Priority Claims/Related Applications

This application is a continuation in part of and claims priority under 35 USC 120 to U.S. Patent Application Serial No. 14/303,541, filed on June 12, 2014 and entitled "Dynamically Adjustable Multiphasic Defibrillator Pulse System And Method" which in turn claims priority under 35 USC 120 and claims the benefit under 35 USC 119(e) to U.S. Provisional Patent Application Serial No. 61/835,443 filed June 14, 2013 and titled "Dynamically Adjustable Multiphasic Defibrillator Pulse System and Method", the entirety of which is incorporated herein by reference.

Field

The disclosure relates to medical devices and in particular to devices and methods that generates and delivers therapeutic electrical treatment pulses used in medical devices, such as cardioverters and defibrillators, neuro-stimulators, musculo-skeletal stimulators, organ stimulators and nerve/peripheral nerve stimulators. More specifically the disclosure relates to the generation and delivery/use by such medical devices of a new and innovatively shaped family/generation of biphasic or multiphasic pulse waveforms.

Background

It is well known that a signal having a waveform may have a therapeutic benefit when the signal is applied to a patient. For example, the therapeutic benefit to a patient may be a treatment that is provided to the patient. The therapeutic benefit or therapeutic treatment may include stimulation of a part of the body of the patient or treatment of a sudden cardiac arrest of the patient. Existing systems that apply a signal with a waveform to the patient often generate and apply a well-known signal waveform and do not provide much, or any, adjustability or variability of the signal waveform.

In the context of defibrillators or cardioverters, today's manual defibrillators deliver either an older style Monophasic Pulse (a single high energy single polarity pulse) or the now more
common Biphasic Pulse (consisting of an initial positive high energy pulse followed by a smaller inverted negative pulse). Today's implantable cardioverter defibrillators (ICDs), automated external defibrillators (AEDs) and wearable cardioverter defibrillators (WCDs) all deliver Biphasic Pulses with various pulse phase lengths, high initial starting pulse amplitude and various pulse slopes. Each manufacturer of a particular defibrillator, for commercial reasons, has their own unique and slightly different exact timing and shape of the biphasic pulse for their devices' pulses, although they are all based off of the standard biphasic waveform design. Multiple clinical studies over the last couple of decades have indicated that use of these variants of the biphasic waveform has greater therapeutic value than the older monophasic waveform does to a patient requiring defibrillation therapy and that these standard biphasic waveforms are efficacious at appreciably lower levels of energy delivery than the original monophasic waveforms, and with a higher rate of resuscitation success on first shock delivery.

Thus, almost all of the current defibrillator products that use a biphasic waveform pulse have a single high-energy reservoir, which, while simple and convenient, results in severe limitation on the range of viable pulse shapes that can be delivered. Specifically, the second (or Negative) phase of the Biphasic waveform is currently characterized by a lower amplitude starting point than the first (or Positive) phase of the Biphasic waveform, as shown in Figure 2. This is due to the partial draining of the high-energy reservoir during delivery of the initial Positive phase and then, after inverting the polarity of the waveform so that the Negative phase is able to be delivered, there is only the same partially drained amount of energy remaining in the energy reservoir. This lower amplitude starting point constrains and causes the lower initial amplitude of the Negative phase of the waveform. The typical exponential decay discharge is shown by the Positive phase of the waveform shown in Figure 2.

The standard biphasic pulse waveform has been in common usage in manual defibrillators and in AEDs since the mid-1990s, and still results in energy levels of anywhere from 120 to 200 joules or more being delivered to the patient in order to be efficacious. This results in a very high level of electrical current passing through the patient for a short period of time which can lead to skin and flesh damage in the form of burns at the site of the electrode pads or paddles in addition to the possibility of damage to organs deeper within the patient's body, including the heart itself. The significant amounts of energy used for each shock and the
large number of shocks that these AED devices are designed to be able to deliver over their lifespan, has also limited the ability to further shrink the size of the devices.

WCDs generally need to deliver shocks of 150-200 joules in order to be efficacious, and this creates a lower limit on the size of the electrical components and the batteries required, and hence impacts the overall size of the device and the comfort levels for the patient wearing it.

ICDs, given that they are implanted within the body of patients, have to be able to last for as many years as possible before their batteries are exhausted and they have to be surgically replaced with a new unit. Typically ICDs deliver biphasic shocks of up to a maximum of 30-45 joules, lower than is needed for effective external defibrillation as the devices are in direct contact with the heart tissue of the patient. Subcutaneous ICDs, differ slightly in that they are not in direct contact with the heart of the patient, and these generally deliver biphasic shocks of 65-80 joules in order to be efficacious. Even at these lower energy levels there is significant pain caused to the patient if a shock is delivered in error by the device. Most existing devices are designed to last for between 5-10 years before their batteries are depleted and they need to be replaced.

Another, equally common type of defibrillator is the Automated External Defibrillator (AED). Rather than being implanted, the AED is an external device used by a third party to resuscitate a person who has suffered from sudden cardiac arrest. Figure 9 illustrates a conventional AED 800, which includes a base unit 802 and two pads 804. Sometimes paddles with handles are used instead of the pads 804. The pads 804 are connected to the base unit 802 using electrical cables 806.

A typical protocol for using the AED 800 is as follows. Initially, the person who has suffered from sudden cardiac arrest is placed on the floor. Clothing is removed to reveal the person's chest 808. The pads 804 are applied to appropriate locations on the chest 808, as illustrated in Figure 9. The electrical system within the base unit 802 generates a high voltage between the two pads 804, which delivers an electrical shock to the person. Ideally, the shock restores a normal cardiac rhythm. In some cases, multiple shocks are required.

**Description of the Drawings**

Figure 1 illustrates a medical device that may generate and deliver a biphasic or multiphasic waveform;
Figure 2 illustrates a standard biphasic pulse waveform where the second (negative) phase of the waveform is smaller in amplitude than that of the first (positive) phase of the waveform. 

Figure 3 illustrates the shape of a biphasic waveform where the first phase of the waveform is identical in amplitude to that of the second phase of the waveform.

Figures 4A and 4B illustrate the shape of a biphasic pulse waveform where the first phase of the waveform is slightly smaller in amplitude than that of the second phase of the waveform.

Figure 5 illustrates the shape of a biphasic pulse waveform where the first phase of the waveform is significantly smaller in amplitude than that of the second phase of the waveform.

Figure 6 illustrates the shape of a biphasic pulse waveform where the first phase of the waveform is significantly smaller in amplitude than that of the second phase of the waveform, and where the first phase is a negative phase and the second phase is a positive phase.

Figure 7 illustrates the shape of a multiphasic pulse waveform where the initial phase of the waveform is smaller in amplitude than the second phase of the waveform, regardless of the amplitude(s) of any phase(s) subsequent to the second phase of the waveform.

Figure 8 diagrammatically illustrates an example of a conventional implantable cardioverter defibrillator.

Figure 9 diagrammatically illustrates an example of a conventional external defibrillator.

Figure 10 illustrates a biphasic waveform where the first phase of the waveform is significantly smaller in amplitude than the amplitude of the second phase of the waveform and a range of phase tilt variables for each of the phases are shown diagrammatically.

Figure 11 illustrates a biphasic waveform where each phase of the waveform (equal in size to each other) is switched on and off throughout the delivery process such that only a fraction of the maximum possible energy is actually delivered to the patient.

Figure 12 illustrates a biphasic waveform where each phase of the waveform, where the first phase is smaller in amplitude than the second phase, is switched on and off throughout the delivery process such that only a fraction of the maximum possible energy is actually delivered to the patient.

**Detailed Description of One or More Embodiments**

The novel biphasic or multiphasic pulse waveform is applicable for use with various medical devices including all defibrillator types: external (manual, semi-automated and fully
automated), wearable and implanted. In addition to defibrillators, the medical device may also be cardioverters and external/internal pacers, as well as other types of electrical stimulation medical devices, such as: neuro-stimulators, musculo-skeletal stimulators, organ stimulators and nerve/peripheral nerve stimulators, whether the devices are external or implantable. The biphasic or multiphasic waveform pulse may be particularly useful for any type of defibrillator and examples of the biphasic or multiphasic waveform pulse will be described in the context of a defibrillator for illustration purposes.

The novel biphasic or multiphasic waveform pulse is a distinctly different family of waveforms compared to the standard biphasic waveforms (see Figure 2) which has been used for the past several decades for defibrillators where the second phase's leading edge amplitude is the same as the first phase's trailing edge amplitude. The novel biphasic or multiphasic waveform pulse is also substantially different from the even higher energy dual capacitor biphasic waveform (see Figure 3) that was explored in the 1980s. The biphasic or multiphasic waveform pulse is a novel family of biphasic, or multiphasic, waveforms where the initial phase of the waveform is smaller in amplitude than the amplitude of the second phase of the waveform (see Figures 4A-7 for example). The typical circuitry used to generate the typical biphasic pulse shown in Figure 2 cannot be used to generate the biphasic or multiphasic waveform pulse described herein.

The novel biphasic or multiphasic waveform pulse allows for an efficacious pulse waveform to be delivered to the patient at a substantially lower level of total energy than ever before. In preclinical animal trials using the novel biphasic or multiphasic waveform pulse, successful defibrillation has been demonstrated using the novel biphasic or multiphasic waveform pulse, repeatedly, and at significantly lower levels of total delivered energy than the energy required by any current external defibrillators using either the original monophasic pulse or the now traditional biphasic pulse. For example, the novel biphasic or multiphasic waveform pulse may deliver 0.1 to 200 joules to a patient. Furthermore, the time for the waveform pulse delivery is between 1-20 ms and preferably 8-10 ms for the combined first and second phases of the waveform, although for triphasic and quadriphasic waveforms this is preferably in the 8-16 ms range for the entire waveform. For an embodiment in which the generated waveform is being
used for nerve stimulation or neuro-stimulation, the waveform period may be on the order of microseconds or shorter.

The novel biphasic or multiphasic waveform pulse also significantly reduces both the total energy and the current levels that must be discharged into the patient, thus reducing the chance of either skin burns or other damage to the skin, tissue or organs of the patient. The novel biphasic or multiphasic waveform pulse also reduces the maximum amount of energy that a device is required to store and deliver, and it increases the maximum lifespan of any battery powered device due to a more frugal use of the energy stored within it. The novel biphasic or multiphasic waveform pulse also enables the production of smaller devices as a lower total amount of energy is needed to be stored and delivered to the patient.

The novel biphasic or multiphasic waveform pulse is effective across a wide range of values for multiple variables/characteristics of the novel biphasic or multiphasic waveform pulse. For example, Figures 4A and 4B show a biphasic waveform with a first phase (being positive polarity in this example) and a second phase (being negative polarity in this example) with the amplitude of the first phase being small than the second phase. As shown in Figure 4B, a timing/duration of each phase (phase A and phase B) of the pulse waveform may be at least 1 millisecond for defibrillator medical devices and may be between 1-20 ms and an inter-phase period 400 between the first and second phases may be between 0 to 1500 microseconds. In addition, the first phase (that may be a positive polarity as shown in Figure 4B or a negative polarity) may have a rise time of the leading edge A and an amplitude of the leading edge A, a time of decay slope B and a phase tilt of the decay slope B, a fall time of trailing edge C and an amplitude of the trailing edge C. In addition, the second phase (that may be a negative polarity as shown in Figure 4B or a positive polarity, but is an opposite polarity of phase A) may have a rise time of leading edge D, an amplitude of the leading edge D, a time of decay slope E, a phase tilt of the decay slope E, a fall time of trailing edge F and an amplitude of the trailing edge F. The decay slope/tilt, for example, for each phase of the waveform may be between 0% and 95%. Each of the above characteristics of the pulse waveform may be adjusted and optimized depending on the exact therapeutic use to which the waveform is being put, as well as upon the nature and positioning of the device (external or implantable) and also upon the specifics of the patients themselves. Although a biphasic waveform is shown in Figure 4B, a multiphasic
waveform may have multiple phases (each phase with its own duration and amplitude) and multiple inter-phase periods. Each phase of the multiphasic waveform may have independent or the same adjustable rise time, slope time and fall time characteristics.

Figures 5 and 6 illustrate additional examples of a biphasic waveform. The example in Figure 5 of the waveform has a first positive polarity phase and a second negative polarity phase. The example in Figure 6 of the waveform has a first negative polarity phase and a second positive polarity phase. In the biphasic or multiphasic waveforms, the first phase has a polarity and then the second phase has an opposite polarity. Figure 7 illustrates an example of a multiphasic waveform that has a plurality of positive polarity phases (3 in this example) and a plurality of negative polarity phases (3 in this example). As with the other examples, the amplitude of the first phase is small than the amplitudes of the subsequent positive phases and the negative phases.

In an additional embodiment, the novel biphasic or multiphasic waveform pulse may have different phase tilts for either or both phases as shown in Figure 10. In addition, the novel biphasic or multiphasic waveform pulse may be generated and delivered to the patient in a lower energy manner, by only delivering portions of the pulse waveform to the patient. This can be done with the whole waveform (see Figure 11 and Figure 12) or else with individual phases of the waveform according to the energy conservation needs and the therapeutic needs. This can be accomplished via multiple means, including internal and external shunting of the current using high speed switching. In Figures 11-12, the novel biphasic or multiphasic waveform pulse may have a plurality of first phase pulses (with the same polarity) and then a plurality of second phase pulses that each have the same polarity, but opposite of the polarity of the first phase.

The novel biphasic or multiphasic waveform pulse may be generated in various manners. For example, as shown in Figure 1, a medical device 102 may have a biphasic or multiphasic waveform generator 104 and an energy source 106 that may be coupled to a control logic unit 108. The control logic unit may control the biphasic or multiphasic waveform generator 104 and the energy source 106 to generate the biphasic or multiphasic waveform pulse. One skilled in the art would understand that various circuitry for the biphasic or multiphasic waveform generator 104, the energy source 106 and the control logic unit 108 may be used to generate the biphasic or multiphasic waveform pulse. An example of circuitry that may be used to generate the biphasic
or multiphasic waveform pulse may be found in co-pending U.S. patent application number 14/661,949, filed on March 18, 2015, that is incorporated herein by reference.

While the foregoing has been with reference to a particular embodiment of the disclosure, it will be appreciated by those skilled in the art that changes in this embodiment may be made without departing from the principles and spirit of the disclosure, the scope of which is defined by the appended claims.
Claims:

1. A system for generating a therapeutic waveform, comprising:
   a pulse waveform generator that generates a waveform having at least one first phase and
   at least one second phase wherein the first phase of the waveform has an amplitude that is less
   than an amplitude of the second phase of the waveform.

2. The system of claim 1, wherein the waveform has a plurality of first phases and a
   plurality of second phases of a multiphasic waveform.

3. The system of claim 1, wherein the waveform has a single first phase and a single
   second phase of a biphasic waveform.

4. The system of claim 1, wherein the first phase has a first polarity and the second
   phase has a polarity that is opposite to the first polarity.

5. The system of claim 4, wherein the first phase has a positive polarity and the second
   phase has a negative polarity.

6. The system of claim 4, wherein the first phase has a negative polarity and the second
   phase has a positive polarity.

7. The system of claim 1, wherein each phase of the waveform has a duration of at
   least 1 millisecond.

8. The system of claim 7, wherein the waveform has an inter-phase period between
   the first phase and the second phase.

9. The system of claim 8, wherein the inter-phase period has a duration of between 0
   and 1500 microseconds.

10. The system of claim 1, wherein the first phase and second phase are rapidly
    switched so that only a fraction of the maximum possible energy for each phase is actually
    delivered through the patient at the time of delivery.

II. The system of claim 1, wherein each phase of the waveform has a decay tilt of
    between 0% and 95%.

12. A method for delivering a therapeutic pulse waveform, comprising:
    providing power to a pulse waveform generator;
    generating, by the pulse waveform generator, a waveform having at least one first phase
    and at least one second phase wherein the first phase has a polarity and the second phase has an
opposite polarity of the first phase and wherein the first phase of the waveform has an amplitude
that is less than an amplitude of the second phase of the waveform; and
controlling a duration and a shaping of each phase of the waveform.

13. The method of claim 12 further comprising controlling an inter-phase timing
between the first phase and the second phase.

14. The method of claim 12, wherein the waveform has a plurality of first phases and
a plurality of second phases of a multiphasic waveform.

15. The method of claim 12, wherein the waveform has a single first phase and a
single second phase of a biphasic waveform.

16. The method of claim 12, wherein the first phase of the waveform has a positive
polarity and the second phase has a negative polarity.

17. The method of claim 12, wherein the first phase has a negative polarity and the
second phase has a positive polarity.

18. The method of claim 12, wherein each phase of the waveform has a duration of at
least 1 millisecond.

19. The method of claim 13, wherein the inter-phase timing has a duration of between
0 and 1500 microseconds.

20. The method of claim 12, wherein generating the waveform further comprising
switching between the first phase and the second phase so that only a fraction of a maximum
possible energy for each phase is actually delivered through the patient.

21. The method of claim 12, wherein each phase of the waveform has a decay tilt of
between 0% and 95%.
