(57) **ABSTRACT**

An ink cartridge includes an ink bag that is configured to store ink inside, a spout that is provided on the ink bag and includes a hollow portion that leads from a first opening to a second opening, and a case that houses the ink bag, an end portion of the case on a side of the second opening including at least a first corner portion, a second corner portion, and a first surface portion, a width in a first direction being smaller than a width in a second direction in the case, an axial line of the spout being, in the second direction, located closer to one end portion of the case on a side having the first corner portion, and the leading end portion of the spout being located inside of the case with respect to the line connecting the first corner portion and the second corner portion.

1 INK CARTRIDGE

CROSS-REFERENCE TO RELATED APPLICATION

This application claims priority to Japanese Patent Application Nos. 2010-293353, 2010-293360, 2010-293364, and 2010-293367, respectively filed Dec. 28, 2010, the content of which is hereby incorporated herein by reference.

BACKGROUND

The present disclosure relates to an ink cartridge including an ink bag that stores ink and a case that houses the ink bag.

Generally, an inkjet printer (hereinafter referred to as a printer) is configured such that an ink cartridge for supplying ink to a print head can be attached to and detached from the printer. An ink cartridge that includes an ink bag, a spout, and a case is known as a general ink cartridge. In this type of ink cartridge, the ink bag may have flexibility and may store ink therein. The spout may be provided to be connected to the ink bag, and may be used to draw out the ink. The case may have a rectangular parallelepiped shape and may house the ink bag.

SUMMARY

The ink bag of the above-described known ink cartridge may have flexibility. Therefore, when the remaining amount of ink becomes small during printing, inner surfaces of the ink bag may come into contact with each other and the ink may be divided. Specifically, part of the ink may not reach the spout and may remain in an ink storage pack.

Various embodiments of the broad principles derived herein provide an ink cartridge that is capable of collecting remaining ink toward a spout and inhibiting the ink from leaking to the outside of a case when a remaining ink amount is small.

Embodiments provide an ink cartridge that includes an ink bag that at least includes two layers of flexible sheets disposed to face each other, that is formed in a bag shape, and that is configured to store ink inside, and a spout that is provided on the ink bag and that includes a hollow portion that leads from a first opening to a second opening. The first opening is communicatively connected with the ink bag. The second opening is provided in a leading end portion of the spout and is open to an outside of the ink bag. The ink cartridge also includes a case that houses the ink bag and whose longitudinal direction is an axial direction of the spout that is provided on the ink bag that is housed. An end portion of the case on a side of the second opening includes at least a first corner portion, a second corner portion, and a first surface portion. The first corner portion is a corner portion that, in the axial direction of the spout, is located on a side of the first opening with respect to the leading end portion of the spout. The second corner portion is a corner portion that, in the axial direction of the spout, is located on a side opposite to the first opening with respect to the leading end portion of the spout. The first surface portion extends from the first corner portion in the axial direction of the spout. A width in a first direction is smaller than a width in a second direction in the case. The first direction is a direction that is orthogonal to an extending direction of a line connecting the first corner portion and the second corner portion and to the axial direction. The second direction is a direction that is orthogonal to the first direction and to the axial direction. An axial line of the spout is, in the second direction, located closer to one end portion of the case on a side having the first corner portion. The leading end

2

portion of the spout is located inside of the case with respect to the line connecting the first corner portion and the second corner portion.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments will be described below in detail with reference to the accompanying drawings in which:

FIG. 1 is a schematic view showing a schematic configuration of an inkjet printer;

FIG. 2 is a perspective view of an ink cartridge as viewed from the rear right;

FIG. 3 is an exploded perspective view of a case;

FIG. 4 is an explanatory view showing the ink cartridge in a state in which a lid portion is removed, as viewed from a left side surface;

FIG. 5 is an enlarged vertical cross-sectional view of a spout surrounding portion of the ink cartridge;

FIG. 6 is a front view of the ink cartridge;

FIG. 7 is an enlarged partial cross-sectional view of the spout surrounding portion of the ink cartridge when ink is supplied;

FIG. 8 is an explanatory view showing a process in which the ink is collected by tilting the ink cartridge;

FIG. 9 is another explanatory view showing a process in which the ink is collected by tilting the ink cartridge;

FIG. 10 is yet another explanatory view showing a process in which the ink is collected by tilting the ink cartridge;

FIG. 11 is an enlarged vertical cross-sectional view of a spout surrounding portion of an ink cartridge according to a first modified example;

FIG. 12 is an enlarged vertical cross-sectional view of a spout surrounding portion of an ink cartridge according to a second modified example;

FIG. 13 is an enlarged vertical cross-sectional view of a spout surrounding portion of an ink cartridge according to a third modified example;

DETAILED DESCRIPTION

Hereinafter, an embodiment of the present disclosure will be explained with reference to the appended drawings.

In the present embodiment, an ink cartridge **1** that is used for an inkjet printer **100** will be explained. The inkjet printer **100** may perform printing on a fabric such as a t-shirt. First, the inkjet printer **100** will be explained with reference to FIG. **1**. The inkjet printer **100** is a known printer that can perform printing on a fabric, which is a printing medium, by a print head **114** using ink supplied from the ink cartridge **1**. Therefore, the configuration of the inkjet printer **100** will be briefly explained. An up-down direction, a right-left direction and a lower left direction in FIG. **1** respectively correspond to an up-down direction, a right-left direction and a front side of the inkjet printer **100**, and also an up-down direction, a right-left direction and a front side of the ink cartridge **1**.

The inkjet printer **100** includes a housing **101** that has a rectangular box shape. A pair of guide rails **102** that extend in a front-rear direction are provided in a substantially central lower portion in the right-left direction inside the housing **101**. A platen support **103** is supported by the guide rails **102** such that the platen support **103** can be moved in the front-rear direction along the guide rails **102**. A platen **104** is fixed to a substantially center position in the right-left direction of an upper surface of the platen support **103**. The platen **104** is replaceable. The platen **104** is a plate having a generally pentagonal shape in a plan view. A fabric, such as a t-shirt, may be placed on the upper surface of the platen **104**.

Although not shown in detail in the drawings, the platen support **103**, to which the platen **104** is fixed, may be moved by a platen drive mechanism in the front-rear direction along the guide rails **102**. The platen drive mechanism includes a platen drive motor and a belt transmission mechanism.

A pair of guide rails **112** that extend in the right-left direction are provided above the platen **104** in a substantially center position in the front-rear direction of the housing **101**. A carriage **113** is supported by the guide rails **112** such that the carriage **113** can be moved in the right-left direction along the guide rails **112**. The print head **114** is fixed to a lower portion of the carriage **113**. Although not shown in detail in the drawings, the carriage **113** provided with the print head **114** may be moved by a carriage drive mechanism in the right-left direction along the guide rails **112**. The carriage drive mechanism includes a carriage drive motor and a belt transmission mechanism. Ink may be supplied to the print head **114** via a tube **142** (refer to FIG. 7) from the ink cartridge **1** that is set in a cartridge mounting portion (not shown in the drawings). The cartridge mounting portion is provided inside the housing **101**. A plurality of fine nozzles are provided on a bottom surface of the print head **114**. Droplets of the ink may be discharged downward from the nozzles by driving of piezoelectric elements, and thus printing may be performed on the fabric placed on the platen **104**.

Eight of the ink cartridges **1** can be set in the cartridge mounting portion provided inside the housing **101**. Eight cartridge insertion ports **120** are provided in a lower right portion of a front surface of the housing **101**. Each of the cartridge insertion ports **120** is an opening to insert and remove the ink cartridge **1** into and from an ink storage portion. The inkjet printer **100** of the present embodiment may use the four ink cartridges **1** for white ink, and the ink cartridges **1** that respectively store inks of four colors of cyan, magenta, yellow, and black. A method for supplying ink from the ink cartridge **1** to the inkjet printer **100** will be described below.

The structure of the ink cartridge **1** of the present embodiment will be explained with reference to FIGS. 1 to 5. As shown in FIGS. 1 to 4, the ink cartridge **1** includes a case **2** and an ink pack **7**. The ink pack **7** is housed in the case **2**. Hereinafter, detailed structures of the case **2** and the ink pack **7** will be explained in order. The ink cartridges **1** for five colors, i.e., white, cyan, magenta, yellow, and black, are different only in the color of liquid ink stored in the ink pack **7**, and the structures of the case **2** and the ink pack **7** are the same for all the ink cartridges **1**.

As shown in FIG. 2, the case **2** has a thin generally rectangular box shape as a whole. However, the case **2** is formed such that a lower portion on a rear side including a corner portion is cut out obliquely upward toward the rear. A length in the front-rear direction, a length in the up-down direction and a length in the right-left direction of the case **2** are longer in that order.

As shown in FIG. 3, the case **2** includes a body portion **3** and a lid portion **4**. The body portion **3** includes a right wall **30**, a bottom wall **31**, an upper wall **32**, a rear wall **33**, and a front wall **34** that each have a thin plate shape and respectively form a right side surface, a bottom surface, an upper surface, a rear surface and a front surface of the case **2**. When the ink cartridge **1** is seen in a side view, namely, when the ink cartridge **1** is seen from a direction that is orthogonal to a maximum area portion (the largest surface among the surfaces shown in FIG. 3) of the lid portion **4**, the right wall **30** has a generally pentagonal shape. In a side view, the right wall **30** has such a shape that, among four corner portions that form right angles of a rectangle that is longer in the front-rear

direction, a corner portion including a corner on the lower rear side is obliquely cut out. Specifically, in a side view, the right wall **30** has two long sides extending in the front-rear direction and facing in parallel to each other, two short sides extending in the up-down direction and facing in parallel to each other, and an oblique side that connects a shorter one of the two long sides and a shorter one of the two short sides.

The bottom wall **31**, the upper wall **32**, the rear wall **33** and the front wall **34** extend substantially perpendicular to the right wall **30** in the same direction and to the same length. The bottom wall **31** connects to a lower end portion of the right wall **30**, namely, the shorter one of the pair of long sides. The upper wall **32** connects to an upper end portion of the right wall **30**, namely, a longer one of the pair of long sides. The rear wall **33** includes the rear surface portion **331** and an inclined surface portion **332**. The rear surface portion **331** connects to a rear end portion of the right wall **30**, namely, the shorter one of the pair of short sides. The inclined surface portion **332** connects to the oblique side of the right wall **30**. The inclined surface portion **332** connects the bottom wall **31** and the rear surface portion **331**. The inclined surface portion **332** is provided with a penetration portion **338** in the vicinity of an end portion where the inclined surface portion **332** connects to the bottom wall **31**. The penetration portion **338** is an opening that penetrates the inclined surface portion **332**. The front wall **34** connects to a front end portion of the right wall **30**, namely, a longer one of the short sides. The front wall **34** connects the bottom wall **31** and the upper wall **32**.

As shown in FIG. 4, a corner portion at which the upper wall **32** and the rear surface portion **331** are connected, a corner portion at which the upper wall **32** and the front wall **34** are connected, and a corner portion at which the bottom wall **31** and the front wall **34** are connected each form a right angle. On the other hand, a corner portion at which the inclined surface portion **332** and the bottom wall **31** are connected, and a corner portion at which the inclined surface portion **332** and the rear surface portion **331** are connected each form an obtuse angle. Hereinafter, the bottom wall **31**, the upper wall **32**, the rear wall **33**, and the front wall **34** are referred to as the peripheral walls **31** to **34** when collectively referred to.

As shown in FIG. 3, the lid portion **4** faces the right wall **30** and forms a left side surface of the case **2**. The lid portion **4** is a thin plate member and has a shape corresponding to the right wall **30** of the body portion **3**. More specifically, when the ink cartridge **1** is seen in a side view, namely, when the ink cartridge **1** is seen from a direction that is orthogonal to a maximum area portion (the largest surface among the surfaces shown in FIG. 3) of the lid portion **4**, the lid portion **4** has a generally pentagonal shape. In a side view, the lid portion **4** has such a shape that, among four corners forming right angles of a rectangle that is longer in the front-rear direction, a corner portion including a corner on the lower rear side is obliquely cut out. The lid portion **4** is joined to the body portion **3** to form the case **2**. A method for joining the lid portion **4** to the body portion **3** is not particularly limited. Although not shown in the drawings, for example, the body portion **3** and the lid portion **4** may be provided with an engagement hole and an engagement pin, respectively. The lid portion **4** may be joined to the body portion **3** by inserting the engagement pin into the engagement hole. The lid portion **4** may be joined to the body portion **3** using an engagement hook and an engagement hole, instead of using the engagement pin. The body portion **3** and the lid portion **4** may be fixed by welding.

As shown in FIG. 4, the ink pack **7** is housed inside the case **2**, in a space that is surrounded by the peripheral walls **31** to **34**. The ink pack **7** includes an ink bag **71** and a spout **72**,

5

which is provided on the ink bag 71. The ink bag 71 of the present embodiment is a bag-shaped container that is formed in the following manner. Two rectangular-shaped resin sheets are overlapped with each other such that inner surfaces of the sheets face each other, and a surrounding portion 716 along four sides is thermally welded (heat sealed). The resin sheets have flexibility. Ink may be stored inside an ink storage portion 717 that is a space surrounded by the surrounding portion 716. The ink storage portion 717 has a generally rectangular shape when seen from a direction that is substantially orthogonal to a sheet surface, namely, a maximum area portion (the largest surface among the surfaces shown in FIG. 4) of the sheet surface. The ink storage portion 717 may extend along inner surfaces of the case 2.

It is sufficient if the ink bag 71 includes two layers of flexible sheets that are disposed to face each other and the ink bag 71 is a bag-shaped container in which a space is formed that can store ink between the sheets. Therefore, for example, the ink bag 71 may be formed such that one rectangular sheet is folded in half to form two layers, and the two layers are joined along three sides other than a folded portion. Two sheets that face each other may be joined along three sides of the two sheets and the remaining one side of each of the two sheets may be joined to another sheet, thus forming the ink bag 71 having a bottom portion. The ink bag 71 may be formed such that four sides of two sheets that face each other are respectively joined to other sheets serving as gussets. A method for joining the sheets is not limited to welding and another method such as adhesive bonding, for example, may be used.

As shown in FIGS. 4 and 5, the spout 72 includes a cylindrical-shaped body portion 721 and connection portions 722. The connection portions 722 are two blade-shaped members that protrude in directions opposite to each other from an outer peripheral surface of the body portion 721, and are provided on one end side of the body portion 721. The spout 72 is provided on the ink bag 71 such that an axial line X of the body portion 721 (more precisely, a hollow portion 700 that will be described below) is substantially in parallel with a longitudinal direction of the ink bag 71. The axial line X is located closer to one end portion of the ink bag 71 in a direction (a shorter direction of the ink bag 71) that is orthogonal to the axial line X. In the present embodiment, the spout 72 is provided in the vicinity of one of four corner portions of the ink bag 71. Hereinafter, of two end portions of the ink bag 71 that are located in the direction orthogonal to the axial line X direction, the end portion that is closer to the axial line X is referred to as a first end portion 711 and the end portion that is farther from the axial line X is referred to as a second end portion 712. Of two end portions of the ink bag 71 that are located in the axial line X direction (the longitudinal direction of the ink bag 71), the end portion that is provided with the spout 72 is referred to as a third end portion 713 and the other end portion is referred to as a fourth end portion 714.

In the present embodiment, the spout 72 is fixed to the ink bag 71 such that one end portion of the body portion 721 that includes the connection portions 722 is inserted between the two sheets that form the ink bag 71, and the one end portion is welded integrally with the surrounding portion 716. The other end portion of the body portion 721 that is not welded with the surrounding portion 716 protrudes from the third end portion 713 of the ink bag 71 to the outside of the ink bag 71.

As shown in FIG. 5, the body portion 721 includes two flanges 727 and 728 that are provided along the outer periphery of the body portion 721. Further, the body portion 721 includes the hollow portion 700 inside the body portion 721. The hollow portion 700 leads from a first opening 701 to a

6

second opening 702. The first opening 701 is communicatively connected to the ink storage portion 717 of the ink bag 71. The second opening 702 opens to the outside of the ink bag 71. A cylindrical rubber plug 723 is inserted into an end portion on the second opening 702 side of the hollow portion 700. Therefore, the second opening 702 is closed by the rubber plug 723. In this manner, the ink may be stored in the ink storage portion 717 in a sealed state. It is sufficient if the spout 72 is provided on the ink bag 71 such that the ink storage portion 717 communicates with the outside through the hollow portion 700, and a method for fixing the spout 72 is not limited to welding. Therefore, for example, the spout 72 may be formed integrally with the ink bag 71.

An arrangement relationship between the case 2 and the ink pack 7 will be explained in detail with reference to FIGS. 4 and 5. As shown in FIG. 4, the ink pack 7 is housed in the case 2 such that the axial line X of the spout 72 substantially match the longitudinal direction (the front-rear direction) of the case 2. The ink pack 7 is housed in the case 2 such that the two layers of sheets that form the ink bag 71 extend substantially in parallel with a virtual plane that includes the axial line X of the spout 72 and forms a right angle with an outer surface 333 (refer to FIG. 5) of the inclined surface portion 332. Therefore, in the present embodiment, outer surfaces of the two layers of sheets extend respectively facing inner surfaces of the right wall 30 and the lid portion 4. The outer surface of one of the two layers of sheets that form the ink storage portion 717 may be adhered to the inner surface of one of the right wall 30 and the lid portion 4.

The sheets that form the ink bag 71 have flexibility. Therefore, when the amount of the remaining ink stored in the ink storage portion 717 is large, the two layers of sheets may curve in directions in which the two layers of sheets are separated from each other. When the remaining amount of the ink is small, the distance between the two layers of sheets may reduce and the two layers of sheets may deflect in directions in which the two layers of sheets come into contact with each other. In summary, because the sheets are not fixed flat surfaces, the sheets are not exactly in parallel with the above-described virtual plane. Therefore, the phrase "substantially in parallel" used in the relationship with the above-described virtual plane includes not only an accurate parallel relationship between flat surfaces, but also an almost parallel state in which deflection of the sheets is allowed.

Further, for example, when the body portion 3 of the case 2, namely, the right wall 30 and the peripheral walls 31 to 34 are integrally formed of resin, generally, a draft angle is provided in order to facilitate release from a cavity of a die. In this case, the right wall 30 and each of the peripheral walls 31 to 34 form an obtuse angle that is wider than a right angle by 2 to 4 degrees. Therefore, as described above, when the outer surface of the sheet of the ink bag 71 is adhered to the inner surface of the right wall 30, the above-described virtual plane and the sheet are not exactly in parallel with each other. However, in a similar manner to the above-described deflection allowance, even when there is an angle difference corresponding to the draft angle, it can be assumed that the above-described virtual plane and the sheet are "substantially in parallel" with each other.

As shown in FIG. 5, in the axial line X direction of the spout 72, the ink pack 7 is housed in the case 2 such that a corner portion, at which the inclined surface portion 332 of the case 2 connects to the bottom wall 31, is located on the first opening 701 side with respect to a leading end portion 724 (a leading end portion of the rubber plug 723) on the second opening 702 side of the spout 72, and such that a corner portion, at which the inclined surface portion 332 connects to

the rear surface portion 331, is located on an opposite side to the first opening 701 with respect to the leading end portion 724. Accordingly, a line L that connects these two corner portions with the shortest distance obliquely intersects the axial line X. Hereinafter, regarding an end portion of the case 2 in the vicinity of the second opening 702 of the spout 72, in the axial line X direction of the spout 72, the corner portion of the case 2 that is located on the first opening 701 side with respect to the leading end portion 724 is referred to as the "first corner portion 334", and the corner portion that is located on the opposite side to the first opening 701 with respect to the leading end portion 724 is referred to as the "second corner portion 335". In the present embodiment, the corner portion at which the inclined surface portion 332 connects to the bottom wall 31 is the first corner portion 334, and the corner portion at which the inclined surface portion 332 connects to the rear surface portion 331 is the second corner portion 335.

As shown in FIG. 5, the bottom wall 31 extends from the first corner portion 334 in the axial line X direction of the spout 72. A rear end portion of the bottom wall 31 (a front side portion of the first corner portion 334) that is located below the spout 72 is referred to as a receiving surface portion 310. Although details will be described below, the receiving surface portion 310 functions as a surface portion to receive ink leaking from the spout 72 below the spout 72.

The ink pack 7 is disposed such that the leading end portion 724 of the spout 72 is located toward the inside of the case 2 with respect to the line L. In the axial line X direction, the leading end portion 724 is located with a clearance from the inner surface (the right surface in FIG. 5) of the inclined surface portion 332. Therefore, ink can move between the inclined surface portion 332 and the leading end portion 724 (on the lower side of the leading end portion 724 in FIG. 5). In the present embodiment, the inclined surface portion 332 is provided between the first corner portion 334 and the second corner portion 335. The outer surface 333 of the inclined surface portion 332 is on the line L. The leading end portion 724 is located on the inner side with respect to the inner surface of the inclined surface portion 332. It is sufficient if the leading end portion 724 is located toward the inside of the case 2 with respect to the line L (the outer surface 333). Although details will be described below, a portion that extends from the first corner portion 334 to the penetration portion 338 of the inclined surface portion 332 may function as a surface portion that inhibits the ink received by the receiving surface portion 310 from leaking to the outside of the case 2.

In the present embodiment, a direction (hereinafter referred to as a first direction) that is orthogonal to the extending direction of the line L and the axial line X direction is the right-left direction of the case 2. A direction (hereinafter referred to as a second direction) that is orthogonal to the first direction and the axial line X direction is the up-down direction of the case 2. As shown in FIG. 6, a width (a distance from the left side surface to the right side surface) W3 in the right-left direction of the case 2 is smaller than a width (a distance from the bottom surface to the upper surface, or a height of the right wall 30 and the lid portion 4) W4 in the up-down direction of the case 2.

The ink pack 7 is housed in the case 2 such that, in the second direction, the axial line X is located closer to one end portion of the case 2 on the side including the first corner portion 334. In the present embodiment, the second direction is the up-down direction of the case 2, as described above. Accordingly, in the up-down direction, the one end portion of the case 2 on the side including the first corner portion 334 is

an end portion on the bottom wall 31 side. Therefore, as shown in FIG. 4, the axial line X is located closer to the end portion on the bottom wall 31 side in the up-down direction of the case 2. The spout 72 is disposed in the vicinity of the first corner portion 334. Taking the axial line X as a boundary, a width W1 (a distance between the axial line X and the first end portion 711) of the ink bag 71 on the bottom wall 31 side is smaller than a width W2 (a distance between the axial line X and the second end portion 712) of the ink bag 71 on the upper wall 32 side.

As shown in FIG. 5, the penetration portion 338 is provided in the inclined surface portion 332, at a position that faces the second opening 702 of the spout 72. Accordingly, the penetration portion 338 is located on the axial line X of the spout 72. As described above, the second opening 702 is closed by the rubber plug 723. Therefore, actually, the penetration portion 338 faces the rubber plug 723.

A method for supplying ink from the ink cartridge 1 to the print head 114 of the inkjet printer 100 will be explained with reference to FIGS. 1 and 7. As shown in FIG. 1, when printing is performed, a user may insert the ink cartridge 1 into the cartridge insertion port 120 of the inkjet printer 100. At this time, the user may insert the ink cartridge 1 from the rear wall 33 side, with the bottom wall 31 of the ink cartridge 1 being on the lower side. The rear wall 33 is provided with the penetration portion 338 (refer to FIG. 2) that faces the second opening 702 (the rubber plug 723).

As shown in FIG. 7, the ink cartridge 1 may be set such that the bottom wall 31 is placed on a placement surface 130 of the cartridge mounting portion. The placement surface 130 is a flat surface that extends in a substantially horizontal direction. Therefore, the ink cartridge 1 may be set in the inkjet printer 100 such that the bottom wall 31 and the axial line X of the spout 72 extend substantially horizontally. A connection portion 140 including a hollow needle 141 is provided inside the cartridge mounting portion, at a position facing the penetration portion 338 (the spout 72) when the ink cartridge 1 is set. A tube 142 is connected to the connection portion 140. The tube 142 may lead the ink drawn out from the ink bag 71 to the print head 114. When the ink cartridge 1 is set in the cartridge mounting portion, the hollow needle 141 of the connection portion 140 pierces a central portion of the rubber plug 723 through the penetration portion 338. The hollow needle 141 may penetrate the rubber plug 723 and a leading end portion of the hollow needle 141 may be disposed inside the hollow portion 700. The leading end portion of the hollow needle 141 is provided with a hole through which ink flows. The ink in the ink storage portion 717 may be supplied to the print head 114 via the first opening 701, the inside of the hollow portion 700, the hollow needle 141, and the tube 142.

When the ink cartridge 1 is initially used, the ink storage portion 717 of the ink bag 71 may be completely filled with ink. Accordingly, the inner surfaces of the two layers of sheets that form the ink bag 71 may be separated from each other, with the ink interposed between the inner surfaces. While printing is performed, the ink may be discharged from the print head 114 little by little in order to form an image on the fabric. When the ink is discharged, a substantially some amount of ink as a discharge amount may be sucked from the ink cartridge 1, and the sucked ink may be supplied to the print head 114. The ink stored in the ink storage portion 717 may gradually reduce as the ink is consumed by printing, and the ink bag 71 may contract. As a result, the inner surfaces of the two layers of flexible sheets may come closer to each other.

When the amount of the remaining ink reduces to a certain extent, the inner surfaces of the sheets may come into contact

with each other in various locations in the ink bag 71. As a result, the ink may be divided by portions where the inner surfaces of the sheets come into contact with each other, due to surface tension of the ink, gravitational force, and the like, for example. In this case, a plurality of ink deposits may exist that are isolated in the ink storage portion 717. Further, in a state in which the bottom wall 31 is placed on the substantially horizontal placement surface 130, the two layers of sheets of the ink bag 71 are disposed such that the surfaces of the sheets extend substantially in the up-down direction. Therefore, due to the gravitational force, part of the ink may flow downward along the inner surface of the sheet and may be accumulated along the first end portion 711 (refer to FIG. 4) inside the ink storage portion 717. As the ink reduces, the ink surface may become lower than the hole in the leading end portion of the hollow needle 141. In this case, even when the ink still remains in the ink storage portion 717, it is difficult to suck the remaining ink because a suction force of the print head 114 is weak.

Even when it is difficult to suck the ink in this manner, the ink cartridge 1 of the present embodiment can be removed from the inkjet printer 100, and owing to the above-described structure, the ink remaining in the ink storage portion 717 can be effectively collected toward the spout 72, more specifically, toward the first opening 701. This operational effect will be explained with reference to FIGS. 8 to 10. As shown in FIG. 8, the user may place the ink cartridge 1, in which the remaining ink amount is reduced and part of the ink is accumulated along the first end portion 711, on a support surface 9 that is a substantially horizontal plane, with the first corner portion 334 and the second corner portion 335 of the ink cartridge 1 being on the lower side. At this time, the user may place the ink cartridge 1 such that the first corner portion 334 and the second corner portion 335 come into contact with the support surface 9. Accordingly, the axial line X direction that substantially matches the longitudinal direction of the ink storage portion 717 is closer to upright than when ink is supplied in the inkjet printer 100.

In the present embodiment, the inclined surface portion 332 connects to the first corner portion 334 and the second corner portion 335, and has the outer surface 333 on the line L (refer to FIG. 5) that connects the first corner portion 334 and the second corner portion 335. Therefore, together with the first corner portion 334 and the second corner portion 335, the inclined surface portion 332 may also come into contact with the support surface 9 and may be supported by the support surface 9. The support surface 9 may be a flat surface, such as a desk top surface, or may not be a flat surface. The leading end portion 724 on the second opening 702 (refer to FIG. 5) side of the spout 72 is located toward the inside of the case 2 with respect to the line L (the outer surface 333). Therefore, when the first corner portion 334 and the second corner portion 335 come into contact with the support surface 9, the spout 72 does not come in contact with the support surface 9.

In the ink cartridge 1, the longitudinal direction (the axial line X of the spout 72) of the case 2 and the ink bag 71 may incline with respect to the horizontal direction. At this time, the second opening 702 of the spout 72 may be directed obliquely downward. The first end portion 711 of the ink bag 71 may incline with respect to the horizontal direction. In a similar manner to when the bottom wall 31 is placed on the substantially horizontal placement surface 130, the two layers of sheets that form the ink storage portion 717 may be disposed such that the surfaces of the two layers of sheets extend substantially in the up-down direction. Part of the ink may move in the ink storage portion 717 due to force that is applied

when the posture of the ink cartridge 1 is changed. In a state in which the axial line X of the spout 72 is substantially horizontal (refer to FIGS. 4 and 6) before the posture of the ink cartridge 1 is changed, the ink dispersed in the ink storage portion 717 may not move because the inner surfaces of the sheets are in contact with each other. At this time, the direction of the gravitational force applied to the dispersed ink may be substantially perpendicular to the axial line X of the spout 72. On the other hand, when the posture of the ink cartridge 1 is changed as shown in FIG. 8, the direction of the gravitational force applied to the dispersed ink may change to an oblique direction with respect to the axial line X of the spout 72.

After the posture of the ink cartridge 1 has been changed in this manner, the user may continue to hold the ink cartridge 1 in an inclined state for a while. In this case, as shown in FIG. 9, the ink in the ink storage portion 717 may start to move downward along the inner surface of the sheet due to the gravitational force and the movement of the ink along with the above-described change in posture. As described above, the surfaces of the sheets extend substantially in the up-down direction, and thus the ink can move smoothly downward. The ink accumulated along the first end portion 711 inside the ink storage portion 717 may flow toward the first corner portion 334 along the first end portion 711 because the first end portion 711 is inclined with respect to the horizontal direction. The spout 72 is provided in the vicinity of the first corner portion 334. Some of the isolated plurality of ink deposits may start to move downward due to the gravitational force. A part of the ink deposits may flow and join with another ink deposit in the middle of downward movement to thereby form a larger ink deposit, and the larger ink deposit may move downward. In this manner, the ink may flow toward the spout 72 along the first end portion 711.

The first corner portion 344 forms an obtuse angle. In the case 2, the axial line X of the spout 72 is located closer to the end portion on the bottom wall 31 side having the first corner portion 334. Therefore, when the ink cartridge 1 is inclined such that the first corner portion 334 and the second corner portion 335 are positioned on the lower side and the inclined surface portion 332 is positioned substantially horizontally, the spout 72 may be disposed in a position that is closer to the support surface 9. As a result, the ink may easily collect in the vicinity of the first opening 701 of the spout 72. Further, the axial line X is located closer to one end portion (the first end portion 711) of the ink bag 71 in the direction that is orthogonal to the axial line X. Taking the axial line X as a boundary, the width of the ink bag 71 on the first end portion 711 side is smaller than the width of the ink bag 71 on the opposite side. Therefore, when the ink cartridge 1 is inclined such that the inclined surface portion 332 is substantially horizontal, the ink may easily collect in the vicinity of the first opening 701 of the spout 72.

Further, when the ink cartridge 1 continues to be inclined, as shown in FIG. 10, most of the ink that remained in the form of ink deposits in various locations inside the ink storage portion 717 may gather in the vicinity of the first opening 701 of the spout 72. In this state, most of the inner surfaces of the sheets may be in contact with each other in the fourth end portion 714 of the ink bag 71 and the vicinity of the fourth end portion 714. In the longitudinal direction of the ink bag 71, the fourth end portion 714 is located on the side opposite to the side where the spout 72 is provided.

In the state in which the ink is collected in the vicinity of the first opening 701 in this manner, the user may set the ink cartridge 1 in the inkjet printer 100 again, with the wall surface 31 being on the lower side, as shown FIG. 7. As shown

in FIG. 10, more ink may be collected in the vicinity of the first opening 701 as compared to the state shown in FIG. 8. In addition, in the fourth end portion 714 of the ink bag 71 and the vicinity of the fourth end portion 714, most of the inner surfaces of the two sheets may be in contact with each other. Therefore, even when the bottom wall 31 is placed on the placement surface 130 and the first end portion 711 is positioned substantially horizontally, it is possible to inhibit to some extent the movement of the ink from the vicinity of the first opening 701 toward the fourth end portion 714. As a result, it is possible to maintain a state in which the ink surface is above the hole of the leading end portion of the hollow needle 141 that has pierced the rubber plug 723. Thus, the remaining ink can be supplied to the print head 114.

Further, owing to the above-described structure, the ink cartridge 1 of the present embodiment can inhibit the ink that leaks from the spout 72 from leaking from the case 2. This operational effect will be explained with reference to FIG. 7. As described above, when the ink cartridge 1 is set in the inkjet printer 100, the bottom wall 31 may be placed on the placement surface 130. In this case, the receiving surface portion 310 is located below the spout 72. The inclined surface portion 332 extends obliquely upward toward the rear, from the rear end of the receiving surface portion 310, namely, from the first corner portion 334. When ink is supplied, the hollow needle 141 may pierce the rubber plug 723. When the hollow needle 141 is pulled out from the rubber plug 723, there is a possibility that the ink leaks from a through hole that is formed in the rubber plug 723 by the hollow needle 141. Further, in a case where the rubber plug 723 comes loose for some reason, there is a possibility that the ink may leak from a gap between the second opening 702 and the rubber plug 723.

In this type of case, as long as the ink cartridge 1 is disposed such that the bottom wall 31 is directed downward, the ink may drop downward along the leading end portion 724 of the rubber plug 723 and may drop down along the lower end of the body portion 721 due to the surface tension of the ink. In the case 2 of the present embodiment, the receiving surface portion 310, which connects to the first corner portion 334, is provided below the spout 72. Therefore, the receiving surface portion 310 can receive the ink that has dropped down. Further, the portion that extends from the first corner portion 334 to the penetration portion 338 of the inclined surface portion 332 is inclined upward. Therefore, it is possible to reduce a possibility that the ink received by the receiving surface portion 310 moves toward the penetration portion 338 and leaks from the penetration portion 338. Thus, it is possible to reduce a possibility that the inkjet printer 100 and fingers etc. of the user who handles the ink cartridge 1 become stained with the ink.

As explained above, in the ink cartridge 1 of the present embodiment, the longitudinal direction is the axial line X direction of the spout 72 of the ink bag 71. The first corner portion 334 and the second corner portion 335 are provided in the case 2 in which the width W3 in the right-left direction is smaller than the width W4 in the up-down direction. In the axial direction of the spout 72, the first corner portion 334 and the second corner portion 335 are respectively located on the first opening 701 side and the opposite side of the first opening 701 side with respect to the leading end portion 724 of the second opening 702. The receiving surface portion 310 that extends in the direction of the axial line X of the spout 72 is connected to the first corner portion 334. Further, in the case 2, the axial line X of the spout 72 is located closer to the end portion on the bottom wall 31 side having the first corner portion 334. The leading end portion 724 of the spout 72 is

located toward the inside of the case 2 with respect to the line L that connects the first corner portion 334 and the second corner portion 335.

Therefore, when the amount of the remaining ink becomes small, the user can stably place the ink cartridge 1 in an inclined state with respect to the horizontal direction, using the first corner portion 334 and the second corner portion 335 as described above. When the user holds the ink cartridge 1 in the air, there is a possibility that the ink cartridge 1 will slip from the user's hand for some reason and be dropped. At this time, if the ink cartridge 1 is in a posture in which the spout 72 is located on the upper side, the flow of the ink toward the spout 72 may be inhibited. However, as described above, the ink cartridge 1 is adapted for the inclined surface portion 332 to be placed on the substantially horizontal support surface 9. Therefore, when the inclined surface portion 332 is placed on the support surface 9, the downward flow of the ink due to the gravitational force may be stabilized. As a result, the possibility may be reduced that a force in the completely opposite direction is applied to the ink. It is therefore possible to effectively collect the ink remaining in the ink bag 71 toward the spout 72.

In addition, the ink cartridge 1 can be easily held in an inclined state by placing the ink cartridge 1 such that the first corner portion 334 and the second corner portion 335 come into contact with a surface such as a desktop surface. Therefore, as compared to a case in which the user grasps the ink cartridge 1 in an inclined state in the air, it is possible to reduce the force required by the user and to improve user-friendliness. In addition, in the present embodiment, the inclined surface portion 332 is provided between the first corner portion 334 and the second corner portion 335. Therefore, it is possible to maintain the inclined state of the ink cartridge 1 in a stable manner more easily. In addition, as described above, by providing the receiving surface portion 310 and the inclined surface portion 332, it is possible to reduce a possibility that the ink that leaks from the spout 72 leaks to the outside of the case 2.

In many cases, pigment ink that contains pigment is used as ink for the inkjet printer 100. Therefore, in many cases, the ink bag 71 in the ink cartridge 1 is filled with pigment ink. In a case where the ink cartridge 1 is shaken and the ink in the ink bag 71 is agitated, the ink may be scattered over a wide range in the ink storage portion 717. Even in this type of case, it is possible to collect the remaining ink toward the spout 72 by inclining the ink cartridge 1 with the use of the first corner portion 334 and the second corner portion 335. It is therefore possible to reduce waste of the ink. In a white ink that contains titanium oxide, the titanium oxide is likely to be precipitated. However, with the ink cartridge 1 of the present embodiment, when the ink cartridge 1 is inclined using the first corner portion 334 and the second corner portion 335, the axial direction of the spout 72 becomes oblique with respect to the horizontal direction. Therefore, compared to a case in which the axial line X is oriented vertically, titanium oxide is less likely to be precipitated in the first opening 701 of the spout 72. It is therefore possible to inhibit a state in which the ink cannot be used for printing as a result that titanium oxide is precipitated in the first opening 701 and an ink composition is divided into two parts, for example.

Emulsion ink that contains emulsion is also used in many cases as ink for the inkjet printer 100. The emulsion ink has high viscosity as compared to an ink that does not contain emulsion. Therefore, even when the ink cartridge 1 is inclined, it is more difficult for the ink to move and it takes time to collect the ink downward. According to the ink cartridge 1 of the present embodiment, it is possible to easily

hold the ink cartridge **1** in an inclined state by placing the ink cartridge **1** such that the first corner portion **334** and the second corner portion **335** come into contact with a support surface, such as a desktop surface. This is particularly advantageous as compared to a case in which the user holds an ink cartridge **1** for a long time in the air. In addition, when the emulsion ink also contains titanium oxide, it is possible to effectively collect the emulsion ink while inhibiting precipitation of titanium oxide in the first opening **701** of the spout **72**, as described above.

The case **2** is provided with the inclined surface portion **332** that connects the first corner portion **334** and the second corner portion **335**. It is therefore possible to alleviate an impact that is received by the spout **72** when the ink cartridge **1** is dropped. Specifically, the first corner portion **334**, where the inclined surface portion **332** of the case **2** connects to the bottom wall **31**, forms an obtuse angle. The spout **72** is disposed in the vicinity of the first corner portion **334**. When an impact is applied to this type of obtuse angle corner portion, stress is less likely to concentrate on the corner portion, as compared to a right angle corner portion. Therefore, as compared to the right angle corner portion, it is possible to reduce a possibility that a strong impact is applied to the corner portion and that the spout **72** located in the vicinity is damaged or the disposed position of the spout **72** is displaced significantly. Further, for example, at the time of shipment, it is assumed that the ink cartridge **1** is packed in a rectangular parallelepiped box having substantially the same size as the ink cartridge **1**. In this type of case, a triangular prism-shaped space is formed between the inclined surface portion **332** and the box. As a result, even if the box is dropped, for example, and the ink cartridge **1** receives an impact, this space may serve as a cushion. It is therefore possible to alleviate the impact received by the spout **72**.

As shown in FIG. **5**, in a state in which the axial line **X** of the spout **72** of the ink cartridge **1** is substantially horizontal, the upper surface (the inner surface) of the inclined surface portion **332** projects in the leading end direction of the leading end portion **724**, beyond the lower side of the leading end portion **724**. Therefore, even if the ink drops downward from the leading end portion **724** when the hollow needle **141** is pulled out from the spout **72**, the ink may collide with the upper surface of the inclined surface portion **332**. The ink may move toward the inner side (the first opening **701** side) of the ink cartridge **1** along the slope of the inclined surface portion **332**. Therefore, the vicinity of the ink cartridge **1** may be inhibited from being contaminated with the ink.

Not only when the hollow needle **141** for supplying ink to the inkjet printer **100** is pulled out from the spout **72**, the contamination prevention effect can also be expected in another case. For example, also when a hollow needle that is used to initially fill, add, or refill ink to the ink bag **71** is pulled out, ink may drop. Therefore, also in this type of case, a similar effect can be expected. In the state shown in FIG. **5**, in a case where the ink adheres to the leading end portion **724** in accordance with insertion and removal of the hollow needle **141**, the ink may be located on a lower end portion of the leading end portion **724**. In that ink state, if the ink cartridge **1** is inclined as shown in FIG. **9**, the upper surface (the inner surface) of the inclined surface portion **332** is located below the lower end portion of the leading end portion **724** in the state shown in FIG. **5**. Therefore, even when the ink drops downward from the leading end portion **724**, the ink may collide with the upper surface of the inclined surface portion **332**. Thus, it is possible to suppress the vicinity of the ink cartridge **1** from being contaminated with the ink.

As shown in FIG. **5**, the above-described ink cartridge **1** is an example in which the inclined surface portion **332** is provided between the first corner portion **334** and the second corner portion **335**, and the inclined surface portion **332** has the outer surface **333** on the line **L** that connects the first corner portion **334** and the second corner portion **335**. However, as long as the ink cartridge **1** can be placed such that the first corner portion **334** and the second corner portion **335** come into contact with a substantially horizontal surface and the longitudinal direction of the case **2** can be maintained in an inclined state with respect to the horizontal direction and as long as the receiving surface portion **310** may function to receive the ink with the bottom wall **31** of the ink cartridge **1** being on the lower side, the shape etc. of the first corner portion **334**, the second corner portion **335**, and the vicinity of the first corner portion **334** and the second corner portion **335** can be appropriately modified. Some modified examples will be explained below with reference to FIGS. **11** to **13**.

An ink cartridge **11** of a first modified example shown in FIG. **11** is an example in which, in place of the inclined surface portion **332** (refer to FIG. **5**) of the ink cartridge **1**, a surface portion **336** is provided between the first corner portion **334** and the second corner portion **335**. The surface portion **336** has an outer surface that is substantially in parallel with the line **L**, which connects the first corner portion **334** and the second corner portion **335**, and that is located toward the inside of the case **2** with respect to the line **L**. Similarly to the ink cartridge **1** of the embodiment, the penetration portion **338** is provided in the surface portion **336** at a position that faces the second opening **702** of the spout **72**. The leading end portion **724** of the spout **72** is located toward the inside of the case **2** with respect to the outer surface of the surface portion **336**. The leading end portion **724** is located with a clearance from an inner surface (a right surface in FIG. **11**) of the surface portion **336** in the direction of the axial line **X**. Therefore, ink can move between the surface portion **336** and the leading end portion **724** (below the leading end portion **724** in FIG. **11**).

Also with the ink cartridge **11** having this type of structure, when the amount of the remaining ink becomes small, the ink cartridge **11** can be placed such that the first corner portion **334** and the second corner portion **335** come into contact with the support surface. Thus, the ink cartridge **11** can be held in an inclined position. Therefore, the ink remaining in the ink bag **71** can be effectively collected toward the first opening **701** of the spout **72**. The surface portion **336** that is substantially in parallel with the line **L** is provided on the inner side of the line **L** that connects the first corner portion **334** and the second corner portion **335**. Therefore, even when the ink cartridge **11** is held while being placed such that the first corner portion **334** and the second corner portion **335** come into contact with the support surface such as the desktop surface, the penetration portion **338** does not come into contact with the support surface. Therefore, even when ink adheres to the vicinity of the second opening **702**, it is possible to reduce a possibility that the ink will adhere to the support surface. The leading end portion **724** of the spout **72** is located inwardly from the outer surface of the surface portion **336**. It is therefore possible to protect the spout **72** by the surface portion **336**. Further, when the ink cartridge **11** is placed with the bottom wall **31** directed downward, by using the receiving surface portion **310** and the surface portion **336**, it is possible to reduce a possibility that ink that leaks from the spout **72** leaks to the outside of the case **2**.

In the ink cartridge **11**, a pair of fixing portions **381** and **382** are provided on the bottom wall **31** side and the upper wall **32** side, with the spout **72** interposed between the fixing portions

15

381 and **382**. The pair of fixing portions **381** and **382** are protruding pieces that protrude from the inner surface of the right wall **30** toward the inside of the case **2**. The fixing portion **381** is formed such that the fixing portion **381** is also connected to the receiving surface portion **310** of the bottom wall **31** at a position slightly in front of the first corner portion **334**. The fixing portion **381** is inserted, from below, between the two flanges **727** and **728** that are provided on the outer periphery of the body portion **721** of the spout **72**. The fixing portion **382** is formed such that the fixing portion **382** is also connected to the inclined surface portion **332**. From the rear of the flange **727**, the fixing portion **382** is in contact with a side surface of the flange **727** on the side of the leading end portion **724** provided on the body portion **721**. Thus, the spout **72** can be positioned and fixed by the fixing portions **381** and **382**. Thus, the spout **72** can be reliably disposed in an accurate position with respect to the receiving surface portion **310** and the surface portion **336**. Only one of the fixing portions **381** and **382** may be provided in the case **2**.

An ink cartridge **12** of a second modified example shown in FIG. **12** corresponds to the body portion **3** of the case **2** shown in FIG. **3** in which the inclined surface portion **332** is omitted. Therefore, the body portion **3** includes the right wall **30**, the bottom wall **31**, the upper wall **32**, the rear surface portion **331**, and the front wall **34**. The bottom wall **31**, the upper wall **32**, the rear surface wall **331**, and the front wall **34** are formed continuously with the right wall **30**. When the body portion **3** and the lid portion **4** are bonded, an opening that extends obliquely upward is formed, at a bottom portion of the rear surface side of the case **2**, by rear end portions of the right wall **30**, the bottom wall **31**, and the lid portion **4**, and a lower end portion of the rear surface portion **331**. Therefore, as shown in FIG. **12**, the first corner portion **334** is formed by the rear end portion of the bottom wall **31**. The second corner portion **335** is formed by the lower end portion of the rear surface portion **331**. The rear end portions of the right wall **30** and the lid portion **4** (refer to FIG. **3**), which form the opening, are shorter by the thickness of the bottom wall **31** and the rear surface wall **331**. Therefore, the rear end portions of the right wall **30** and the lid portion **4** are located toward the inside of the case **2** with respect to the line **L** that connects the first corner portion **334** and the second corner portion **335**. In other words, the first corner portion **334** and the second corner portion **335** of the case **2** are protruding more than the rear end portions of the right wall **30** and the lid portion **4**. Both corners of the first corner portion **334** and the second corner portion **335** of the second modified example are rounded off and formed as rounded corner portions.

The ink cartridge **12** includes the fixing portions **381** and **383** that fix the spout **72** to the case **2**. Similarly to the first modified example, the fixing portion **381** protrudes from the right wall **30** toward the inside of the case **2**. The fixing portion **381** is connected to the receiving surface portion **310** at a position slightly in front of the first corner portion **334**. Similarly to the fixing portion **381**, the fixing portion **383** is a protruding piece that protrudes from the right wall **30** toward the inside of the case **2**. The fixing portion **383** is inserted between the two flanges **727** and **728** that are provided on the outer periphery of the body portion **721** of the spout **72** while being disposed such that the body portion **721** is sandwiched, from below and above, between the fixing portions **381** and **383**. It is therefore possible to position and fix the spout **72** by the fixing portions **381** and **383**. Thus, the spout **72** can be reliably disposed in an accurate position with respect to the case **2**.

Similarly to the ink cartridge **1**, even with the ink cartridge **12** that is not provided with the inclined surface portion **332**

16

(refer to FIG. **5**), when the amount of the remaining ink becomes small, the ink cartridge **12** can be placed such that the first corner portion **334** and the second corner portion **335** come into contact with the support surface. Thus, the ink cartridge **12** can be held in an inclined position. Therefore, the remaining ink in the ink bag **71** can be effectively collected toward the first opening **701** of the spout **72**. In a case where a surface portion is located on the line **L** that connects the first corner portion **334** and the second corner portion **335**, depending on a shape of the support surface, the surface portion may come in contact with the support surface. As no surface portion is provided on the line **L**, it is possible to reliably make the first corner portion **334** and the second corner portion **335** come into contact with the support surface. Therefore, it is possible to hold the stable inclined position of the ink cartridge **12**. For example, when the ink cartridge **12** is pulled out from the inkjet printer **100**, there is a case in which the ink cartridge **12** is disposed such that the bottom wall **31** is directed downward. In this type of case, the receiving surface portion **310**, which extends in a substantially horizontal manner, can receive the ink that drops from the spout **72**. Thus, it is possible to reduce a possibility that the ink leaks to the outside of the case **2**.

An ink cartridge **13** of a third modified example shown in FIG. **13** is an example in which, in place of the inclined surface portion **332** of the ink cartridge **1**, a surface portion **337** is provided between the first corner portion **334** and the second corner portion **335**. The surface portion **337** has an outer surface that is not in parallel with the line **L** that connects the first corner portion **334** and the second corner portion **335**. As shown in FIG. **13**, the surface portion **337** connects to the lower end of the rear surface portion **331**. Along the rear end portion of the right wall **30** having an inverted **L**-shape in a side view, the surface portion **337** extends forward and then bends downward, further extending between the two flanges **727** and **728**. The flanges **727** and **728** are provided on the outer periphery of the body portion **721** of the spout **72**. Further, slightly in front of the rear end of the bottom wall **31**, the surface portion **337** extends from the upper surface of the receiving surface portion **310** of the bottom wall **31** (the inner surface of the case **2**) to between the two flanges **727** and **728** of the spout **72**. In the ink cartridge **13**, a rear end portion of the bottom wall **31** is the first corner portion **334**. A corner at which the rear surface portion **331** connects to the surface portion **337** is the second corner portion **335**.

In a case where the remaining amount of ink becomes small, the ink cartridge **13** can be placed such that the first corner portion **334** and the second corner portion **335** come into contact with a support surface. Therefore, the ink cartridge **13** can be held in an inclined state. As a result, it is possible to effectively collect the ink remaining in the ink bag **71** toward the first opening **701** of the spout **72**. For example, when the ink cartridge **13** is pulled out from the inkjet printer **100**, there is a case in which the ink cartridge **13** is disposed such that the bottom wall **31** is directed downward. In this type of case, the receiving surface portion **310** may receive the ink that drops from the spout **72**, and thus it is possible to reduce a possibility that the ink leaks to the outside of the case **2**.

In this example, in order to seal a rear surface lower portion of the case **2** in a state in which the surface portion **337** is in contact with the outer periphery of the body portion **721** of the spout **72**, the case **2** may be divided into the body portion **3** and the lid portion along the center line in the right-left direction, instead of using the method of division shown in FIG. **3**. The bottom wall **31**, the upper wall **32**, the rear surface

17

portion **331**, the surface portion **337**, and the front wall **34** may be provided on each of the body portion **3** and the lid portion. Similarly to the fixing portions **381** (refer to FIG. **11**) in the first modified example, the surface portion **337** has a function to reliably dispose and fix the spout **72** to an accurate position with respect to the case **2**.

Wall surfaces other than the section that corresponds to the inclined surface portion **332** of the ink cartridge **1** of the embodiment can be omitted as long as the case **2** includes the first corner portion **334**, the second corner portion **335**, and the receiving surface portion **310**, and as long as the relationship between the case **2** and the ink pack **7** can be defined as described above. For example, the case **2** may be formed only by the right wall **30** and the lid portion **4** that face each other and the bottom wall **31** that connects the right wall **30** and the lid portion **4**. The ink pack **7** may be disposed between the right wall **30** and the lid portion **4**, and the outer surface of one of the two layers of sheets forming the ink bag **71** may be adhered to the inner surface of one of the right wall **30** and the lid portion **4** that face each other. In this case, unlike the above-described embodiment and modified examples, the bottom wall **31** need not necessarily have a length that extends an entire length of the case **2** in the front-rear direction. For example, only a surface portion that extends from the first corner portion **334** in the direction of the axial line *X* of the spout **72** and that functions to receive the ink may be provided below the spout **72**.

The inclined surface portion **332** shown in FIG. **2** may be formed of hard resin as a part of the case **2**, or the inclined surface portion **332** may be a flexible film (an adhesive tape, for example) that is fixed to the end portion of the case **2**. Further, a member used as the inclined surface portion **332** may be replaceable. The ink cartridges **12** and **13** that are shown in FIGS. **12** and **13** are not provided with the inclined surface portion **332** shown in FIG. **2**. In this type of ink cartridge, an inclined surface may be formed by fixing a flexible film (an adhesive tape, for example) to the end portion of the case **2**. In this case, the film need not necessarily be provided on a whole surface of a section corresponding to the inclined surface portion **332**. The film may be provided on a part of the section corresponding to the inclined surface portion **332**. In the ink cartridge that is not provided with the inclined surface portion **332** shown in FIG. **2**, a flexible film (an adhesive tape, for example) may be provided on a part of the end portion of the case **2**, and the corner portion (at least one of the first corner portion **334** and the second corner portion **335**) of the end portion may be exposed.

When the effect of collecting the ink of the ink cartridge **1** toward the spout **72** is explained above (refer to FIGS. **8** to **10**), an example is given in which the user holds the ink cartridge **1** by hand while causing the first corner portion **334** and the second corner portion **335** to come into contact with the substantially horizontal support surface **9**. However, the ink cartridge **1** may be caused to stand such that the lower end of the front wall **34** of the ink cartridge **1** is brought into contact with a substantially vertical surface (for example, a wall) indicated by a dashed line *Y* in FIG. **8**, while the first corner portion **334** and the second corner portion **335** are brought into contact with the substantially horizontal support surface **9**. In this case, the user need not hold the ink cartridge **1** by hand.

In the embodiment and the modified examples described above, an example is explained in which the case **2** is provided with the rear surface portion **331**, namely, the second corner portion **335** is located at a middle portion in the up-down direction of the rear surface of the case **2**. In this case, the first corner portion **334** and the second corner portion **335** are

18

provided, and at the same time, it is possible to inhibit the case **2** from becoming longer than necessary in the longitudinal direction. In other words, it is possible to reduce a wasteful space that is not used inside the case **2**. However, a rear end portion of the case **2** may have such a shape that the rear end portion is cut out obliquely upward to the rear, from the bottom wall **31** to the upper wall **32**, instead of only cutting out a lower portion of the rear end portion, and a rear end portion of the upper wall **32** may be used as the second corner portion **335**.

The apparatus and methods described above with reference to the various embodiments are merely examples. It goes without saying that they are not confined to the depicted embodiments. While various features have been described in conjunction with the examples outlined above, various alternatives, modifications, variations, and/or improvements of those features and/or examples may be possible. Accordingly, the examples, as set forth above, are intended to be illustrative. Various changes may be made without departing from the broad spirit and scope of the underlying principles.

What is claimed is:

1. An ink cartridge comprising:

an ink bag that at least includes two layers of flexible sheets disposed to face each other to form an ink storage portion configured to store ink inside;

a spout that is provided on the ink bag and that includes a hollow portion that leads from a first opening to a second opening, wherein the first opening is communicatively connected with the ink storage portion, and the second opening is provided in a leading end portion of the spout and is open to an outside of the ink bag; and

a case that houses the ink bag, wherein a longitudinal direction of the case is an axial direction of the spout that is provided on the ink bag, the case comprising:

an end portion on a side of the second opening of the spout, the end portion comprising:

a first corner portion, and

a second corner portion,

wherein the first corner portion is a corner portion that, in the axial direction, is located on a side of the first opening with respect to the leading end portion of the spout, and

wherein the second corner portion is a corner portion that, in the axial direction, is located on a side opposite to the first opening with respect to the leading end portion of the spout, and

a first surface portion and a second surface portion, wherein:

the first surface portion extends from the first corner portion in the axial direction,

the second surface portion is at least partly opposite the first surface portion and extends in the axial direction, and

a length of the first surface portion in the axial direction is different from a length of the second surface portion in the axial direction,

wherein:

a width in a first direction is smaller than a width in a second direction in the case, wherein:

the first direction is a direction that is orthogonal to an extending direction of a line connecting the first corner portion and the second corner portion and to the axial direction, and

the second direction is a direction that is orthogonal to the first direction and to the axial direction,

19

an axial line of the spout is, in the second direction, located closer to the first surface portion extending from the first corner portion than the second surface portion, and

the leading end portion of the spout is located inside of the case with respect to the line connecting the first corner portion and the second corner portion.

2. The ink cartridge according to claim 1, wherein:

the end portion further comprises:

a third surface portion that is a surface that connects to the first surface portion at the first corner portion and that extends substantially in parallel with the line connecting the first corner portion and the second corner portion; and

a penetration portion that is provided in the third surface at a position facing the second opening of the spout, and

the leading end portion of the spout on the side of the second opening is located toward the inside of the case with respect to an outer surface of the third surface portion.

3. The ink cartridge according to claim 2, wherein the outer surface of the third surface portion is on the line connecting the first corner portion and the second corner portion.

4. The ink cartridge according to claim 1, wherein the case further comprises a first fixing portion that is formed continu-

20

ously with the first surface portion and that is configured to fix the spout to the first surface portion.

5. The ink cartridge according to claim 2, wherein the case further comprises a second fixing portion that is formed continuously with the third surface portion and that is configured to fix the spout to the third surface portion.

6. The ink cartridge according to claim 1, wherein:

the case further comprises:

a first side surface that faces one of the two layers of sheets of the ink bag, and

a second side surface that faces the other of the two layers of sheets and that faces the first side surface, the ink bag being interposed between the first side surface and the second side surface,

the first side surface and the second side surface are disposed to be separated from each other in the first direction, and

a distance between the first side surface and the second side surface is shorter than a width of each of the first side surface and the second side surface in the second direction.

7. The ink cartridge according to claim 1, wherein the axial line of the spout is arranged, in the second direction, to intersect the end portion of the case at a point closer to the first corner portion than the second corner portion.
