A method of delivering warp yarn into an air jet loom, comprising the steps of: providing a loom beam comprising warp yarn having a resin compatible coating; drawing warp yarn from the loom beam; contacting the warp yarn with a whip roll having a reduced surface area such that the warp yarn contacts at least a portion of the reduced surface area of the whip roll; and directing the warp yarn into an air jet loom. In one non-limiting embodiment of the invention, the reduced surface area of the whip roll is no greater than 50% of its equivalent surface and is textured, the reduced surface area of the whip roll includes a plurality of grooves, the warp yarn is a fine yarn provided at a warp yarn density of at least 50 yarns per inch and forms a warp shed, and a fill yarn having a resin compatible coating is inserted into the warp shed.

19 Claims, 2 Drawing Sheets
WHIP ROLL FOR AIR JET LOOM WEAVING OF RESIN COMPATIBLE YARN

FIELD OF THE INVENTION

The present invention relates to an air jet loom, and in particular to weaving yarns having a resin compatible coating on an air jet loom.

BACKGROUND OF THE INVENTION

Air jets looms are widely used for high speed fabric weaving. Typically, a plurality of warp yarns are wound around a loom beam positioned at one end of the air jet loom. The warp yarns are unwound from the loom beam and extend the length of the loom. A whip roll is positioned to support the sheet of warp yarns as it advances to the weaving position of the loom and ensure that the yarn is delivered to the loom at the same weaving angle as the loom beam diameter changes during weaving. The whip roll also maintains the proper tension in the warp yarn during the weaving operation. One or more weft yarn feed systems deliver, i.e., insert, weft yarn into a shed formed by warp yarns using a main air jet nozzle assisted by groups of relay nozzles disposed across the warp shed, as is well known to those skilled in the art.

Depending in the nature of the warp yarn, problems can occur as the yarn is delivered from the loom beam to the loom. For example, the warp yarn can to move and roll laterally along the whip roll. This, in turn, can result in adjacent warp yarn strands becoming entangled and twisted together as they advance into the loom. If the yarns break as they enter the loom, the weaving operation will stop. To address this problem, grooved whip rolls have been used to stabilize the warp shed. It has been observed that this rolling and entanglement problem is of particular concern where the weaving operation uses warp yarn having a resin compatible coating. These coatings are typically tacky, which adds to the potential for the yarns to stick together and break as they enter the loom. It has been further observed that fine yarns, e.g., E-225 and D-450 yarns, with resin compatible coatings that are used as warp yarn in a weaving operation exhibit a greater potential to become entangled because of the higher warp yarn density associated with such fabrics.

It would be advantageous to provide a weaving system that ensures continuous, uninterrupted feed of the warp yarn having a resin compatible coating.

SUMMARY OF THE INVENTION

The present invention provides a method of delivering warp yarn into an air jet loom, comprising the steps of: providing a loom beam comprising warp yarn having a resin compatible coating; drawing warp yarn from the loom beam; contacting the warp yarn with a whip roll having a reduced surface area such that the warp yarn contacts at least a portion of the reduced surface area of the whip roll; and directing the warp yarn into an air jet loom. In one non-limiting embodiment of the invention, the reduced surface area of the whip roll is no greater than 50% of its equivalent surface and is textured, the reduced surface area of the whip roll includes a plurality of grooves, the warp yarn is a fine yarn provided at a warp yarn density of at least 50 yarns per inch and forms a warp shed, and a fill yarn having a resin compatible coating is inserted into the warp shed.

The present invention further provides a fabric made according to the above described method.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic isometric view of an air jet loom incorporating features of the present invention.
Referring to FIG. 2, the whip roll 26 is configured to have a reduced roll surface so as to reduce the physical contact between the warp yarn 22 and the surface of the roll 26. In one non-limiting embodiment of the invention, the surface of roll 26 includes a plurality of grooves 44 such that the yarn 22 contacts only surface portions 46 of the roll 26. This type of roll is also referred to as a flushed roll. The grooves 44 can have any configuration that is effective in reducing the surface area of the whip roll 26 which contacts the yarn 22. Although not required, it is preferred that surface portion 46 be no greater than 50% of the equivalent surface 44 of the whip roll 26, and more preferably no greater than about 25% of the equivalent surface 48. As used herein, the term “reduced surface area” means that portion of roll 26 that can physically contact the yarn 22, and the term “equivalent surface” means the total surface of a cylindrically shaped whip roll without any removal of the roll surface. For example and referring to FIG. 2, if a cylindrically shaped whip roll 26, without grooves 44, has a radius R of 3 inches (7.62 cm), the equivalent surface 48 would be 18.8 inch² per inch of length of the roll (47.9 cm²/cm of length). Furthermore, if the roll 26 included eight similar grooves each having a chord length C along the surface of the roll 26 of 1/8 inch, the reduced surface area, i.e. surface portion 46, would be about 7.75 inch² per inch of length of the roll (19.7 cm²/cm of length), or about 41% of the equivalent surface 48.

Although the particular embodiment of the whip roll 26 illustrated in FIGS. 1 and 2 shows the grooves 44 being equally spaced about the circumference of the roll 26 and generally parallel to each other, these details of the roll are not required. More specifically, it is contemplated that the grooves need not be equally spaced apart from nor be parallel to each other. It is further contemplated that in one non-limiting embodiment of the invention, the whip roll includes one or more sets of spiraling grooves, e.g. a first set of grooves spiraling in one direction around whip roll and a second set of grooves spiraling in a direction opposite that of the first set of grooves.

Although not required, it is preferred that the surface portion 46 of whip roll 26 be treated or coated with a material that provides a textured surface, e.g. a roughened or matte finish. It is believed that this textured surface reduces the friction between the warp yarn 22 and surface portion 46 of the whip roll 26 as compared to a smooth surface because there is less physical contact between a surface portion 46 and the yarn 22, so that the yarn 22 can slide along the surface portion 46. This reduction in contact at a surface portion 46 in combination with reduced total surface of the whip roll 26, reduces the potential of the yarn 22 to roll and move along the whip roll surface and become entangled with adjacent yarn strands 22. Although not limiting in the present invention, surface portions 46 can be treated by sandblasting, etching or applying a coating to provide the desired textured surface. In another non-limiting embodiment of the invention, the whip roll 26 is made of metal, e.g. aluminum, and surface portions 46 are provided with a roughened, or matte, finish.

As discussed earlier, the present invention is particularly applicable for yarns comprising glass fibers coated with a coating that is compatible with a resin matrix material into which the yarn is incorporated. As used herein, the terms “compatible with a resin matrix material” or “resin compatible” mean the coating composition applied to the glass fibers is compatible with the resin matrix material into which the glass fibers will be incorporated such that the coating composition (or selected coating components) achieves at least one of the following properties: does not require removal prior to incorporation into the matrix material (such as by de-greasign or de-oiling), facilitates good penetration of the matrix material through the individual bundles of fibers in a mat or fabric incorporating the yarn and good penetration of the matrix material through the mat or fabric during conventional processing and results in final composite products having desired physical properties and hydrolytic stability.

Without limiting the present invention, one embodiment of the resin compatible coating composition on the glass fibers comprises one or more, and preferably a plurality of particles that when applied to the fibers adhere to the fibers and provide one or more interstitial spaces between adjacent glass fibers. Nonlimiting examples of preferred particles include hexagonal boron nitride and hollow styrene acrylic polymeric particles.

In addition to the particles, a nonlimiting embodiment of the resin compatible coating composition preferably comprises one or more film-forming materials, such as organic, inorganic and polymeric materials. Nonlimiting examples of film-forming materials include vinyl polymer, such as, but are not limited to, polyvinyl pyrrolidones, polyesters, polyamides, polyurethanes, and combinations thereof.

In addition to or in lieu of the film forming materials discussed above, a nonlimiting embodiment of the resin compatible coating compositions can include one or more glass fiber coupling agents such as organo-silane coupling agents, transition metal coupling agents, phosphonate coupling agents, aluminum coupling agents, amino-containing Werner coupling agents and mixtures thereof.

A nonlimiting embodiment of the resin compatible coating compositions can further comprise one or more softening agents or surfactants. Nonlimiting examples of softening agents include amine salts of fatty acids, alkyl imidazoline derivatives, acid solubilized fatty acid amides, condensates of a fatty acid and polyethylene imine and amide substituted polyethylene imines.

A nonlimiting embodiment of the resin compatible coating compositions can further include one or more lubricious materials that are chemically different from the polymeric materials and softening agents discussed above to impart desirable processing characteristics to the fiber strands during weaving. Nonlimiting examples of such fatty acid esters useful in the present invention include cetyl palmitate, cetyl myristate, cetyl laurate, octadecyl laurate, octadecyl myristate, octadecyl palmitate and octadecyl stearate. The lubricious materials can also include non-polar petroleum waxes and water-soluble polymeric materials, such as but not limited to polyalkylene polyols and polyoxyalkylene polyols.

A nonlimiting embodiment of the resin compatible coating compositions can additionally include one or more emulsifying agents for emulsifying or dispersing components of the coating compositions, such as the particles and/or lubricious materials. Nonlimiting examples of suitable emulsifying agents or surfactants include polyoxyalkylene block copolymers, ethoxylated alkyl phenols, polyoxyethylene octylphenyl glycol ethers, ethylene oxide derivatives of sorbitol esters, polyoxymethylated vegetable oils, ethoxylated alkylphenols, and nonylphenol surfactants.

Other additives can be included in a nonlimiting embodiment of the resin compatible coating compositions, such as crosslinking materials, plasticizers, silicones, fungicides, bactericides and anti-foaming materials. Organic and/or inorganic acids or bases in an amount sufficient to provide
the coating composition with a pH of 2 to 10 can also be included in the resin compatible coating composition.

Nonlimiting examples of resin compatible coatings are shown in Table 1.

Additional nonlimiting examples of glass fiber yarns having a resin compatible coating are disclosed in U.S. Ser. No. 09/620,526 entitled ‘Impregnating Glass Fiber Strands and Products Including the Same’ and filed Jul. 20, 2000, which is hereby incorporated by reference.

Although the whip roll as disclosed herein is particularly useful when weaving glass fiber yarns having a resin compatible coating, the whip roll is especially effective when weaving fine yarns having a resin compatible coating. As used herein, the term “fine yarn” means yarns having a filament diameter of no greater than about 2.9x10<sup>-4</sup> inches (about 7.4 micrometers), and include but are not limited to E225, D450 and D900 yarns. For example, a non-limiting fabric style using E225 E-glass fiber yarns is Style 2116, which has 118 warp yarns and 114 fill (or weft) yarns per 5 centimeters (60 warp yarns and 58 fill yarns per inch); uses 7.22 1x0 (E225 1 0/0 warp and fill yarns; has a nominal fabric thickness of 0.094 millimeters (about 0.037 inches); and a fabric weight (or basis weight) of 103.8 grams per square meter (about 3.06 ounces per square yard). A non-limiting example of a fabric style using D450 E-glass fiber yarns is Style 1080, which has 118 warp yarns and 93 fill yarns per 5 centimeters (60 warp yarns and 47 fill yarns per inch); uses 5.11 1x0 (D450 1 0/0 warp and fill yarns; has a nominal fabric thickness of 0.053 millimeters (about 0.0021 inches); and a fabric weight of 46.8 grams per square meter (about 1.38 ounces per square yard). A non-limiting example of a fabric style using D900 E-glass fiber yarns is Style 106, which has 110 warp yarns and 110 fill yarns per 5 centimeters (56 warp yarns and 56 fill yarns per inch); uses 5.5 1x1 (D900 1 0/0 warp and fill yarns; has a nominal fabric thickness of 0.033 millimeters (about 0.013 inches); and a fabric weight of 24.4 grams per square meter (about 0.72 ounces per square yard). Another non-limiting example of a fabric style using D900 E-glass fiber yarns is Style 108, which has 118 warp yarns and 93 fill yarns per 5 centimeters (60 warp yarns and 47 fill yarns per inch); uses 5.5 1x1 (D900 1 0/0 warp and fill yarns; has a nominal fabric thickness of 0.061 millimeters (about 0.0024 inches); and a fabric weight of 47.3 grams per square meter (about 1.40 ounces 25 per square yard). A non-limiting example of a fabric style using both E225 and D450 E-glass fiber yarns is Style 2113, which has 118 warp yarns and 110 fill yarns per 5 centimeters (60 warp yarns and 56 fill yarns per inch); uses 7.22 1x0 (E225 1 0/0 warp yarn and 53.11 1x0 (D450 1 0/0 fill yarn; has a nominal fabric thickness of 0.079 millimeters (about 0.0031 inches); and a fabric weight of 78.0 grams per square meter (about 2.30 ounces per square yard).

These and other fabric style specification are given in IPC-EG-140 “Specification for Finished Fabric Woven from ‘E’ Glass for Printed Boards”, a publication of The Institute for Interconnecting and Packaging Electronic Circuits (June 1997), which is specifically incorporated by reference.
Although the aforementioned fabric styles use twisted yarns, it is contemplated that these or other fabric styles using zero-twist yarns or rovings in conjunction with or in lieu of twisted yarns can be made in accordance with the present invention.

It is noted that the above fabric types each include at least 56 warp yarns per inch while a fabric such as a 7628 style fabric which uses a coarser G75 yarn includes 44 yarns per inch. It is believed that the increased yarn density of fabrics incorporating the fine warp yarns contributes to the tendency of the fine yarn to become entangled on a standard whip roll. As a result, in one non-limiting embodiment of the present invention, the whip roll is used to weave fabrics incorporating warp yarn having a resin compatible coating and a warp yarn density of at least 50 warp yarns per inch, preferably at least 56 warp yarns per inch, and more preferably at least 60 warp yarns per inch.

It will be appreciated by those skilled in the art that changes could be made to the embodiments described above without departing from the broad inventive concept thereof. It is understood, therefore, that this invention is not limited to the particular embodiments disclosed, but is intended to cover modifications which are within the spirit and scope of the invention, as defined by the appended claims.

I claim:

1. A method of delivering warp yarn into an air jet loom, comprising the steps of:
   - providing a loom beam comprising warp yarn having a resin compatible coating;
   - drawing warp yarn from the loom beam;
   - contacting the warp yarn with a whip roll having a reduced surface area such that the warp yarn contacts at least a portion of the reduced surface area of the whip roll; and
   - directing the warp yarn into an air jet loom.

2. The method according to claim 1, wherein at least a portion of the reduced surface area of the whip roll has a textured surface.

3. The method according to claim 1, wherein the providing step provides the warp yarn at a warp yarn density of at least 50 yarns per inch.

4. The method according to claim 3, wherein the providing step provides the warp yarn at a warp yarn density of at least 56 yarns per inch.

5. The method according to claim 4, wherein the providing step provides the warp yarn at a warp yarn density of at least 60 yarns per inch.

6. The method according to claim 1 wherein the providing step comprises providing a warp yarn that is a fine yarn.

7. The method according to claim 1, wherein the roll includes a plurality of grooves extending along at least a portion of the roll.

8. The method according to claim 1, further including the step of forming a warp shed from the warp yarn and inserting a fill yarn having a resin compatible coating into the warp shed.

9. The method according to claim 1, wherein the reduced surface area of the whip roll includes a plurality of grooves.

10. The method according to claim 9 wherein the grooves are equally spaced and generally parallel to each other.

11. The method according to claim 1, wherein the reduced surface area of the whip roll is no greater than 50% of its equivalent surface.

12. The method according to claim 11, wherein the reduced surface area of the whip roll is no greater than 25% of its equivalent surface.

13. The method according to claim 11, wherein the providing step provides the warp yarn at a warp yarn density of at least 50 yarns per inch.

14. The method according to claim 13, wherein the reduced surface area of the whip roll includes a plurality of grooves.

15. The method according to claim 14 wherein the providing step comprises providing a warp yarn that is a fine yarn.

16. The method according to claim 15, wherein at least a portion of the reduced surface area of the whip roll has a textured surface.

17. The method according to claim 1, further including the step of forming a warp shed from the warp yarn and inserting a fill yarn having a resin compatible coating into the warp shed.

18. A fabric made according to the method of claim 1.

19. A fabric made according to the method of claim 17.
