens 119 and 120 either via line of sight or via a 90-degree reflection off of the semi-transparent mirror 106, depending on how the eye examination apparatus 200 is implemented. The adjustable lenses 132 also facilitate capturing images of the eyes of the user using the high-resolution camera/scanner 125. Other implementations are possible.

[65] In some implementations, the eye examination apparatus 200 has at least one external sensor 128 configured to sense an environment external to the eye examination apparatus 200, and the processing unit controls the at least one display based on the at least one external sensor 128. In some implementations, the at least one external sensor 128 includes a pair of external cameras 128 configured to capture the environment external to the eye examination apparatus 200, and the processing unit generates images for the at least one display using the pair of external cameras 128. This can enable augmented reality.

[66] The eye examination apparatus 200 shown in Figures 2c to 2f is implemented with the headband 130 and 131 for securing the eye examination apparatus 200 to the user. In another implementation, the eye examination apparatus 200 is implemented with a helmet to be worn by the user. An example of this will be described below. Note that other securing means are possible and are within the scope of the disclosure.

[67] Referring now to Figures 2g to 2l, shown are perspective views of the eye examination apparatus 200 implemented with a helmet 134. In some implementations, the helmet 134 includes earphones 133 as well. In some implementations, the eye examination apparatus 200 has a nose rest 175 for precise positioning of the helmet. In some implementations, the eye examination apparatus 200 is designed in a form of head-mounted helmet to be used in professional establishments and clinics such as nursing stations, emergency rooms, and ophthalmology, neurology or optometry offices. Other implementations are possible.

- 19 -

[68] Referring now to Figures 3a to 3c, shown are perspective views of another eye examination apparatus 300 that can be used in a professional setting. Unlike the eye examination apparatus 200 described with reference to Figures 2a to 2l, the eye examination apparatus 300 of Figures 3a to 3c does not have eye openings for a user to see inside a region having displays/cameras, but rather is equipped with a visor having a transparent display 136 and camera assemblies 141. Still, the eye examination apparatus 300 of Figures 3a to 3c operates using similar principles as described above for the eye examination apparatus 200 of Figures 2a to 2l.

[69] In some implementations, the eye examination apparatus 300 is implemented with a helmet 135. In some implementations, the helmet 135 includes earphones 133 as well. In some implementations, the eye examination apparatus 300 is designed in a form of head-mounted helmet to be used in professional establishments and research labs and can be used by pilots, elite athletes, etc. Other implementations are possible.

[70] Each camera assembly 141 includes a camera. In some implementations, each camera assembly 141 includes a mirror or prism positioned to enable the camera to acquire ophthalmic images via reflection off of the mirror or prism. In some implementations, the camera assemblies 141 are retractable. In the illustrated example, the camera assemblies 141 in a deployed position, which enables the camera assemblies 141 to acquire ophthalmic images. However, when not in use, the camera assemblies 141 can be retracted into the eye examination apparatus 300.

[71] In some implementations, images displayed on the transparent display 136 are overlaid on a view of an environment that can be seen through the visor, thereby enabling augmented reality. In some implementations, the visor and the transparent display 136 are also retractable. In the illustrated example, the transparent display 136 in a deployed position, which enables the camera assemblies 141 to acquire ophthalmic images. However, when not in use, the camera assemblies 141 can be retracted into the eye examination apparatus 300.

[72] In some implementations, the eye examination apparatus 300 has a processing unit for the transparent display 136 and the camera assemblies 141. In some implementations, the processing unit is configured to process ophthalmic images captured by the camera assemblies 141 and transmit them to a clinician for further analysis and examination. In some implementations, the processing unit is disposed within a processor unit housing 137 on an upper portion of the eye examination apparatus 300. Other implementations are possible. In some

- 20 -

implementations, the processing unit is an MCU, although other processors such as CPU, FPGA, and ASIC are possible.

[73] In some implementations, the eye examination apparatus 300 has motion and/or position sensors, and the processing unit controls the transparent display 136 based on the motion and/or position sensors.

[74] In some implementations, the eye examination apparatus 300 is equipped with a refraction apparatus 188 for refraction eye examination, as similarly described above with reference to Figures 1k to 1n.

[75] In some implementations, the eye examination apparatus 300 is equipped with at least one occlude, for example a pair of occludes, as similarly described above with reference to Figure 1o.

Example Applications

[76] The eye examination apparatuses 100, 200 and 300 described herein have various applications as explained below. While many of these applications are described below in relation to the “smartphone embodiment” (i.e. the eye examination apparatus 100 depicted and described with reference to Figures 1a to 1p), it is to be understood that they can similarly be used in relation with the “professional embodiments” (i.e. the eye examination apparatus 200 depicted and described with reference to Figures 2a to 2l and/or the eye examination apparatus 300 depicted and described with reference to Figures 3a to 3c). Other applications maybe possible.

[77] *Visual Acuity:* A specifically designed mobile application can enable the eye examination apparatus and the primary and secondary DCSs to precisely define the visual acuity of the users using one of the well-established, reliable and currently used eye testing systems i.e. HOTV. The application can provide instructions to the patient via verbal and/or written instructions and upon confirmation provided by the user, it can prompt the user to put a primary and optionally a secondary DCS (smartphone) into their respective cartridge slots of the eye examination apparatus 100. A default test begins by testing the right eye unless the right eye is non-functional or chosen otherwise by the user or the examiner (optometrist/physician). Random selection of H, O, T or V letters with sizes equivalent to 20/50 on Snellen’s chart letters can be shown at a center of the display with a predetermined size reference letters at four sides. The user can then be prompted to respond if they recognize the letters and provide feedback in form of an eye or head

- 21 -

movement toward the correct reference letter, vocal response or touchscreen input. Upon correct answers for three consecutive presentations, the size of the letters can be reduced, and the test can repeat itself. Alternatively, the size of the letters can increase after two consecutive wrong answers in the first set of presentations. As the user recognizes the letters and correctly spots
5 them on the screen, the size of the target letters can be reduced. This process can continue until the user fails to provide three correct answers. A last letter size that the user is able to recognize reliably can be considered as their visual acuity. The cameras of the primary and secondary DCSs track the eyes during the visual acuity testing to ensure that the user gazed at the target.

[78] *Visual Field:* The application, the eye examination apparatus, along with the primary
10 and secondary DCSs, are also useful for performing automated visual field testing i.e. automated perimetry analysis. The patients or the examiners can determine a density and a span of a peripheral visual field to test. They can either choose to test a narrow span of the visual field (i.e. around the center of the vision) with high density test targets or a larger span of visual field with a variable density of test targets. Using a statistical model, brightness and locations of target lights
15 can be randomly determined and the test gradually becomes harder/complex until a defined brightness/contrast threshold is reached at any tested peripheral target points. This analysis allows diagnosis of various neurological diseases based on the unique patterns of visual loss, for example, the inferior nasal visual field loss in glaucoma. Capturing and studying the pattern of visual loss can help the artificial intelligence and the examiner/physician to improve speed and precision of
20 diagnosis. Results obtained can be conveniently stored in a secure system for further analysis and follow-up.

[79] *Color Vision:* The eye examination apparatus can be employed to perform a standard color deficiency test. Numbers with different colors are shown to the patient and patient's feedback is collected and analyzed to detect different types of color blindness.

[80] *Amsler Grid:* Amsler grid test is a screening test used to detect signs of diseases
25 that damage retina or the optic nerve. Some examples of these conditions include Age Related Macular Degeneration, retinal detachment and optic neuritis all of which can lead to permanent blindness if not treated. Early detection and intervention are crucial in successful treatment of these conditions which emphasize the importance of screening tests in detection and management of
30 these potentially disabling conditions. A grid of black lines spanning 20-30 degrees of the central field of vision is shown to each eye and the patient is asked to report any imperfection or distortion

- 22 -

in the grid lines. Presence of imperfections prompts the physician to perform more thorough examinations leading to early diagnosis and treatment of the above-mentioned conditions.

[81] *Eye tracking:* The cameras of the primary and secondary DCSs and the application are equipped with eye-tracking features. This is especially useful for detection and analysis of conditions that affect eye movement such as concussion, multiple sclerosis, traumatic brain injury, and neurodegenerative brain diseases (for example, Alzheimer's disease, Parkinson's disease, Fronto-Temporal Dementia. Using the eye-tracking feature, the eye examination apparatus can examine patients' eye movements while performing tasks such as self-paced saccades or smooth pursuit to further analyze the course of the disease and assess the effectiveness of the treatments.

[82] With advancement in smartphone and mobile technology, display resolution and camera resolution continue to improve which can improve visual acuity testing and other eye measurements by the eye examination apparatus.

[83] Various other applications of the eye examination apparatus include observation and analysis of:

- afferent and efferent visual functions;
- static eye features: eyelids, eyelid fissures, irises, pupil shape and size, pupil color and sclera.
- dynamic eye features: blinking, opening and closure of the eyes, pupil changes to light and near/far vision, regularity of the pupil reactions, and various eye movements,
- testing the dry eye syndrome (or equivalent eye abnormalities e.g. computer-eye syndrome etc.)
- testing the refraction of the eyes to define the prescription of glasses;
- optic nerve, retina and their vascular features; and
- refraction measurement for other purposes.

[84] Further, the eye examination apparatus can be employed to perform a variety of routine eye examinations to diagnose and assess common to severe eye conditions, a few of which are explained briefly hereunder.

- 23 -

Afferent Visual System (AVS)

[85] AVS is related to all visual and brain functions that are responsible for capturing the images from the environment and analyzing them in order to create visual perceptions. AVS is measured through different visual attributes including visual acuity, visual field, color vision, stereovision, depth perception, pupil size/shape in reaction to light and/or distance, and the integrity of peripheral vision such as Amsler grid test.

[86] *Visual acuity:* Visual acuity test is a measure of visual clarity at the center of vision (occasionally visual acuity is measured at peripheral vision as well). The clarity of vision is compared to the average visual clarity in the normal population which is called visual acuity. Different methods at different distances are used to test visual acuity, such as E-Chart, stylized letters, Landolt rings, pediatric symbols, or symbols for the illiterate. The standard measure of reporting normal visual acuity are 6/6 or 20/20, in Europe and North America, respectively. 20/20 or 6/6 vision means that the observer can clearly see a target at 20 feet (or 6 meters) (representing the nominator) as can a person with average normal vision (represented by denominator). However, if someone has reduced vision, for example 6/12 or 20/40, it means that the person can see a target clearly at 6 meters (20 feet) whereas an individual with average normal vision can see the same size object at 12 meters (40 feet).

[87] Traditionally with E-chart visual acuity testing the size of the letter that needs to be seen clearly to represent 20/20 vision was determined to be 5 arc minutes (1 arc minute is 1/60 of a degree of visual angle). The letter E has 3 sequences of dark and bright lines that need to be distinguished before the observer can clearly recognize the letter and its direction. More recently, the HOTV method of visual acuity testing has become a standard test. The HOTV system contains the letters (H, O, T, and V) which involves distinction of 3 repetition of light and bright pixels before the letter is distinguished. Therefore, vision with clarity of recognizing an image at 1.6 arc minute (the letters representing 20/20 vision) can recognize HOVT letters. As such the majority of commercially available cellphones since 2012 (over 70 cellphone models-see cellphone table) can provide close or above 37.5 PPD (pixel per degree) (representing 1.6 arc minute at Eye examination apparatus resolution and can be used to test 20/20 vision with HOTV system).

[88] *Visual field and peripheral vision:* Peripheral vision is a fundamental part of vision that provides awareness of the environment that can prevent accidents, collisions with objects approaching from the corners of the vision, etc.

- 24 -

[89] Measuring the visual field can be performed during an eye examination by a physician i.e. confrontation visual field test, which is neither sensitive nor specific. Alternatively, visual field testing can be done automatically by a physician or optometrist most commonly at a doctor office where the individual sits in front the machine and fixates at the center of the visual field; depending on the model of the visual field test machine the visual stimuli either is moved or flashed manually or by the machine at different areas of the visual field; visual stimulation is usually a dot of light. The patient responds to seeing the light by notifying the examiner or clicking a button. Sophisticated automatic visual tests use statistical models to increase the reliability as well as reduce the duration of the tests. These tests can now be performed virtually using the eye examination apparatus.

[90] *Color vision:* Color vision is defined as the ability of visual system to discriminate between different wavelengths of light within visible light spectrum regardless of its intensity¹. Humans are able to see colors due to the presence of cone retinal photoreceptors. Their peak sensitivity varies in three ranges of short (~535 nm) medium (~565 nm) and long (~440 nm) wavelengths. Hence, they are called S, M and L photoreceptors². Color blindness is a condition in which colors are not perceived properly. It can happen due to loss of cones (dichromacy), changes in spectral sensitivity of cones (anomalous trichromacy) or damage to the optic nerve or visual cortex. These could happen genetically or due to diseases or toxin-induced insults to the retinal, optic nerve or cortical cells³.

[91] *Stereovision, depth perception and stereoscopic display:* Stereoscopic display, also called 3D display or head-mounted display (HMD) comprises a visual display e.g. LCD or LED display, in front of each eye that works based on the principle of stereopsis⁴. It operates by showing slightly different 2D perspectives of the same object to each eye. The minor deviation of the object between the images is precisely equal to the natural perspective of the binocular vision. This deviation creates an illusion of a 3D environment⁵ and helps vision in its depth perception.

- 25 -

[92] *Pupillary response:* Pupils respond to near/far objects and light by contraction and relaxation. These are called near/light pupil response. In the near response, pupils contract because the human lens naturally distorts light near its periphery. Pupils naturally constrict in near object vision to avoid this distortion and enhance visual clarity⁶. Pupils constrict in response to bright light to reduce the amount of light entering the eye.

Efferent visual system (EVS)

[93] Efferent visual system (EVS) functions relate to all visual and brain functions that are related to eye movements, reflexes and alignment. EVS assessment includes measuring eye alignment/misalignment, saccadic/pursuit eye movements and the eye movement components. These components include saccade amplitude, accuracy, maximum speed, and number of saccades in self-paced, memory-based and reflexive (i.e. visually targeted) saccades. Moreover, EVS measurements include abnormal eye movements such as nystagmus/oscillation/intrusions of the eye at neutral or different gaze positions, and eye reflexes such as vestibulo-ocular-reflex (VOR) and inhibition (VOI).

[94] *Pursuit eye movement:* Smooth pursuit eye movements are slower than saccades and evolved to fixate on a moving object at the center of vision i.e. when the image is fallen on the fovea⁷. This movement is under voluntary control. However, in the absence of an object only highly trained individuals are able to make smooth pursuits eye movements and most of the people will simply perform saccades⁸. Smooth pursuit is highly controlled by the brain (frontal eye field in the frontal lobe).

[95] *Saccade:* A saccade is defined as a synchronous and rapid movement of the eyes between two points⁹. In comparison to VOR response that is controlled by a relatively

- 26 -

straightforward pathways, saccadic response is driven by complex and polysynaptic pathways that originate from the frontal eye field (FEF) cerebellum, or superior colliculus¹⁰.

[96] *Self-paced Saccade*: Self-paced saccade (SPSs) is defined as a voluntary saccade between two fixed targets. The anterior cingulate cortex is responsible for maintaining the motivation to perform the task. The FEF, prefrontal cortex (dorsolateral part) and superior colliculus of the midbrain constitute the pathways that govern self-paced saccades^{11,12}. More precisely, to generate a horizontal saccade initiation, signals from the FEFs are sent to paramedian reticular formation in pons to activate cranial nerve 6 nucleus. Further, the signal will continue to go to midbrain from Medial Longitudinal Fasciculus (MLF) to activate cranial nerve 3 nucleus. These 2 cranial nuclei are fundamentally responsible for horizontal eye movements. The vertical saccade is generated by initiation signals from FEFs transmitted to the rostral interstitial nuclei of MLF, 3rd and 4th cranial nerves^{13,14} which in turn generate and control vertical eye movements.

[97] Studies on mTBI patients have revealed impairments of several characteristics of horizontal SPSs such as total number of saccades and intersaccadic intervals¹⁵. Patients with mTBI performed fewer SPSs with a significantly increased intersaccadic interval which indicates impairment of the prefrontal function^{16,17}. In addition to the parameters mentioned above, other parameters such as saccadic velocity to accuracy ratio (S/A ratio) and saccade gain are among

- 27 -

common metrics to evaluate horizontal saccadic performance^{18,19}. Studies have also demonstrated impairment in vertical saccadic performance such as efficiency, amplitude, peak, acceleration and position errors following mTBI²⁰.

[98] *Reflexive (visual targets) saccades*: Reflexive saccades are defined in relation to voluntary saccades. While the latter involve voluntarily controlled cognitive processes, reflexive saccades occur in response to the appearance of a new target eccentric to the point of fixation²¹.

[99] *Memory based saccade*: Memory-guided saccade is defined as a saccade to the place of a target that flashed briefly. This involves remembering the location of the briefly visible target. A defect in the basal ganglia or frontal lobes where working memory is processed, results in memory guided saccade dysfunction²².

[100] *Saccade velocity*: Most frequently measured velocity parameter is peak saccade velocity. It is defined as the maximum speed of the eyes during a saccade. The typical peak velocity of saccades in a normal person ranges from 30 to 700 degrees/s with an amplitude between 0.5 to 40 degrees²³. Changes in peak saccade velocity could be a viable indicator of psychophysiological arousal (sympathetic nervous system activation), mental activity workload or prediction of the subsequent fixation point value^{24,25,26}.

- 28 -

[101] *Time to peak velocity:* As previously described, saccadic peak velocity is defined as the maximum velocity reached during a saccade. The time spent between the beginning of the saccade until reaching the peak of velocity is called time to peak velocity.

[102] *Saccade accuracy, latency and amplitude:* Saccade accuracy is the accuracy with which a saccade fixates a target on the center of fovea. Average landing error and average landing variability are two parameters that are used to measure accuracy and precision of the saccades respectively²⁷. Studies have shown that even small saccades (between 14 to 20 degrees) are accurate enough to precisely center the stimulus on the fovea²⁸. Studies have demonstrated alterations in saccadic accuracy following mild traumatic brain injury²⁹. This indicates the potential of these parameters for the diagnosis and follow up of the patient suffering from mTBI.

[103] *Saccade gain:* Saccade gain is calculated based on the saccade amplitude and is a parameter that is used to measure saccade accuracy. This parameter defines if the saccade is hypo- or hypermetric and calculated by dividing the actual saccade amplitude by desired saccade amplitude³⁰.

[104] *Position error:* Is a parameter to measure the motor accuracy of saccades. It is closely related to saccade gain. The mean absolute position error measures the difference between desired and actual eye position. However, saccade amplitude clarifies the direction of that error by showing whether there was a hypo- or hypermetria. These parameters are effective means of measuring the impact of TBI on saccadic eye movements³¹. "Mean absolute position error of the final eye position [$PE_{reflexive} = |(EP_{fin} - SP)/SP| \times 100$], gain of the primary saccade ($G_p = EP_{prim}/SP$) and gain of the final eye position ($G_f = EP_{fin}/SP$), where EP_{prim} is the eye position after the initial saccade, EP_{fin} is the final eye position and SP is the stimulus position"³².

[105] *Saccadic intrusions:* Saccadic intrusions are defined as saccades that interrupt fixation. They happen irregularly and categorized based on whether or not they are separated by a brief interval of fixation. Some examples of the saccades that possess an intersaccadic interval include square wave jerks, macro-saccadic oscillations and macro square wave jerks. Among
5 those that happen as back-to-back saccades without any intersaccadic interval, are opsoclonus, voluntary nystagmus and ocular flutter³³. While saccadic intrusions could be found in normal individuals, they could also indicate underlying disorders/dysfunction of brainstem, cerebellum, superior colliculus, basal ganglia or cerebellum.

[106] *Vestibulo-ocular reflex and inhibition:* Vestibulo-ocular reflex (VOR) is a 3-
10 dimensional reflex governed by the inner ear vestibular system and involves cranial nerves III, IV, VI, VIII, their respective nuclei, as well as medial longitudinal fasciculus (MLF) to maintain visual stability during head movement. VOR stabilizes gaze by moving the eye to the opposite direction from the head movement. A defect in the vestibular system, the associated nuclei or their interconnecting pathways could lead to a dysfunctional VOR³⁴. Conversely, the Vestibulo-ocular
15 inhibition (VOI) demonstrates the ability of the EVS to inhibit VOR when the head follows a moving object by rotating the whole body and keeping the eye stationary and fixated on the target.

[107] *Dynamic visual acuity:* Maintaining visual acuity during head movement (dynamic visual acuity) is the outcome of an interplay between vestibular, visuomotor and visual systems³⁵. Normally, there is a certain degree of reduction in visual acuity during movement. Reduction of
20 visual acuity during movement beyond its normal range (oscillopsia) indicates a non-compensated insult to the pathways responsible for VOR³⁶. Recent studies have established a relationship between recovery of dynamic visual acuity parameters and improvement of post-concussion syndrome³⁷.

- 30 -

[108] *Nystagmus*: Nystagmus is defined as involuntary eye movement in a horizontal, vertical or rotatory fashion. Based on movement speed, two types of nystagmus could be distinguished from each other³⁸. Pendular nystagmus is a type that consists of slow sinusoidal oscillations in both phases while Jerk nystagmus is characterized by a slow drift and a rapid
5 corrective saccade³⁹.

[109] Proper characterization of nystagmus helps with the diagnosis of causative defects and pathologies. The first step in finding the cause of the nystagmus is to determine the effect of removing the fixation on the severity of the nystagmus. As an example, increasing the severity of nystagmus after removing fixation indicates a peripheral origin⁴⁰. A peripheral nystagmus that is
10 caused by a peripheral vestibular pathology usually causes a jerk nystagmus that beats away from the side of the lesion. In contrast, a congenital nystagmus is usually horizontal and accentuated by fixation as well as anxiety⁴¹. Moreover, presence of a purely torsional or vertical jerk nystagmus while the eyes are at a near center position mainly indicates a central lesion involving the vestibular pathways⁴².

15 Structure of the Visual System

[110] The measurements include (1) optic nerve thickness and shape, (b) retina/macula layers, thickness and shape and (3) vascular structure and live function and reaction of the vessels to different maneuvers for example Valsalva or fast breathing or visual stimulation such as stationary vs motion pictures. Ocular coherence tomography technology will be placed at the
20 display and cameras which can demonstrate microstructure of the optic nerve, retina and their vessels.

Virtual reality (VR)

[111] A platform through which a computer generated 3D rendered environment is presented to the viewer using one or more stereoscopic displays combined with a plethora of novel technologies such as head and eye tracking sensors, software frameworks, development tools and input devices packaged in a head-mounted setup designed to create an illusion of reality. Input devices enable the user to interact with the virtual environment⁴³.

Eye tracking

[112] Eye tracking is an objective method of assessing ocular function. Eye tracking systems and softwares are designed to measure different aspects of ocular motor function including movement, position, latencies, frequency of moves, etc.⁴⁴. It also measures the pattern of eye movements between the fixation points including saccade amplitude (in degrees), speed, number of saccades^{45,46}, etc. Position measures calculate the Cartesian coordinates of the gaze and latency measures quantify the duration of saccades and fixations (defined as pause at a spatial location for more than 99 milliseconds). Moreover, the quantity of saccades and number for fixations and blinks are among mostly studied frequency measures⁴⁷.

[113] A typical eye tracking setup consists of an infrared or semi-infrared light source, a camera and a software that processes the images and tracks the eye movement mainly through pupil tracking⁴⁸. More sophisticated tracking systems include light emitters to produce light

reflections on the eye surface. The relative position of the reflected points to the pupil will be used to calculate the eye position vectors and point of regard⁴⁹.

Diseases that the Eye Examination Apparatus can Help with Diagnosis and Monitoring Recovery

[114] Another disease that the eye examination apparatus can help with diagnosis and monitoring the recovery is Mild traumatic brain injury (mTBI). Proper eye movement relies extensively on the functional integrity of the brain and its pathways. Moreover, attention, response inhibition, memory, motor planning and speed of information processing play significant roles in the control of eye movements. Studies have established a significant correlation between mTBI and impairment of EVS⁵⁰. Interestingly, the eye movement deficits happen independent of neuropsychological symptoms of mTBI⁵¹. Meta-analysis of studies focused on neuropsychological sequelae of mTBI demonstrated that neurocognitive determinants of the post-concussion syndrome completely resolve 1-3 months after the impact. Moreover, imaging entities have limited ability in detecting abnormalities in patients with post-concussion syndrome^{52,53}.

[115] The assessment of EVS and AVS abnormalities through the eye examination apparatus can prove useful in identifying many eye and brain disorders such as: a. Eye diseases such as macular degeneration, glaucoma, optic neuropathy, etc. (AVS abnormalities); b. Neurodegenerative diseases like Parkinson disease, Alzheimer disease, etc.; c. Psychiatric diseases such as schizophrenia, ADHD, etc. (AVS and EVS abnormalities); d. Common eye conditions such as amblyopia.

- 36 -

We Claim:

1. An eye examination apparatus for use with at least one smartphone, comprising:
a body having a first eye opening and a second eye opening for a user to see into the eye examination apparatus using two eyes;

5 a coupling for receiving a smartphone having a display and a camera and for holding the smartphone in a predefined position in relation to the body, such that the camera of the smartphone is positioned to acquire ophthalmic images through the first eye opening, and the display of the smartphone is viewable through the second eye opening.

2. The eye examination apparatus of claim 1, wherein the coupling enables positioning
10 of the smartphone such that the camera can acquire the ophthalmic images through the first eye opening via line of sight and the display of the smartphone is viewable through the second eye opening via line of sight.

3. The eye examination apparatus of claim 2, wherein the coupling is a first coupling, the smartphone is a first smartphone, and the eye examination apparatus further comprises:

15 a semi-transparent mirror or prism coupled to the body; and

a second coupling for receiving a second smartphone having a display and a camera and for holding the second smartphone in a predefined position in relation to the body, such that the camera of the second smartphone is positioned to acquire ophthalmic images through the second eye opening via reflection off of the semi-transparent mirror or prism, and the display of the
20 second smartphone is viewable through the first eye opening via reflection off of the semi-transparent mirror or prism;

wherein the semi-transparent mirror or prism is positioned to enable the reflections for the second smartphone but is transparent enough to enable the line of sight for the camera and the display of the first smartphone through the semi-transparent mirror or prism.

25 4. The eye examination apparatus of claim 3, wherein the first coupling and the second coupling are configured to hold the first smartphone and the second smartphone orthogonally to one another, and the semi-transparent mirror or prism is a semi-transparent mirror oriented at 45-

- 37 -

degree angle relative to the first smartphone and the second smartphone to facilitate the reflections for the second smartphone.

5. The eye examination apparatus of claim 4, wherein the second coupling is configured to hold the second smartphone on a top portion of the body.

5 6. The eye examination apparatus of claim 4, wherein the second coupling is configured to hold the second smartphone on a bottom portion of the body.

7. The eye examination apparatus of any one of claims 3 to 5, wherein:

the first coupling comprises a first cartridge that holds the first smartphone, such that the first cartridge is slidably insertable into the body; and

10 the second coupling comprises a second cartridge that holds the second smartphone, such that the second cartridge is slidably insertable into the body.

8. The eye examination apparatus of any one of claims 3 to 6, further comprising:
a pair of convex lenses for the first eye opening and the second eye opening.

9. The eye examination apparatus of claim 8, wherein the pair of convex lens is a first
15 pair of convex lens, and the eye examination apparatus further comprises:

a second pair of convex lens for the camera of the first smartphone and the camera of the second smartphone.

10. The eye examination apparatus of any one of claims 3 to 9, further comprising:

at least one light emitter positioned to generate infrared or visible light out of the first
20 eye opening and the second eye opening via reflection off of the semi-transparent mirror or prism.

11. The eye examination apparatus of claim 10, wherein the at least one light emitter comprises a first infrared emitter positioned to generate infrared light out of the first eye opening and a second infrared emitter positioned to generate infrared light out of the second eye opening.

12. The eye examination apparatus of any one of claims 3 to 11, further comprising at
25 least one condenser lens configured to render a divergent beam from a light emitter of the second

- 38 -

smartphone into a converging beam for funduscopy involving image capturing by the camera of the first smartphone.

13. The eye examination apparatus of any one of claims 3 to 12, further comprising at least one condenser lens configured to render a divergent beam from a light emitter of the first smartphone into a converging beam for funduscopy involving image capturing by the camera of the second smartphone.

14. The eye examination apparatus of any one of claims 3 to 11, further comprising:
components for interferometry including a low coherence light source and a mirror;
and

wherein the low coherence light source is positioned facing the mirror through the semi-transparent mirror or prism, such that low coherence light from the low coherence light source can be split by the semi-transparent mirror or prism into a reference light wave through the semi-transparent mirror or prism and a sample light wave reflected off of the semi-transparent mirror or prism; wherein the reference light reflects off of the mirror, reflects off of the semi-transparent mirror or prism, and is received by the camera of the first smartphone; wherein the sample light wave light reflects off of a sample, passes through the semi-transparent mirror or prism, and is received by the camera of the first smartphone; wherein the camera of the first smartphone is positioned to detect interference between the reference light wave and the sample light wave.

15. The eye examination apparatus of claim 14, wherein the components for interferometry further comprises a 2D MEMS (Microelectromechanical) mirror for beam steering the sample wave and a lens to condense the the sample wave into a converging beam at the sample.

16. The eye examination apparatus of any one of claims 1 to 11, further comprising refraction apparatus for refraction eye examination.

17. The eye examination apparatus of claim 16, wherein the refraction apparatus is selectively attachable to the eye examination apparatus.

18. The eye examination apparatus of any one of claims 1 to 17, further comprising at least one occluder.

- 39 -

19. The eye examination apparatus of claim 18, wherein the at least one occluder comprises a pair of occluders each having a plurality of pinholes configured to eliminate disorganized refracted light arrays which cause blurred vision in non-neurological eye conditions.

20. The eye examination apparatus of any one of claims 1 to 19, wherein the first eye
5 opening and the second eye opening are separate openings.

21. The eye examination apparatus of any one of claims 1 to 20, wherein the body comprises a plastic material.

22. The eye examination apparatus of any one of claims 1 to 21, further comprising a headband for securing the eye examination apparatus to the user.

10 23. A computer-implemented method of performing an eye examination, comprising:

capturing, using a camera of a smartphone, ophthalmic images of a first eye of a user; and

displaying, using a display of the smartphone, images for a second eye of the user.

24. The computer-implemented method of claim 23, wherein the smartphone is a first
15 smartphone, and the method further comprises:

capturing, using a camera of a second smartphone, ophthalmic images of the first eye of a user; and

displaying, using a display of the second smartphone, images for the second eye of the user.

20 25. The computer-implemented method of claim 24, further comprising:

coordinating the first smartphone and the second smartphone to enable simultaneous capturing of the ophthalmic images of the first eye and the second eye.

26. The computer-implemented method of claim 25, further comprising:

storing, in a memory of the first smartphone, the ophthalmic images of the first eye
25 and the second eye.

- 40 -

27. The computer-implemented method of claim 25 or claim 26, wherein the first smartphone has a transmitter, and the computer-implemented method further comprises:

transmitting, using the transmitter of the first smartphone, the ophthalmic images of the first eye and/or the second eye.

5 28. The computer-implemented method of any one of claims 25 to 27, wherein the first smartphone and the second smartphone each have a Bluetooth radio, and coordinating the first smartphone and the second smartphone comprises:

pairing, using the Bluetooth radios, the first smartphone with the second smartphone to form a Bluetooth connection; and

10 coordinating the first smartphone and the second smartphone using communication over the Bluetooth connection.

29. The computer-implemented method of any one of claims 25 to 27, wherein the first smartphone and the second smartphone each have a Wifi radio, and coordinating the first smartphone and the second smartphone comprises:

15 pairing, using the Wifi radios, the first smartphone with the second smartphone to form a Wifi connection; and

coordinating the first smartphone and the second smartphone using communication over the Wifi connection.

30. A non-transitory computer readable medium having recorded thereon statements
20 and instructions that, when executed by at least one processor, cause the at least one processor to perform a method for eye examination in accordance with any one of claims 23 to 29.
