Abstract

Disclosed is a method for producing colloidal graphene dispersions comprising the steps of

5 (i) dispersing graphite oxide in a dispersion medium to form a colloidal graphene oxide or multi-graphene oxide dispersion

(ii) thermally reducing the graphene oxide or multi-graphene oxide in dispersion.

10 Dependent on the method used for the preparation of the starting dispersion a graphene or a multi-graphene dispersion is obtained that can be further processed to multi-graphene with larger inter-planar distances than graphite. Such dispersions and multi-graphenes are for example suitable materials in the manufacturing of rechargeable lithium ion batteries.

Invention Title: **Stable dispersions of a single and multipul graphene layers in solution**

The following statement is a full description of this invention, including the best method of performing it known to us:

2010202051 20 May 2010

Stable dispersions of single and multiple graphene layers in solutionTechnical Field

The present invention concerns the field of electronically conductive
5 carbonaceous materials and their production, in particular materials suitable
for use in rechargeable lithium ion batteries.

Background Art

The term graphene designates a one atom thick planar sheet of sp^2 -
10 hybridized rings with 6 carbon atoms. Perfect graphenes consist exclusively
of hexagonal cells. Cylindrical graphene layers are termed carbon
nanotubes. The term graphene may also be used when features of single
layers in graphite are discussed. Such features are e.g. reactivity or
undergone reactions, respectively, or structural relations.

15 Graphene layers may be produced by suitable abrasion, mechanical
exfoliation or chemical vapour deposition. One such method is the so called
Scotch-Tape-Method [10]. In this method single layers are removed from a
graphite crystal and transferred to a sample holder.

In a recently described chemical vapour deposition method is
20 disclosed, wherein, prior to being able to generate a graphene layer, a
 SiO_2/Si substrate has to be covered with a thin Ni layer, and this coated
substrate has to be subjected to a specific gas treatment. For making the
graphene layer usable to coat other substrates, the Ni or the SiO_2 layer
have to be dissolved. Such graphene films had very good electrical, optical
25 and mechanical (e.g. bending) properties [9].

Another method is to heat silicon carbide to high temperatures
(1100°C) to reduce it to graphene. This process produces a layer the extent
of which is dependent on the size of the SiC substrate used and - due to the

expensive starting material - is quite expensive and also limited in use due to the high temperature needed.

Graphene is quite different from most solids. Graphene behaves as a semi-metal or "zero-gap" semiconductor and has a remarkably high electron mobility at room temperature.

Aqueous dispersions of carbonaceous material such as graphite, graphene or carbon nanotubes are described in literature. The production of aqueous graphite dispersions from graphite with preferred particle sizes between 1 μm and 50 μm or 100 μm , respectively, stabilized by various dispersants has been described (see e.g. US 5,476,580 and WO2007/031055). Up to 20 % by weight or up to 70 % by weight, respectively, graphite may be dispersed in water.

Dispersions of carbon nanotubes with a nanotubes content of 2 % are e.g. obtainable by stabilization with the dispersing aid polyethylene glycol [1] or via chemical functionalizing of the carbon nanotubes [2].

WO2008/048295 describes a method for stabilizing graphene layers in a solvent by means of polymer coating. An about 0.065 % by weight graphene based material is obtained. The colloidal graphene dispersion is provided by reduction of dispersed graphite oxide using hydrazine hydrate.

Dan Li et al. [3] describe that the aqueous solution may be electrostatically stabilized by ammonia resulting in a graphene based material with graphene content of about 0.015 % by weight. Also Dan Li et al. prepared the colloidal graphene dispersion from a graphite oxide dispersion by reduction with hydrazine hydrate. The reduction with hydrazine hydrate as disclosed in the state of the art results in a C/O ratio of below 13.5 meaning that at most about 80 % of the oxygen have been removed [4, 5, 6].

Another method for reduction of graphite oxide is thermal reduction. Dependent on the desired production conditions, purity conditions and reduction conditions, the thermal reduction of graphite oxide powder is slow up to a temperature of about 200°C and then becomes boisterous [7].

Reduction at this temperature results in an elimination of about 65 % of the oxygen, 10 % of the carbon and most of the hydrogen due to the formation of CO, CO₂ and water. Heating to higher temperatures results in continuous further reduction. A temperature of about 1000°C is required for removal of
5 about 90 % of the oxygen. Thus produced graphite material can no longer be dispersed in water to form a colloidal dispersion.

Disclosure of the Invention

Hence, it is a general object of the invention to provide a method for
10 producing stable colloidal dispersions of graphene in solution, in particular colloidal graphene dispersions that do not need any dispersant.

It is also an object of the present invention to provide stable dispersions of single and multiple graphene layers.

It is also an object of this invention to provide uses of such graphene
15 dispersions.

It is a further object of the invention to provide a multi-graphene with improved intercalating features that may e.g. advantageously be used for the production of electrodes in rechargeable lithium ion batteries.

Now, in order to implement these and still further objects of the
20 invention, which will become more readily apparent as the description proceeds, the method for producing colloidal graphene dispersions is manifested by the features that it comprises the steps of

- (i) dispersing graphite oxide in a dispersion medium to form a colloidal graphene oxide or graphite oxide dispersion,
- 25 (ii) thermally reducing the graphene oxide or graphite oxide in dispersion.

In the scope of the present invention the dispersion related terms are used with the following meanings:

Dispersion is a two phase system consisting of a disperse phase in a dispersion medium, wherein the disperse phase is finely divided in the dispersion medium.

Disperse phase designates the solid, optionally colloidal phase.

5 *Dispersion medium* is used as synonym to continuous phase and liquid phase. Since the dispersion medium is a substance or a mixture of substances known as solvents, also the term solvent or solvent phase is used. The dispersion medium may also comprise additives and adjuvants such as dispersants.

10 *Dispersants* are substances that assist in stabilizing dispersions, that e.g. prevent coagulation and/or aggregation of the dispersed phase, such as surfactants. In this text, dispersants are also termed dispersing agents, dispersing aids.

15 In the scope of the present invention, the terms describing the carbonaceous material are used as follows:

If not further specified, the term *graphene* alone or in graphene oxide designates a single layer of graphite or graphite oxide, respectively.

An assembly of two or more graphene layers with the usual interplanar distance of graphite are termed graphite.

20 An assembly of two or more graphene layers with a larger interplanar distance than in graphite are termed *multi-graphene*.

For graphite oxide the same distinction is made, in particular with regard to the product finally obtained therefrom.

25 The terms graphene/multi-graphene/graphite are used for carbonaceous materials with carbon : oxygen (C/O) ratio of ≥ 4 , the terms graphene oxide/multi-graphene oxide/graphite oxide for materials with C/O ratio < 4

Reducing the graphene oxide in dispersion means that during the reduction step the graphene oxide/graphene or graphite oxide/graphite

2010202051 20 May 2010

remains dispersed in solvent. For low boiling solvents, this can be achieved by heating the dispersion under pressure, e.g. in an autoclave, preferably an autoclave with a polytetrafluoroethylen (Teflon®) insert or a glass autoclave.

Dependent on the desired carbon : oxygen (C/O) ratio, the thermal
5 reduction step is performed at low temperatures of about 120 to 130°C or at higher temperatures of at least about 130°C. Temperatures around 120°C allow fine-tuning of the desired C/O ratio but they cannot be used for reduction up to high C/O ratios or only at very long reaction times. The higher the reaction temperature, the faster the reduction proceeds. This
10 allows the fast production of high C/O ratios.

For example, by the inventive method, already at 140°C about 80 % of the oxygen are removed and thus already at this temperature a C/O ratio of above 13.5 is obtained, i.e. a C/O ratio better than reported for reduction with hydrazine hydrate. Already at 250°C (compared with the 1000°C
15 reported in the literature) more than 90 % of the oxygen is removed while the colloidal dispersion of the single graphene layers is still longtime stable.

Longtime stable in the context of the present invention means that the graphene remains colloidally dispersed for at least 1 day, preferably for at least 1 week, more preferred for at least 1 month or 3 months, most
20 preferred for at least 1 year (measured at room temperature for a 0.1 % by weight dispersion).

Colloidal graphene dispersions of the present invention are preferably produced with a graphene content of at most 0.5 % by weight, usually about 0.1 % by weight or – dependent on the application - more diluted. Such
25 stable dispersions may be obtained up to C/O ratios of more than 25.

A C/O ratio of 26 for example means that about 90 % of the oxygen has been removed which proved to be a very good graphite/graphene purity for several applications. For many applications, however, poorer C/O ratios are already usable or even preferred. Such poorer C/O ratios are e.g. a C/O
30 ratio of at least 4, but preferably at most 13, such as a C/O ratio of about 7.

For other applications, where high C/O ratios are preferred such C/O ratio is at least 13.5, preferably at least 20, more preferred at least 25.

5 In one embodiment of the invention, the dispersion is an aqueous dispersion. Such aqueous dispersion can be produced in a wide pH range of 4.5 to 14 without need for a dispersant although dispersants or other adjuvants and/or additives may be added to further improve the features of the dispersion or a layer formed thereof by graphene deposition.

10 Surprisingly, the inventors found that the parameters of the inventive method can be varied in a broad range without affecting the quality of the colloidal graphene dispersion.

A colloidal graphene oxide dispersion suitable as starting material can be prepared by stirring graphite oxide powder in the desired solvent, e.g. water, until the colloidal dispersion appears clear to the eye. If no clear dispersion is obtained after 1 to 5 hours, the dispersion may be centrifuged
15 to remove undissolved impurities. The time needed may be shortened by the addition of minimal amounts of ammonia. Such amounts usually are below a level that would alter the pH obtained in the absence of ammonia.

20 It is also possible to accelerate dissolution by using ultrasonic treatment. However, such treatment reduces the size of the graphene oxide layers and therewith of the graphene layers.

The dispersion is then heated. A temperature of at least about 150°C is presently assumed to be necessary for efficient reduction, in particular for aqueous dispersions. More than 300°C may further improve the C/O ratio, however this is unnecessary for hitherto envisaged applications.

25 The heating speed is uncritical. A reaction time at the desired temperature of less than 5 hours has been found to be sufficient. Usually already about 1 hour at the desired temperature is sufficient for aqueous dispersions. In the case of other solvents adaptation of the parameters such as temperature and time may be advantageous.

2010202051 20 May 2010

Suitably the high temperature reactions with low boiling solvents such as water are performed in an autoclave. Neither higher pressure than the pressure generated by the solvent is needed nor a specific, e.g. inert, atmosphere.

5 Solvents other than water that may be used are polar protic but also polar aprotic solvents such as acetonitrile or formamide.

Also apolar solvents are suitable continuous phases for colloidal graphene dispersions. However, while the graphite oxide powder is readily dispersible in polar solvents, it is hardly or not wettable in apolar solvents.
10 Thus, for producing a colloidal graphene dispersion in apolar solvents, the graphite oxide is dispersed in a polar solvent and then mixed with an apolar solvent, wherein the mixture of said polar and said apolar solvent has to be miscible at high temperatures although not at room temperature. Such mixture is then subjected to high temperature in an autoclave until the
15 reduction to graphene took place. Then the polar solvent is removed, e.g. by decanting the upper phase or releasing the lower phase from a separation funnel. Solvent systems suitable for this method are known to the skilled person as TMS systems (Temperature Depending Multicomponent Solvent System).

20 The high thermal conductivity, the unusual electrical features and the high mechanical stability of graphene that is similar to or even better than the one of carbon nanotubes make graphene a much promising component of composite materials.

The colloidal graphene dispersions of the present invention may be
25 used for coating substrates such as nanoparticles that may be used as electrode materials in rechargeable lithium batteries.

If for chemical and/or technical reasons it is impossible to produce a graphene/graphite comprising composit starting from the inventive colloidal graphene dispersion, then a graphite oxide or graphene oxide comprising
30 composite material may be produced and this material may then be reduced with the thermal reduction method of the present invention.

2010202051 20 May 2010

It has also been found that graphite oxide powder can directly be subjected to heat in a not drying environment, e.g. as indicated above in an autoclave, resulting in a multi-graphene, i.e. a carbonaceous material with larger interspace between two crystal lattice planes, i.e. between two
5 graphene layers, and therefore with improved intercalating properties compared to graphite. Without wanting to be bound by any theory, it is assumed that the water present between the graphene oxide layers prevents the formation of "usual" graphite upon thermal reduction under not drying conditions.

10 Such multi-graphenes in dispersed or isolated form may either be produced directly or via precipitation from colloidal graphene dispersions, and they have an inter-planar distance of greater than 3.35 Å, preferably greater than 3.40 Å, or greater than 3.50 Å, or greater than 3.60 Å, e.g. 3.55 Å or 3.68 Å.

15 Under milder reaction conditions than used for graphene/multi-graphene production with high C/O ratio, e.g. 140°C for 5 hours in an autoclave, a graphite based material may be obtained having a much larger inter-planar distance, e.g. of about 4.6 Å. Such a material, although having a "poor" C/O ratio was found to nevertheless have sufficient conductivity to be
20 used as electrode material. Dependent on the C/O ratio, the material may be loaded with Li⁺ ions and used as cathode material (graphite oxide like carbonaceous material) or it can be used as anode material with the ability to take up Li⁺ ions in the inter-planar space. For example graphite oxide with the chemical formula C₈O₄H₂ may be treated with LiOH to give (in case of
25 optimal exchange) C₈O₄Li₂.

Electrodes may be produced by coating a conductor such as an aluminum foil with the carbonaceous materials of the present invention.

A further benefit of the present invention is that the reduction of graphite oxide or graphene oxide composite materials or coatings may be
30 performed in the presence of materials that treated with the methods of the

2010202051 20 May 2010

state of the art would be destroyed, either by the chemical reaction or by the high temperature.

Brief Description of the Drawings

5 The invention will be better understood and objects other than those set forth above will become apparent when consideration is given to the following detailed description thereof. Such description makes reference to the annexed drawings, wherein:

10 Figure 1 is a cryo-transmission electron microscope image of a graphene dispersion

Figure 2 is the powder diffractogram of multi-graphene precipitated from colloidal graphene dispersion showing reflexes similar to those of turbostratic graphite but with inter-planar distances of 3.55 Å.

15 Figure 3 is a powder diffractogram of a multi-graphene showing that the reflexes are similar to those of turbostratic graphite but with inter-planar distances of 3.68 Å.

20 Figure 4 shows an X-ray diffraction diagram in Brag-Brentano geometry indicating that during the coating with graphene oxide, the graphene oxide platelets during drying were deposited in a horizontal manner and formed the graphite oxide layer wise.

Figure 5 shows a gold-(multi-)graphene composite that has been obtained from colloidal dispersed gold and the inventive colloidal graphene dispersion by co-precipitation.

25 Modes for Carrying Out the Invention

Colloidal graphene dispersions can be readily produced by thermal reduction of colloidal graphene oxide dispersions.

The production method for the graphene oxide powder starting material is not critical. A suitable improved Brodie method has been

described by Boehm et al. [8]. Starting from powdered graphite oxide, first a dispersion in the desired solvent or solvent system is produced.

Such colloidal graphene oxide dispersion can be readily obtained by stirring graphite oxide powder in a graphite oxide wetting (dispersing) solvent or solvent mixture or solvent system. The time needed for producing the colloidal graphene oxide dispersion can vary dependent on the solvent chosen, however the time needed can easily be determined visually, i.e. as soon as a clear "solution" (colloidal dispersion) is obtained, stirring can be ended and thermal reduction can be started. If the solution remains turbid after about 5 hours or if no reduction in turbidity can be observed for some time, impurities may be present that should be removed prior to starting thermal reduction, e.g. via centrifugation or a filtration step.

Ultrasonic treatment was found to speed up the "dissolution", however it also reduced the size of the graphene oxide and hence the size of the graphene layers. An alternative to ultrasonic treatment is the addition of very small amounts of ammonia.

If the solvent has a boiling point below or close to the desired reaction temperature, the thermal reduction is preferably performed in an autoclave to ensure that the solvent is not evaporated during the reduction step.

In spite of a high C/O ratio, the colloidal graphene dispersions of the present invention exhibit good stability. Such high C/O ratio is obtained at temperatures of about 150°C and is already excellent at about 250°C for aqueous dispersions. Treatment at more than 300°C might lead to even improved dispersions, however, for most applications this is unnecessary. In addition, if deposition of graphene layers on substrates is desired during the reduction step, low temperatures are much favored for temperature sensitive substrates.

If for chemical and/or technical reasons it is impossible to produce a graphene/multi-graphene comprising composite starting from the inventive colloidal graphene dispersion, then a multi-graphene oxide or graphene

oxide comprising composite material may be produced and this material may then be reduced with the thermal reduction method of the present invention.

The invention is now further described by means of some examples.

5 In these examples an autoclave with a polytetrafluoroethylen (Teflon®) insert was used.

Example 1: Preparation of graphite oxide

Graphite oxide was prepared according to the well known method by
10 Brodie as modified by Boehm et al. [8].

10 g graphite were thoroughly mixed with 85 g sodium perchlorate powder. The mixture was cooled to approx. -20°C using an ice sodium chloride mixture and then slowly stirred with an efficient stirrer. Then 60 ml fuming nitric acid were very slowly added. The viscous green mass was
15 stirred for an additional 30 minutes at room temperature. The mixture was left over night without agitation and then slowly heated to 60°C for 10 hours. Then 2 liters of water were added to the reaction product, the mixture was filtered and once washed with diluted hydrochloric acid and at least twice, each time with 2 liters of water. After filtration, the obtained mass was freeze
20 dried yielding about 14 g of graphite oxide as a very fluffy ivory colored powder.

Based on the elemental analysis of the graphite oxide the chemical formula $C_8O_4H_{1.7}$ results. After subtraction of hydrogen as water the formula $C_8O_{3.2}$ is obtained with a C/O ratio of 2.5. Using X-ray diffraction analysis it
25 could be shown that the inter-planar distance of 3.35 Å in graphite was enlarged to 6.1 Å in dry graphite oxide.

Example 2: Preparation of a colloidal graphene oxide dispersion

100 mg of the graphite oxide obtained as described in Example 1
30 were added to 100 ml of deionized water, thoroughly stirred for 12 hours

and then left in an ultrasonic bath for 1 hour. The such obtained colloidal dispersion of graphite oxide (further on referred to as graphene oxide), was then reacted to colloidal graphene dispersion (see below).

5 The colloidal graphene oxide dispersion obtained by dispersing graphite oxide in water was optically clear to the naked eye and even in the light microscope at 1000 fold magnification, free of particles and had a pH of about 5. Using a laser, the resulting Tyndall effect showed that the graphite oxide resulted in a colloidal dispersion.

10 If such dispersion is diluted and then applied to a suitable sample holder, scanning force microscopy reveals that the colloidal dispersion consists of single layers of oxidized graphene, i.e. graphene oxide.

Example 3: Preparation of a coarse multi-graphene oxide dispersion

15 1 g of the graphite oxide obtained as described in Example 1 were added to 100 ml of deionized water acidified with hydrochloric acid to a pH of about 4. After stirring for 1 hour, the obtained coarse dispersion of multi-graphene oxide, was suitable for further reaction to a dispersion of multi-graphene (see below).

20 Example 4: Preparation of colloidal graphene dispersion and multi-graphene

The colloidal graphene oxide dispersion of Example 2 was placed in an autoclave and heated at a temperature of 170°C for 5 hours. During this treatment the single layers of the graphene oxide were reduced to graphene
25 resulting in a colloidal dispersion of graphene in water.

The resulting colloidal graphene dispersion was deeply black and had a pH of about 5. To the naked eye and even in the light microscope at 1000 fold magnification, the dispersion was free of visible particles and - as the colloidal graphene oxide dispersion - showed the Tyndall effect of a colloidal
30 dispersion.

2010202051 20 May 2010

Using image giving methods such as scanning force microscopy and transmission electron microscopy it could be shown to be a colloidal dispersion. The single layers are e.g. clearly recognizable in a cryo-transmission electron microscope image (Figure 1).

5 The lateral diameter of the graphene layers was in the range of the lateral diameter of the starting material and thus was dependent of the diameter of the single graphene layers in the graphite prior to its oxidation to graphite oxide. By evaporation of the water from the dispersion the graphene could be precipitated as multi-graphene. Residual water was
10 removed by drying in vacuum and the product was subjected to different tests.

The powder diffractogram (Figure 2) showed reflexes similar to those of turbostratic graphite with inter-planar distances of 3.55 Å.

Elemental analysis of the material gave the chemical formula
15 $C_8O_{0.65}H_{0.5}$. After subtraction of hydrogen as water the formula was $C_8O_{0.4}$ resulting in a C/O ratio of 20. Thus, 88 % of the oxygen have been removed from the graphene oxide. X-ray diffraction and elemental analysis clearly characterized the material as multi-graphene and thus the colloid as single graphene layers in pure water that is longtime stable without additives, at
20 present for more than one year.

Example 5: Preparation of multi-graphene

The dispersion of multi-graphene oxide of Example 3 was placed in an autoclave and heated for 5 hours at a temperature of 200°C. By this
25 procedure, the multi-graphene oxide was reduced to multi-graphene. The suspension was then filtered and the obtained multi-graphene was dried.

Due to the pH of about 4 in the dispersion medium, the graphite oxide was not divided into its single layers but merely to an enlarged inter-planar distance of up to about 11 Å (a multi-graphene oxide).

2010202051 20 May 2010

If graphite oxide powder is reduced according to thermal treatment methods of the state of the art, up to about 200°C water is removed and the inter-planar distance diminishes to about 4.4 Å while about 65 % of the oxygen are removed from the graphite oxide. Temperature increase up to 1000°C leads to further diminishing of the inter-planar distance to 3.38 Å while about 90 % of the oxygen are removed.

If the thermal reduction of a dispersion of multi-graphene oxide was performed in the autoclave according to the present invention at a temperature of about 200°C, the inventive kind of reduction lead to a reduction of the oxygen content of about 90 % (similar to a state of the art treatment at 1000°C) but the inter-planar distance remained at 3.68 Å instead of the formerly found 3.38 Å. For the inventive treatment at 200°C and more, the inventors assumed that under the thereby generated conditions, such as high pressure, the water between the layers of the multi-graphene oxide/multi-graphene cannot leave or only with difficulties, resulting in a larger inter-planar distance.

In a recently published article from Nethravathi and Rajamathi, they reported a black precipitate of aggregated graphite layers [11]. In contrast to this finding, the inventive method resulted in a stable aqueous dispersion wherein the graphene layers were not fully separated but more distant from each other than in graphite.

The different result achieved by the present inventors is assumed to be due to the fact that they ensured that all graphite oxide or graphene oxide, respectively, is colloidally dispersed, i.e. that no larger particles remain that might act as nuclei for graphene precipitation. Although Nethravathi and Rajamathi state to have started from a colloidal dispersion, the fact that they used several solvents that are unsuitable to colloidally disperse the graphite oxide, the conclusion that may be deduced thereof is that also the aqueous dispersions were not treated sufficiently long to ensure the total removal of all precipitation and agglomeration favoring particles.

2010202051 20 May 2010

From the elemental analysis of the material the chemical formula $C_8O_{0.5}H_{0.3}$ was deduced and - corrected for remaining water - the formula $C_8O_{0.35}$. The C/O ratio was above 22. The powder diffractogram in Figure 3 shows reflexes that are similar to those of turbostratic graphite but with inter-planar distances of 3.68 Å. X-ray diffraction and elemental analysis unambiguously characterize this multi-graphene material as closely related to turbostratic graphite.

Under milder reaction conditions, e.g. 140°C for 5 hours in an autoclave, a graphite based (multi-graphene) material was obtained having a large inter-planar distance of about 4.6 Å. This material had a poor C/O ratio but was nevertheless found to have sufficient conductivity to be used as electrode material.

Example 6: Preparation of graphene coatings through thermal reduction of graphene oxide coatings

If for chemical and/or technical reasons it is impossible to produce a graphene/graphite comprising composite starting from the inventive colloidal graphene dispersion, then a multi-graphene oxide or graphene oxide comprising composite material may be produced and this material may then be reduced with the thermal reduction method of the present invention.

For example a colloidal graphene oxide dispersion was produced as described in Example 2 above. This colloidal dispersion was then applied to a quartz plate as a thin layer. The quartz plate was then immersed into acidic water of pH about 4 (acidified with hydrochloric acid) and the dispersion was then treated in an autoclave at 200°C for 5 hours to reduce the graphene oxide layers and to consequently coat the quartz plate with graphene or multi-graphene.

During the coating with graphene oxide, the graphene oxide platelets were deposited during drying in a horizontal manner and formed the multi-graphene oxide layer wise. This could be shown with X-ray diffraction in Bragg-Brentano geometry (see Figure 4). Only the 001 reflection resulting

from reflection at the single graphene oxide layers could be seen. The inter-planar distance was 6.4 Å. The 100 and 110 reflections cannot be seen as it is the case with powder samples. After reduction, the layered structure was also found in the so obtained multi-graphene. In the diffractogram again only
5 the 002 reflection of the graphite could be seen. The inter-plane distance was 3.65 Å.

The elemental analysis of the material gave the chemical formula $C_8O_{0.5}H_{0.3}$, after subtraction of hydrogen as water $C_8O_{0.3}$, and therewith a C/O ratio of above 22.

10 The X-ray diffraction and the elemental analysis clearly characterized the material as multi-graphene.

Example 7: Preparation of a gold-graphene/multi-graphene composit

A composite material has been obtained from colloiddally dispersed
15 gold and the colloidal graphene dispersion of Example 4 by co-precipitation. Co-precipitation was induced by adding a very small amount of an electrolyte such as sodium chloride. Figure 5 shows such a gold-(multi-) graphene composit.

20 Possible uses for the colloidal graphene dispersions of the present invention:

Graphene single and double layers show semi-metallic features with good electrical conductivity that is almost temperature independent. Single graphene layers are interesting for fundamental electronic investigations
25 and novel nano-electronic applications. For example the Quantum-Hall Effect at room temperature and further magneto-electrical as well as optical features may be observed [10]. Due to these features a lot of research was started on graphene by primarily practically as well as primarily theoretically interested people. Hitherto only few methods for the preparation of single
30 graphene layers and their deposition on suitable carriers exist. Therefore

the investigations that may be performed are limited. The known methods are very time consuming and have little outcome of suitable samples.

Contrary thereto, the inventive method allows the production of large quantities of graphene layers dispersed in pure water or other solvent (see above). No additives or reducing agents are needed. The C/O ratio can reach values above 25. From such a pure colloidal dispersion the single graphene layers can purposefully be deposited, e.g. between two electrodes via dielectrophoresis and subjected to specific investigations what is hardly - if at all - possible by means of e.g. the Scotch-Tape-Method.

By suitable methods layers and coatings can be produced from the colloidal graphene dispersion. Dependent on the method these can be few nanometers thin, i.e. single layers, they may be transparent and they may for example be used as replacement for indium tin oxide in organic light-emitting diodes, graphene transistors, or as thin-film solar cells. But also thicker layers may be produced such as macroscopic layers. Such macroscopic layers are e.g. multi-graphene foils and membranes that find application e.g. in electrical engineering and in desalinization. It is possible to prepare layers or coatings such that an orientation and therewith an anisotropic material results. This is also a very good and simple alternative method to the production of highly oriented pyrolytic graphite (HOPG).

The high thermal conductivity, the unusual electronic features and the high mechanical and chemical stability of graphene that exceeds those of carbon nanotubes, make graphene a much promising material for composite materials.

From colloidal graphene dispersions in various solvents composite materials with very homogeneous distribution of the materials can readily be produced. The advantage of a composite material from a colloidal graphene dispersion is especially high if the further materials of the composite (besides of the graphene) can also be applied in colloidally dispersed or at least in nanodispersed form. For example a tin-(multi-)graphene composit or a silicon-(multi-)graphene composit are much promising materials for

respective batteries, in particular if tin and silicon are also finely divided in the solvent. In Figure 5 a gold-(multi-)graphene composite is shown that has been obtained from colloiddally dispersed gold and the colloidal graphene dispersion by co-precipitation (see Example 7).

5 Another mode of application is the coating of a template of any shape with the colloidal graphene dispersion of the present invention. As many coatings as desired may be applied to the surface of the template and then the graphene/multi-graphene precipitated therefrom by e.g. evaporation of the solvent. As soon as the multi-graphene layer has the desired thickness,
10 the template may also be removed leaving a shaped carbon product with any desired form and wall thickness, wherein the arrangement of the graphene layers may be anisotropic.

An envisaged new application is the production of conducting glasses wherein the colloidal graphene dispersion is used as additive in the scope of
15 a sol-gel-process performed by adding the dispersion to the sol or gel (e.g. water-glass).

Possible uses for the multi-graphene product of the present invention:

Under suitable reaction conditions, e.g. 140°C for 5 hours in an
20 autoclave, a carbonaceous material (multi-graphene) is obtained having a large inter-planar distance of about 4.6 Å and with sufficient conductivity to be used as electrode material . Carbonaceous materials with large interplanar distances have many advantages as electrode materials in rechargeable batteries such as easy intercalation/deintercalation of ions
25 into/from the carbon compound.

Possible uses for the multi-graphene layers of the present invention:

The multi-graphene layers/coatings that may e.g. be produced according to Example 6 have applications as membranes, anisotropic
30 conductors and super condensers.

2010202051 20 May 2010

Possible further uses of products of the present invention:

Due to the possibility to produce carbonaceous materials with almost every C/O ratio, and on almost every substrate, such materials are also very
5 suitable to produce condensers. For such applications, several (e.g. about 40) layers are deposited on a plastics foil such as a polyethylene or polycarbonate foil. The easy variability of the C/O ratio also favors the use of the inventive carbonaceous materials as electrode material in rechargeable lithium ion batteries.

10 Such electrodes for rechargeable lithium ion batteries may be prepared by a method comprising the step of providing a multi-graphene and coating a conductor with said multi-graphene, optionally in the presence of a binder.

15 While there are shown and described presently preferred embodiments of the invention, it is to be distinctly understood that the invention is not limited thereto but may be otherwise variously embodied and practiced within the scope of the following claims.

15

THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:

1. A method for producing colloidal graphene dispersions or multi-graphene dispersions comprising the steps of
 - 5 (i) dispersing graphite oxide in a dispersion medium to form a colloidal graphene oxide dispersion or a multi-graphene oxide dispersion
 - (ii) thermally reducing the graphene oxide or multi-graphene oxide in dispersion.
2. The method of claim 1 wherein step (ii) is performed at a
10 temperature of at least 120°C.
3. The method of claim 1 wherein step (ii) is performed at a temperature of 120°C to 130°C.
4. The method of claim 1 wherein step (ii) is performed at a temperature of at least 130°C.
- 15 5. The method of claim 1 wherein step (ii) is performed at a temperature of at least 150°C.
6. The method of claim 1, wherein the dispersion medium is a protic, polar dispersion medium, preferably a water based dispersion medium.
- 20 7. The method of claim 6, wherein the dispersion medium is water, the dispersion in step (i) is a colloidal graphene oxide dispersion and the dispersion produced in step (ii) is a colloidal graphene dispersion.
8. The method of claim 6, wherein the dispersion medium comprises ammonia.
- 25 9. The method of claim 1, wherein the dispersion medium is an aprotic, polar dispersion medium, preferably acetonitrile.
10. The method of claim 1, wherein step (ii) is performed at a temperature and for a time to result in a colloidal graphene dispersion with a carbon : oxygen (C/O) ratio of at least 4 and preferably at most 13, such as

about 7, most preferred or at least 13.5, preferably at least 20, more preferred at least 25.

11. The method of claim 6, wherein the dispersion medium is acidified water, preferably water of a pH of about 4, the dispersion in step (i) is a multi-graphene oxide dispersion and the dispersion produced in step (ii) is a multi-graphene dispersion.

12. A method for producing a graphene or multi-graphene layer or multi-graphene particles using the method of anyone of the preceding claims comprising the steps of

10 (i) dispersing graphite oxide in a dispersion medium to form a graphene oxide or multi-graphene oxide dispersion

(ii) thermally reducing the graphene oxide or multi-graphene oxide in dispersion, and either

15 deposit on a substrate or precipitate the dispersion of step (i) and then perform step (ii) or

deposit on a substrate or precipitate the dispersion of step (ii).

13. A colloidal graphene dispersion, preferably obtainable by the method of any one of the preceding claims, with a C/O ratio of at least 4 and preferably at most 13, such as about 7, or with a C/O ratio of at least 13.5, preferably at least 20, more preferred at least 25.

14. A colloidal graphene dispersion, in particular according to claim 13, having a graphene content of 0.1 % to 0.5 % by weight, preferably about 0.1 % by weight.

15. The colloidal graphene dispersion of claim 13 that does not comprise any dispersant.

16. A multi-graphene dispersion or isolated multi-graphene with an inter-planar distance in the multi-graphene of greater than 3.35 Å, preferably greater than 3.40 Å, or greater than 3.50 Å, or greater than 3.60 Å.

17. Use of a colloidal graphene dispersion as defined in any one of claims 13 to 15 or the method of claim 12 for providing nanoparticles with an electronically conducting coating having a C/O ratio of at least 13.5.

5 18. Use of a multi-graphene obtainable by the method of claim 11 or 12 or as defined in claim 16 as electrode material in rechargeable lithium ion batteries.

19. Use of a multi-graphene with low C/O ratio as obtainable by the method of claim 11 or 12 as electrode material in rechargeable lithium ion batteries.

10 20. A method for generating electronically conducting nanoparticles comprising the step of coating nanoparticles with a graphene dispersion of any one of claims 13 to 15 or coating nanoparticles with a graphene oxide dispersion and then thermally reducing said coated particles in dispersion to get nanoparticles coated with graphene/multi-graphene of a C/O ratio of at
15 least 13.5.

21. A method for preparing an electrode for rechargeable lithium ion batteries comprising the step of providing a multi-graphene by the method of claim 11 or 12 or as defined in claim 16 and coating a conductor with said multi-graphene, optionally in the presence of a binder.

20 22. A method for preparing an electrode for rechargeable lithium ion batteries comprising the step of providing a multi-graphene with low C/O ratio of at most 13, and coating a conductor with said multi-graphene, optionally in the presence of a binder.
