The present invention provides methods and compositions for treatment, screening, diagnosis and prognosis of cancer, such as prostate cancer, bladder cancer, breast cancer, esophagus cancer, head and neck cancer, colorectal cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer, uterus cancer and pancreatic cancer, for monitoring the effectiveness of cancer, such as prostate cancer, bladder cancer, breast cancer, esophagus cancer, head and neck cancer, colorectal cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer, uterus cancer and pancreatic cancer treatment, and for drug development.
INTRODUCTION

The present invention relates to the identification of a membrane protein associated with cancer, such as prostate cancer, bladder cancer, breast cancer, esophagus cancer, head and neck cancer, colorectal cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer, uterus cancer and/or pancreatic cancer which has utility as a therapeutic target for the treatment of cancers or as a marker for cancers. In particular, the protein represents a biological target against which affinity reagents including therapeutic antibodies, or other pharmaceutical agents, can be made. The invention also relates to the use of such affinity reagents for the treatment and/or diagnosis of cancers.

BACKGROUND OF THE INVENTION

The major challenges in treatment of cancer, such as prostate cancer, bladder cancer, breast cancer, esophagus cancer, head and neck cancer, colorectal cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer, uterus cancer and pancreatic cancer are to improve early detection rates, to find new non-invasive markers that can be used to follow disease progression and identify relapse, and to find improved and less toxic therapies, especially for more advanced disease where 5 year survival is still poor. There is a great need to identify targets which are more specific to the cancer cells, e.g. ones which are expressed on the surface of the tumour cells so that they can be attacked by promising new approaches like immunotherapeutics and targeted toxins.

Inactive N-acetylated-alpha-linked acidic dipeptidase-like protein 2 is a member of the peptidase M28 family. Protein expression of Inactive N-acetylated-alpha-linked acidic dipeptidase-like protein 2 on cancer cells, which would be required to demonstrate its utility as a cell-surface target for e.g. antibody-based cancer therapies, for example, has not previously been disclosed.

SUMMARY OF THE INVENTION

The present invention discloses the detection of Inactive N-acetylated-alpha-linked acidic dipeptidase-like protein 2, hereinafter referred to as NAALADL2, in membrane extracts of various disease tissues, e.g. prostate cancer, bladder cancer, breast cancer, esophagus cancer, head and neck cancer, colorectal cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer, uterus cancer and pancreatic cancer, hereinafter referred to as 'the diseases of the invention'.

The differential expression of NAALADL2 in various cancers permits the protein to be targeted using affinity reagent-, e.g. antibody-, based therapies for such cancers. Thus NAALADL2 can be used in the generation of affinity reagents, including antibodies, that bind specifically to epitopes within NAALADL2, and can be targeted by such affinity reagents as the basis of treatment. Affinity reagents, including antibodies, that target a protein on the cell surface of cancer cells may be employed in the treatment of cancer through a variety of mechanisms, including (i) lysis by complement mediated or antibody-dependent cellular cytotoxicity (ADCC), (ii) lysis by drugs or toxin(s) conjugated to such affinity reagents or (iii) inhibition of the physiological function of such protein, which may be driving growth of cancer cells, e.g. through signaling pathways. An important aspect of such affinity reagent-based treatment is that the normal expression profile of the protein target, in terms of tissue distribution and expression level, is such that any targeting of the...
protein target on normal tissues by the antibody does not give rise to adverse side-effects through binding to normal tissues.

The invention provides a method for the treatment or prophylaxis of cancer wherein NAALADL2 is expressed in said cancer, which comprises administering to a subject in need thereof a therapeutically effective amount of an affinity reagent which binds to NAALADL2.

The cancer is preferably one of the diseases of the invention.

The invention also provides an affinity reagent which binds to NAALADL2 for use in the treatment or prophylaxis of cancer, preferably wherein the cancer is one of the diseases of the invention.

The invention also provides the use of an affinity reagent which binds to NAALADL2 in the manufacture of a medicament for the treatment or prophylaxis of cancer, preferably wherein the cancer is one of the diseases of the invention.

The affinity reagents for use in the invention preferably bind specifically to NAALADL2. The affinity reagent may be an antibody, e.g. a whole antibody, or a functional fragment thereof or an antibody mimetic. Preferred affinity reagents included antibodies for example monoclonal antibodies.

The affinity reagent may be a chimeric antibody, a human antibody, a humanized antibody, a single chain antibody, a defucosylated antibody or a bispecific antibody.

Functional antibody fragments include is a UniBody, a domain antibody or a Nanobody.

Antibody mimetics include an Affibody, a DARPin, an Anticalin, an Avimer, a Versabody or a Duocalin.

The affinity reagents for use in the invention may contain or be conjugated to a therapeutic moiety, such as a cytotoxic moiety or a radioactive isotope. The affinity reagent may be an antibody drug conjugate or immunoconjugate.

The affinity reagent may elicit antibody-dependent cellular cytotoxicity (ADCC) or may elicit complement dependent cytotoxicity (CDC). The affinity reagent may induce apoptosis of cancer cells, kill or reduce the number of cancer stem cells and/or kill or reduce the number of circulating cancer cells. Affinity reagents may modulate a physiological function of NAALADL2, inhibit ligand binding to NAALADL2 and/or inhibit a signal transduction pathway mediated by NAALADL2.

In an alternative embodiment, the invention also provides a method for the treatment or prophylaxis of cancer wherein NAALADL2 is expressed in said cancer, which comprises administering to a subject in need thereof a therapeutically effective amount of a hybridizing agent capable of hybridizing to nucleic acid encoding NAALADL2.

The invention also provides a hybridizing agent capable of hybridizing to nucleic acid encoding NAALADL2 for use in the treatment or prophylaxis of a cancer, preferably wherein the cancer is one of the diseases of the invention.

The invention also provides the use of a hybridizing agent capable of hybridizing to nucleic acid encoding NAALADL2 in the manufacture of a medicament for the treatment or prophylaxis of a cancer, preferably wherein the cancer is one of the diseases of the invention.

The hybridizing agents for use in the invention preferably bind specifically to nucleic acid encoding one or more extracellular domains of NAALADL2.
Suitable hybridizing agents for use in the invention include inhibitory RNA, short interfering RNA (siRNA), short hairpin RNA (shRNA), microRNA (miRNA), anti-sense nucleic acid, complementary DNA (cDNA), oligonucleotides and ribozymes.

The invention also provides a method of detecting, diagnosing and/or screening for or monitoring the progression of a cancer wherein NAALADL2 is expressed in said cancer, or of monitoring the effect of a cancer drug or therapy wherein NAALADL2 is expressed in said cancer, in a subject which comprises detecting the presence or level of NAALADL2, or one or more fragments thereof, or the presence or level of nucleic acid encoding NAALADL2 or which comprises detecting a change in the level thereof in said subject.

Such a method may comprise detecting the presence of NAALADL2, or one or more fragments thereof, or the presence of nucleic acid encoding NAALADL2, in which either (a) the presence of an elevated level of NAALADL2 or said one or more fragments thereof or an elevated level of nucleic acid encoding NAALADL2 in the subject as compared with the level in a healthy subject, or (b) the presence of a detectable level of NAALADL2 or said one or more fragments thereof or a detectable level of nucleic acid encoding NAALADL2 in the subject as compared with a corresponding undetectable level in a healthy subject is indicative of the presence of the cancer wherein NAALADL2 is expressed in said cancer, in said subject.

The invention also provides a method of detecting, diagnosing and/or screening for or monitoring the progression a cancer wherein NAALADL2 is expressed in said cancer, or of monitoring the effect of a cancer drug or therapy wherein NAALADL2 is expressed in said cancer, in a subject which comprises detecting the presence or level of antibodies capable of immunospecific binding to NAALADL2, or one or more fragments thereof.

In the methods according to the invention, the presence of NAALADL2, or one or more fragments thereof, or the presence of nucleic acid encoding NAALADL2, or the presence or level of antibodies capable of immunospecific binding to NAALADL2, or one or more fragments thereof, may be detected by analysis of a biological sample obtained from the subject.

The presence of NAALADL2, or one or more fragments thereof, may be detected using an affinity reagent which binds to NAALADL2. The affinity reagent may be any suitable affinity reagent as mentioned herein. The affinity reagent may contain or be conjugated to a detectable label.

In any of the aspects of the invention referred to herein, the subject may be a human.

The invention also provides methods for identifying an agent for the treatment or prophylaxis of cancer wherein NAALADL2 is expressed in said cancer, wherein the method comprises (a) contacting NAALADL2, or one or more fragments thereof, with a candidate agent; and (b) determining whether the agent binds to NAALADL2, or one or more fragments thereof. The method may also further comprise the step of testing the ability of an agent which binds to NAALADL2, or one or more fragments thereof, to inhibit cancer wherein NAALADL2 is expressed in said cancer. The agent may, *inter alia*, modulate an activity of NAALADL2, reduce ligand binding to NAALADL2 or reduce NAALADL2 dimerisation.

In the various embodiments of the invention described herein, particular cancer types which may be mentioned are one of the diseases of the invention.

In one embodiment of the invention the cancer to be detected, prevented or treated is selected from prostate cancer, breast cancer, colorectal cancer, gastric cancer and pancreatic cancer.
In one embodiment the cancer to be detected, prevented or treated is prostate cancer.
In another embodiment the cancer to be detected, prevented or treated is bladder cancer.
In another embodiment the cancer to be detected, prevented or treated is breast cancer, e.g.
ER negative, PR negative and Her2 negative breast cancer, i.e. Triple negative breast cancer.
In another embodiment the cancer to be detected, prevented or treated is esophageal cancer.
In another embodiment the cancer to be detected, prevented or treated is head and neck cancer.
In another embodiment the cancer to be detected, prevented or treated is colorectal cancer.
In another embodiment the cancer to be detected, prevented or treated is liver cancer, e.g.
hepatocellular carcinoma.
In another embodiment the cancer to be detected, prevented or treated is lung cancer, e.g.
non-small cell lung cancer and/or small cell lung cancer.
In another embodiment the cancer to be detected, prevented or treated is ovarian cancer.
In another embodiment the cancer to be detected, prevented or treated is gastric cancer.
5
In another embodiment the cancer to be detected, prevented or treated is pancreatic cancer.
In another embodiment the cancer to be detected, prevented or treated is uterus cancer.
Other aspects of the present invention are set out below and in the claims herein.

BRIEF DESCRIPTION OF THE FIGURES

Figure 1 shows the specific lysis of LnCAP NAALADL2 expressing cells by activation of T cells by bispecific anti-NAALADL2-anti-CD3 polyclonal antibodies.

DETAILED DESCRIPTION OF THE INVENTION

The invention described in detail below encompasses the administration of therapeutic compositions to a subject, e.g. a mammalian subject, to treat or prevent cancer, e.g. the diseases of the invention. The invention also provides methods and compositions for clinical screening, diagnosis and prognosis of cancer, e.g. the diseases of the invention, in a mammalian subject for identifying patients most likely to respond to a particular therapeutic treatment, for monitoring the results of cancer e.g. the diseases of the invention therapy, for drug screening and drug development.

The invention is based on the finding that NAALADL2 protein is expressed in certain cancers. In particular, supporting data is enclosed herein which demonstrates the expression of NAALADL2 protein in the plasma membrane of prostate cancer, breast cancer, colorectal cancer, gastric cancer and pancreatic cancer. Immuno-histochemical analysis also shows strong staining of prostate cancer, colorectal cancer and breast cancer, with more moderate staining in esophagus cancer, head and neck cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer and uterus cancer. Therefore antibodies directed to NAALADL2 may have utility as therapeutics and diagnostics in these cancers and other cancer types showing expression of NAALADL2.

As used herein, the term "subject" refers to animal, preferably a mammal. The mammalian subject may be a non-human mammal, but is generally a human, such as a human adult.

The subject will in general be a living subject. However, whilst the uses, methods and compositions of the present invention are specially suited for screening, diagnosis and prognosis of a living subject, they may also be used for postmortem diagnosis in a subject, for example, to identify family members at risk of developing the same disease.
As used herein, the term "patient" refers to a subject who has or is suspected of having one or more of the diseases of the invention.

As used herein, the term "protein of the invention" refers to Inactive N-acetylated-alpha-linked acidic dipeptidase-like protein 2 (GenelID: 254827), which is referred to herein as NAALDL2. This protein has been found to be differentially expressed in various cancers thus providing a new target for affinity-based therapies of these cancers. A human sequence of the NAALDL2 protein is given in SEQ ID NO: 1. The term NAALDL2 (in the context of a protein) encompasses proteins whose amino acid sequences consist of or comprise the amino acid sequence given in SEQ ID NO: 1 or derivatives or variants thereof, particularly naturally-occurring human derivatives or variants thereof.

This protein has been identified in membrane protein extracts of cancer tissue samples from cancer patients through the methods and apparatus described in Example 1 (e.g. by liquid chromatography-mass spectrometry of membrane protein extracts). Peptide sequences were compared to the SWISS PROT and TrEMBL databases (held by the Swiss Institute of Bioinformatics (SIB) and the European Bioinformatics Institute (EBI) which are available at www.expasy.org), and the entry Q58DX5, Inactive N-acetylated-alpha-linked acidic dipeptidase-like protein 2 - NAALDL2, was identified. The nucleotide sequence encoding this protein is found at accession number NM_207015, as given in SEQ ID NO: 3.

According to SWISS-PROT, NAALDL2 is single-pass protein of the peptidase M28 family. The protein consists of one transmembrane region and has an extracellular tail of 653 amino acids between amino acids 143-795 of SEQ ID NO: 1 (SEQ ID NO: 19). NAALDL2 has previously been disclosed in WO2009028521 where siRNA targeting PIKB and NAALDL2 genes were used for inhibiting cellular growth of prostate cancer cells. The inventor has shown NAALDL2 expression by immunohistochemistry on the surface of cancer cells and not normal prostate cells, suggesting affinity-based therapies directed against the NAALDL2 protein (SEQ ID NOs: 1-2) in patients, including those with these cancers, will have a therapeutic effect.

Immuno-histochemical analysis also shows strong staining of prostate cancer, colorectal cancer and breast cancer, with more moderate staining in esophagus cancer, head and neck cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer and uterus cancer. The latter cancers are also preferred diseases of the invention.

NAALDL2 is useful as are fragments particularly epitope containing fragments e.g. antigenic or immunogenic fragments thereof and derivatives thereof, particularly fragments comprising extracellular domains (e.g. extracellular tails or loops) of the protein. Epitope containing fragments, including antigenic or immunogenic fragments, will typically be of length 12 amino acids or more, e.g. 20 amino acids or more, e.g. 50 or 100 amino acids or more. Fragments may be 95% or more of the length of the full protein, e.g. 90% or more, e.g. 75% or 50% or 25% or 10% or more of the length of the full protein.

Alternatively, the protein/polypeptide employed or referred to herein may be limited to those proteins/polypeptides specifically recited/described in the present specification or to a variant or derivative which has at least 80, 85, 90, 91, 92, 93, 94, 95, 96, 97, 98 or 99% amino acid sequence identity or similarity thereto. Percentage amino acid sequence identity/similarity may be determined by any suitable algorithm, e.g. BLAST, CLUSTAL, using appropriate default parameters.

Hence the term "NAALDL2" in the context of a protein or polypeptide refers to a protein
 whose amino acid sequence consists of or comprises the amino sequence given in any of SEQ ID NOs: 1-2 or a derivative or variant thereof which has at least 90% or 95% sequence identity to any of SEQ ID NOs: 1-2 and which protein has essentially the same tissue distribution as NAALADL2.

In the context of a nucleic acid, the term "NAALADL2" refers to a nucleic acid whose nucleotide sequence encodes a protein comprising the amino sequence given in any of SEQ ID NOs: 1-2 or a derivative or variant thereof which has at least 90% or 95% sequence identity to any of SEQ ID NOs: 1-2 and which protein has essentially the same tissue distribution as NAALADL2 protein.

The term "NAALADL2" in the context of a nucleic acid also refers to a nucleic acid whose nucleotide sequence comprises the sequence given in any of SEQ ID NOs: 3-4 or a derivative or variant thereof which has at least 90% or 95% sequence identity to any of SEQ ID NOs: 3-4 and which encodes a protein which has essentially the same tissue distribution as NAALADL2 protein.

Epitope-containing fragments of NAALADL2 including antigenic or immunogenic fragments will be capable of eliciting a relevant immune response in a patient. DNA encoding NAALADL2 is also useful as are fragments thereof, e.g. DNA encoding fragments of NAALADL2 such as immunogenic fragments thereof. Fragments of nucleic acid (e.g. DNA) encoding NAALADL2 may be 95% or more of the length of the full coding region, e.g. 90% or more e.g. 75% or 50% or 25% or 10% or more of the length of the full coding region. Fragments of nucleic acid (e.g. DNA) may be 36 nucleotides or more, e.g. 60 nucleotides or more, e.g. 150 or 300 nucleotides or more in length.

Derivatives of NAALADL2 include variants on the sequence in which one or more (e.g. 1-20 such as 15 amino acids, or up to 20% such as up to 10% or 5% or 1% by number of amino acids based on the total length of the protein) deletions, insertions or substitutions have been made. Substitutions may typically be conservative substitutions. Derivatives will typically have essentially the same biological function as the protein from which they are derived. Derivatives will typically be comparably antigenic or immunogenic to the protein from which they are derived. Derivatives will typically have either the ligand-binding activity, or the active receptor-complex forming ability, or preferably both, of the protein from which they are derived. Derivatives and variants will generally have the same tissue distribution as NAALADL2.

Derivatives of proteins also include chemically treated protein such as carboxymethylated, carboxyamidated, acetylated proteins, for example treated during purification.

In one aspect, the invention provides NAALADL2 or a composition comprising NAALADL2. The protein may be in isolated or purified form. The invention further provides a nucleic acid encoding NAALADL2 and a composition comprising a nucleic acid encoding NAALADL2.

In a further aspect, there is provided a composition capable of eliciting an immune response in a subject, which composition comprises a NAALADL2 polypeptide and/or one or more antigenic or immunogenic fragments thereof, and one or more suitable carriers, excipients, diluents or adjuvants (suitable adjuvants are discussed below).

The composition capable of eliciting an immune response may for example be provided as a vaccine comprising a NAALADL2 polypeptide or derivative or variant thereof, and/or one or more antigenic or immunogenic fragments thereof, optionally together with one or more suitable carriers, excipients, diluents or adjuvants.

In another aspect, the invention provides a NAALADL2 polypeptide, or one or more
fragments or derivatives or variants thereof, for the treatment or prophylaxis of e.g. one or more of
the diseases of the invention.

In another aspect, the invention provides a use of a NAALADL2 polypeptide, or one or
more fragments or derivatives or variants thereof, for the treatment or prophylaxis of e.g. one or
more of the diseases of the invention.

The invention also provides a use of a NAALADL2 polypeptide, one or more fragments or
derivatives or variants thereof, in the manufacture of a medicament for the treatment or prophylaxis
of e.g. one or more of the diseases of the invention.

In one aspect there is provided a method of treatment comprising administering a
therapeutically effective amount of a NAALADL2 polypeptide, one or more fragments or
derivatives or variants thereof, for the treatment or prophylaxis of e.g. one or more of the diseases
of the invention.

The invention further provides a method for the treatment or prophylaxis of e.g. the diseases
of the invention in a subject, or of vaccinating a subject against e.g. one or more of the diseases
of the invention, which comprises the step of administering to the subject an effective amount of a
NAALADL2 polypeptide and/or one or more antigenic or immunogenic fragments or derivatives or
variants thereof, for example as a vaccine.

In another aspect, the invention provides methods of treating e.g. the diseases of the
invention, comprising administering to a patient a therapeutically effective amount of a compound
that modulates (e.g. upregulates or downregulates) or complements the expression or the biological
activity (or both) of NAALADL2 in patients having e.g. the diseases of the invention, in order to (a)
prevent the onset or development of e.g. the diseases of the invention; (b) prevent the progression of
e.g. the diseases of the invention; or (c) ameliorate the symptoms of e.g. the diseases of the
invention.

In yet a further embodiment, the invention provides a medicament comprising, separately or
together:

(a) NAALADL2, and
(b) an anti-cancer agent,
for simultaneous, sequential or separate administration in the treatment of cancer, preferably
in the treatment of one of the diseases of the invention.

NAALADL2 can be used for detection, prognosis, diagnosis, or monitoring of, e.g. the
diseases of the invention or for drug development.

According to another aspect of the invention, we provide a method of detecting, diagnosing
and/or screening for or monitoring the progression of e.g. the diseases of the invention or of
monitoring the effect of e.g. an anti-cancer drug or therapy directed towards the diseases of the
invention in a subject which comprises detecting the presence or level of NAALADL2, or one or
more fragments thereof, or the presence or level of nucleic acid encoding NAALADL2 or the
presence or level of the activity of NAALADL2 or which comprises detecting a change in the level
thereof in said subject.

According to another aspect of the invention we provide a method of detecting, diagnosing
and/or screening for e.g. the diseases of the invention in a candidate subject which comprises
detecting the presence of NAALADL2, or one or more fragments thereof, or the presence of nucleic
acid encoding NAALADL2 or the presence of the activity of NAALADL2 in said candidate subject,
in which either (a) the presence of an elevated level of NAALADL2 or said one or more fragments thereof or an elevated level of nucleic acid encoding NAALADL2 or the presence of an elevated level of NAALADL2 activity in the candidate subject as compared with the level in a healthy subject or (b) the presence of a detectable level of NAALADL2 or said one or more fragments thereof or a detectable level of nucleic acid encoding NAALADL2 or the presence of a detectable level of NAALADL2 activity in the candidate subject as compared with a corresponding undetectable level in a healthy subject indicates the presence of e.g. the diseases of the invention in said subject.

According to another aspect of the invention, we provide a method of monitoring the progression of e.g. the diseases of the invention in a subject or of monitoring the effect of e.g. an anti-cancer drug or therapy directed towards the diseases of the invention which comprises detecting the presence of NAALADL2, or one or more fragments thereof, or the presence of nucleic acid encoding NAALADL2 or the presence of the activity of NAALADL2 in said candidate subject at a first time point and at a later time point, the presence of an elevated or lowered level of NAALADL2 or said one or more fragments thereof or an elevated or lowered level of nucleic acid encoding NAALADL2 or the presence of an elevated or lowered level of NAALADL2 activity in the subject at the later time point as compared with the level in the subject at said first time point, indicating the progression or regression of e.g. the diseases of the invention or indicating the effect or non-effect of e.g. an anti-cancer drug or therapy directed towards the diseases of the invention in said subject.

For NAALADL2, the detected level obtained upon analyzing tissue sample from subjects having e.g. the diseases of the invention relative to the detected level obtained upon analyzing tissue from subjects free from e.g. the diseases of the invention will depend upon the particular analytical protocol and detection technique that is used. Accordingly, the present invention contemplates that each laboratory will establish a reference range in subjects free from e.g. the diseases of the invention according to the analytical protocol and detection technique in use, as is conventional in the diagnostic art. Preferably, at least one control positive tissue sample from a subject known to have e.g. the diseases of the invention or at least one control negative tissue sample from a subject known to be free from e.g. the diseases of the invention (and more preferably both positive and negative control samples) are included in each batch of test samples analysed.

In one aspect of the invention, liquid chromatography-mass spectrometry analysis or other appropriate methods are used to analyze the diseases of the invention tissue samples from a subject, preferably a living subject, in order to measure the expression of NAALADL2 for screening or diagnosis of e.g. the diseases of the invention, to determine the prognosis of a the diseases of the invention patient, to monitor the effectiveness of the diseases of the invention therapy, or for drug development.

In any of the above methods, the level that may be detected in the candidate subject who has cancer, e.g. the diseases of the invention is preferably 2 or more fold higher than the level in the healthy subject.

In one embodiment of the invention, tissue sample from a subject (e.g. a subject suspected of having the diseases of the invention) is analysed by liquid chromatography-mass spectrometry for detection of NAALADL2. An increased abundance of NAALADL2 in the tissue from the subject relative to tissue from a subject or subjects free from the diseases of the invention (e.g. a control
sample) or a previously determined reference range indicates the presence of the diseases of the invention.

In relation to fragments, epitope containing fragments, immunogenic fragments or antigenic fragments of NAALADL2:

for the relevant cancer applications, in one aspect of the invention these comprise the sequence identified as a tryptic sequence in Example 1.

As used herein, NAALADL2 is "isolated" when it is present in a preparation that is substantially free of contaminating proteins, i.e. a preparation in which less than 10% (for example less than 5%, such as less than 1%) of the total protein present is contaminating protein(s). A contaminating protein is a protein having a significantly different amino acid sequence from that of isolated NAALADL2, as determined by mass spectral analysis. As used herein, a "significantly different" sequence is one that permits the contaminating protein to be resolved from NAALADL2 by mass spectral analysis, performed according to the protocol described herein in Example 1.

In the diagnostic and prognostic methods of the invention, NAALADL2 can be assayed by any method known to those skilled in the art, including but not limited to, the Preferred Technologies described herein, kinase assays, enzyme assays, binding assays and other functional assays, immunoassays, and western blotting.

Alternatively, NAALADL2 can be detected in an immunoassay. In one embodiment, an immunoassay is performed by contacting a sample from a subject to be tested with an anti-NAALADL2 antibody (or other affinity reagent) under conditions such that binding (e.g. immunospecific binding) can occur if NAALADL2 is present, and detecting or measuring the amount of any binding (e.g. immunospecific binding) by the agent. NAALADL2 binding agents can be produced by the methods and techniques taught herein. In a particular embodiment, NAALADL2 is analysed using immunohistochemistry.

NAALADL2 may be detected by virtue of the detection of a fragment thereof e.g. an epitope containing (e.g. an immunogenic or antigenic) fragment thereof. Fragments may have a length of at least 10, more typically at least 20 amino acids e.g. at least 50 or 100 amino acids e.g. at least 150 or 200 amino acids; e.g. at least 300 or 500 amino acids; e.g. at least 700 or 900 amino acids.

In one embodiment, binding of an affinity reagent (e.g. an antibody) in tissue sections can be used to detect aberrant NAALADL2 localization or an aberrant level of NAALADL2. In a specific embodiment, an antibody (or other affinity reagent) to NAALADL2 can be used to assay a patient tissue (e.g. a prostate, bladder, breast, esophagus, head and neck, colorectal, liver, lung, ovarian, gastric, uterus and pancreatic tissue) for the level of NAALADL2 where an aberrant level of NAALADL2 is indicative of the diseases of the invention. As used herein, an "aberrant level" means a level that is increased compared with the level in a subject free from the diseases of the invention or a reference level.

Any suitable immunoassay can be used, including, without limitation, competitive and non-competitive assay systems using techniques such as western blots, radioimmunoassays, ELISA (enzyme linked immunosorbent assay), "sandwich" immunoassays, immunoprecipitation assays, precipitin reactions, gel diffusion precipitin reactions, immunodiffusion assays, agglutination assays, complement-fixation assays, immunoradiometric assays, fluorescent immunoassays and protein A immunoassays.

For example, NAALADL2 can be detected in a fluid sample (e.g. blood, urine, or saliva) by
means of a two-step sandwich assay. In the first step, a capture reagent (e.g. an anti-NAALADL2 antibody or other affinity reagent) is used to capture NAALADL2. The capture reagent can optionally be immobilized on a solid phase. In the second step, a directly or indirectly labeled detection reagent is used to detect the captured NAALADL2. In one embodiment, the detection reagent is a lectin. Any lectin can be used for this purpose that preferentially binds to NAALADL2 rather than to other isoforms that have the same core protein as NAALADL2 or to other proteins that share the antigenic determinant recognized by the antibody. In a preferred embodiment, the chosen lectin binds NAALADL2 with at least 2-fold greater affinity, more preferably at least 5-fold greater affinity, still more preferably at least 10-fold greater affinity, than to said other isoforms that have the same core protein as NAALADL2 or to said other proteins that share the antigenic determinant recognized by the affinity reagent. Based on the present description, a lectin that is suitable for detecting NAALADL2 can readily be identified by methods well known in the art, for instance upon testing one or more lectins enumerated in Table 1 on pages 158-159 of Sumar et al., Lectins as Indicators of Disease-Associated Glycoforms, In: Gabius H-J & Gabius S (eds.), 1993, Lectins and Glyobiology, at pp. 158-174 (which is incorporated herein by reference in its entirety). In an alternative embodiment, the detection reagent is an antibody (or other affinity reagent), e.g. an antibody that specifically (e.g. immunospecifically) detects other post-translational modifications, such as an antibody that immunospecifically binds to phosphorylated amino acids. Examples of such antibodies include those that bind to phosphotyrosine (BD Transduction Laboratories, catalog nos.: P11230-050/P11230-150; P111120; P38820; P39020), those that bind to phosphoserine (Zymed Laboratories Inc., South San Francisco, CA, catalog no. 61-8100) and those that bind to phosphothreonine (Zymed Laboratories Inc., South San Francisco, CA, catalogue nos. 71-8200, 13-9200).

If desired, a gene encoding NAALADL2, a related gene, or related nucleic acid sequences or subsequences, including complementary sequences, can also be used in hybridization assays. A nucleotide encoding NAALADL2, or subsequences thereof comprising at least 8 nucleotides, preferably at least 12 nucleotides, and most preferably at least 15 nucleotides can be used as a hybridization probe. Hybridization assays can be used for detection, prognosis, diagnosis, or monitoring of conditions, disorders, or disease states, associated with aberrant expression of the gene encoding NAALADL2, or for differential diagnosis of subjects with signs or symptoms suggestive of e.g. the diseases of the invention. In particular, such a hybridization assay can be carried out by a method comprising contacting a subject's sample containing nucleic acid with a nucleic acid probe capable of hybridizing to a DNA or RNA that encodes NAALADL2, under conditions such that hybridization can occur, and detecting or measuring any resulting hybridization.

Hence nucleic acid encoding NAALADL2 (e.g. DNA or more suitably RNA) may be detected, for example, using a hybridizing agent (particularly an oligonucleotide probe) capable of hybridizing to nucleic acid encoding NAALADL2.

One such exemplary method comprises:

- contacting one or more oligonucleotide probes comprising 10 or more consecutive nucleotides complementary to a nucleotide sequence encoding NAALADL2, with an RNA obtained from a biological sample from the subject or with cDNA copied from the RNA, wherein said contacting occurs under conditions that permit hybridization of the probe to the nucleotide sequence if present;
- detecting hybridization, if any, between the probe and the nucleotide sequence; and
comparing the hybridization, if any, detected in step (b) with the hybridization detected in a
control sample, or with a previously determined reference range.

The invention also provides diagnostic kits, comprising an anti-NAALADL2 antibody (or
other affinity reagent). In addition, such a kit may optionally comprise one or more of the
following:

1. instructions for using the anti-NAALADL2 affinity reagent for diagnosis, prognosis,
   therapeutic monitoring or any combination of these applications;
2. a labeled binding partner to the affinity reagent;
3. a solid phase (such as a reagent strip) upon which the anti-NAALADL2 affinity reagent
   is immobilized; and
4. a label or insert indicating regulatory approval for diagnostic, prognostic or therapeutic
   use or any combination thereof. If no labeled binding partner to the affinity reagent is provided, the
   anti-NAALADL2 affinity reagent itself can be labeled with a detectable marker, e.g. a
   chemiluminescent, enzymatic, fluorescent, or radioactive moiety.

The invention also provides a kit comprising a nucleic acid probe capable of hybridizing to
nucleic acid, suitably RNA, encoding NAALADL2. In a specific embodiment, a kit comprises one
or more containers a pair of primers (e.g. each in the size range of 6-30 nucleotides, more preferably
10-30 nucleotides and still more preferably 10-20 nucleotides) that under appropriate reaction
conditions can prime amplification of at least a portion of a nucleic acid encoding NAALADL2,
such as by polymerase chain reaction (see, e.g. Innis et al., 1990, PCR Protocols, Academic Press,
Inc., San Diego, CA), ligase chain reaction (see EP 320,308) use of Qβ replicase, cyclic probe
reaction, or other methods known in the art.

A kit can optionally further comprise a predetermined amount of NAALADL2 or a nucleic
acid encoding NAALADL2, e.g. for use as a standard or control.

As used herein, the term "sample" includes a bodily fluid (e.g. blood, urine or saliva) and
tissue biopsies taken from a subject at risk of having one or more of the diseases of the invention
(e.g. a biopsy such as a prostate, bladder, breast, esophagus, head and neck, colorectal, liver, lung,
oviduct, gastric, uterus and pancreatic biopsy) or homogenate thereof.

For example, the biological sample used can be from any source such as a serum sample or a
tissue sample e.g. prostate, bladder, breast, esophagus, head and neck, colorectal, liver, lung,
oviduct, gastric, uterus and pancreatic tissue. For instance, when looking for evidence of metastatic
diseases of the invention, one would look at major sites of the diseases of the invention
metastasis, e.g. the bones, bladder, rectum for prostate cancer, the bones, lungs, skin and the liver for
bladder cancer, the bones, liver and lungs for breast cancer, the liver, peritoneal cavity, pelvis,
retroperitoneum and lungs for colorectal cancer, the lungs, bones, liver and skin for head and neck
cancer, the lungs and bone for liver cancer, the brain, liver, bones and adrenal glands for lung
cancer, the liver for pancreatic cancer, the abdomen for ovarian cancer, the liver, lungs and bones for
esophageal cancer, the bladder, rectum, lungs and bones for uterine cancer and the liver, lungs,
brain, bones, kidneys and pancreas for gastric cancer.

Alternatively the presence of NAALADL2, or one or more fragments thereof, or the
presence of nucleic acid encoding NAALADL2 or the presence of the activity of NAALADL2 may
be detected by analysis in situ.

In certain embodiments, methods of diagnosis described herein may be at least partly, or
wholly, performed in vitro or ex vivo.

Suitably the presence of NAALADL2, or one or more fragments thereof, or the presence of nucleic acid encoding NAALADL2 or the presence of the activity of NAALADL2 is detected quantitatively.

For example, quantitatively detecting may comprise:
contacting a biological sample with an affinity reagent that is specific for NAALADL2, said affinity reagent optionally being conjugated to a detectable label; and

detecting whether binding has occurred between the affinity reagent and at least one species in the sample, said detection being performed either directly or indirectly.

Alternatively the presence of NAALADL2, or one or more fragments thereof, or the presence of nucleic acid encoding NAALADL2 or the presence of the activity of NAALADL2 may be detected quantitatively by means involving use of an imaging technology.

In another embodiment, the method of the invention involves use of immunohistochemistry on e.g. prostate, bladder, breast, esophagus, head and neck, colorectal, liver, lung, ovarian, gastric, uterus and pancreatic tissue sections in order to determine the presence of NAALADL2, or one or more fragments thereof, or the presence of nucleic acid encoding NAALADL2 or the presence of the activity of NAALADL2, and thereby to localise e.g. the diseases of the invention cells.

In one embodiment the presence of NAALADL2 or one or more epitope-containing fragments thereof is detected, for example using an affinity reagent capable of specific binding to NAALADL2 or one or more fragments thereof, such as an antibody.

In another embodiment the activity of NAALADL2 is detected.

Use in Clinical Studies

The diagnostic methods and compositions of the present invention can assist in monitoring a clinical study, e.g. to evaluate drugs for therapy of the diseases of the invention. In one embodiment, candidate molecules are tested for their ability to restore NAALADL2 levels in a subject having e.g. the diseases of the invention to levels found in subjects free from the diseases of the invention or, in a treated subject, to preserve NAALADL2 levels at or near non-prostate cancer, non-bladder cancer, non-breast cancer, non-esophagus cancer, non-head and neck cancer, non-colorectal cancer, non-liver cancer, non-lung cancer, non-ovarian cancer, non-gastric cancer, non-uterus cancer or non-pancreatic cancer values.

In another embodiment, the methods and compositions of the present invention are used to screen candidates for a clinical study to identify individuals having e.g. the diseases of the invention; such individuals can then be excluded from the study or can be placed in a separate cohort for treatment or analysis.

Production of Protein of the Invention and Corresponding Nucleic Acid

In one aspect the invention provides a method of treating or preventing e.g. the diseases of the invention, comprising administering to a subject in need of such treatment or prevention a therapeutically effective amount of nucleic acid encoding NAALADL2 or one or more fragments or derivatives thereof, for example in the form of a vaccine.

In another aspect there is provided a method of treating or preventing e.g. the diseases of the invention comprising administering to a subject in need of such treatment or prevention a therapeutically effective amount of nucleic acid that inhibits the function or expression of NAALADL2.
The methods (and/or other DNA aspects disclosed herein) of the invention may, for example include wherein the nucleic acid is a NAALADL2 anti-sense nucleic acid or ribozyme.

Thus the invention includes the use of nucleic acid encoding NAALADL2 or one or more fragments or derivatives thereof, in the manufacture of a medicament for treating or preventing e.g. the diseases of the invention.

There is also provided the use of nucleic acid that inhibits the function or expression of NAALADL2 in the manufacture of a medicament for treating or preventing e.g. one or more of the diseases of the invention.

A DNA employed in the present invention can be obtained by isolation as a cDNA fragment from cDNA libraries using as starter materials commercial mRNAs and determining and identifying the nucleotide sequences thereof. That is, specifically, clones are randomly isolated from cDNA libraries, which are prepared according to Ohara et al.'s method (DNA Research Vol.4, 53-59 (1997)). Next, through hybridization, duplicated clones (which appear repeatedly) are removed and then in vitro transcription and translation are carried out. Nucleotide sequences of both termini of clones, for which products of 50 kDa or more are confirmed, are determined.

Furthermore, databases of known genes are searched for homology using the thus obtained terminal nucleotide sequences as queries.

In addition to the above screening method, the 5' and 3' terminal sequences of cDNA are related to a human genome sequence. Then an unknown long-chain gene is confirmed in a region between the sequences, and the full-length of the cDNA is analyzed. In this way, an unknown gene that is unable to be obtained by a conventional cloning method that depends on known genes can be systematically cloned.

Moreover, all of the regions of a human-derived gene containing a DNA of the present invention can also be prepared using a PCR method such as RACE while paying sufficient attention to prevent artificial errors from taking place in short fragments or obtained sequences. As described above, clones having DNA of the present invention can be obtained.

In another means for cloning DNA of the present invention, a synthetic DNA primer having an appropriate nucleotide sequence of a portion of a polypeptide of the present invention is produced, followed by amplification by the PCR method using an appropriate library. Alternatively, selection can be carried out by hybridization of the DNA of the present invention with a DNA that has been incorporated into an appropriate vector and labeled with a DNA fragment or a synthetic DNA encoding some or all of the regions of the polypeptide of the present invention. Hybridization can be carried out by, for example, the method described in Current Protocols in Molecular Biology (edited by Frederick M. Ausubel et al., 1987). DNA of the present invention may be any DNA, as long as they contain nucleotide sequences encoding the polypeptides of the present invention as described above. Such a DNA may be a cDNA identified and isolated from cDNA libraries or the like that are derived from prostate, bladder, breast, esophagus, head and neck, colorectal, liver, lung, ovarian, gastric, uterus and pancreatic tissue. Such a DNA may also be a synthetic DNA or the like. Vectors for use in library construction may be any of bacteriophages, plasmids, cosmids, phargemids, or the like. Furthermore, by the use of a total RNA fraction or a mRNA fraction prepared from the above cells and/or tissues, amplification can be carried out by a direct reverse transcription coupled polymerase chain reaction (hereinafter abbreviated as "RT-PCR method").

DNA encoding the above polypeptide consisting of an amino acid sequence that is
substantially identical to the amino acid sequence of NAALADL2 or DNA encoding the above polypeptide consisting of an amino acid sequence derived from the amino acid sequence of NAALADL2 by deletion, substitution, or addition of one or more amino acids composing a portion of the amino acid sequence can be easily produced by an appropriate combination of, for example, a site-directed mutagenesis method, a gene homologous recombination method, a primer elongation method, and the PCR method known by persons skilled in the art. In addition, at this time, a possible method for causing a polypeptide to have substantially equivalent biological activity is substitution of homologous amino acids (e.g. polar and nonpolar amino acids, hydrophobic and hydrophilic amino acids, positively-charged and negatively charged amino acids, and aromatic amino acids) among amino acids composing the polypeptide. Furthermore, to maintain substantially equivalent biological activity, amino acids within functional domains contained in the polypeptide of the present invention are preferably conserved.

Furthermore, examples of DNA of the present invention include DNA comprising a nucleotide sequence that encodes the amino acid sequence of NAALADL2 and DNA hybridizing under stringent conditions to the DNA and encoding a polypeptide (protein) having biological activity (function) equivalent to the function of the polypeptide consisting of the amino acid sequence of NAALADL2. Under such conditions, an example of such DNA capable of hybridizing to DNA comprising the nucleotide sequence that encodes the amino acid sequence of NAALADL2 is DNA comprising a nucleotide sequence that has a degree of overall mean homology with the entire nucleotide sequence of the DNA, such as approximately 80% or more, preferably approximately 90% or more, and more preferably approximately 95% or more. Hybridization can be carried out according to a method known in the art such as a method described in Current Protocols in Molecular Biology (edited by Frederick M. Ausubel et al., 1987) or a method according thereto. Here, "stringent conditions" are, for example, conditions of approximately "1*SSC, 0.1% SDS, and 37°C", more stringent conditions of approximately "0.5*SSC, 0.1% SDS, and 42°C", or even more stringent conditions of approximately "0.2*SSC, 0.1% SDS, and 65°C". With more stringent hybridization conditions, the isolation of a DNA having high homology with a probe sequence can be expected. The above combinations of SSC, SDS, and temperature conditions are given for illustrative purposes. Stringency similar to the above can be achieved by persons skilled in the art using an appropriate combination of the above factors or other factors (for example, probe concentration, probe length, and reaction time for hybridization) for determination of hybridization stringency.

A cloned DNA of the present invention can be directly used or used, if desired, after digestion with a restriction enzyme or addition of a linker, depending on purposes. The DNA may have ATG as a translation initiation codon at the 5' terminal side and have TAA, TGA, or TAG as a translation termination codon at the 3' terminal side. These translation initiation and translation termination codons can also be added using an appropriate synthetic DNA adapter.

In the methods/uses of the invention, NAALADL2 may for example be provided in isolated form, such as where the NAALADL2 polypeptide has been purified to at least to some extent. NAALADL2 polypeptide may be provided in substantially pure form, that is to say free, to a substantial extent, from other proteins. NAALADL2 polypeptide can also be produced using recombinant methods, synthetically produced or produced by a combination of these methods. NAALADL2 can be easily prepared by any method known by persons skilled in the art, which
involves producing an expression vector containing appropriate DNA of the present invention or a
gene containing a DNA of the present invention, culturing a transformant transformed using the
expression vector, generating and accumulating a relevant polypeptide of the present invention or a
recombinant protein containing the polypeptide, and then collecting the resultant.

Recombinant NAALADL2 polypeptide may be prepared by processes well known in the art
from genetically engineered host cells comprising expression systems. Accordingly, the present
invention also relates to expression systems which comprise a NAALADL2 polypeptide or nucleic
acid, to host cells which are genetically engineered with such expression systems and to the
production of NAALADL2 polypeptide by recombinant techniques. For recombinant NAALADL2
polypeptide production, host cells can be genetically engineered to incorporate expression systems
or portions thereof for nucleic acids. Such incorporation can be performed using methods well
known in the art, such as, calcium phosphate transfection, DEAD-dextran mediated transfection,
transvection, microinjection, cationic lipid-mediated transfection, electroporation, transduction,
scape loading, ballistic introduction or infection (see e.g. Davis et al., Basic Methods in Molecular

As host cells, for example, bacteria of the genus Escherichia, Streptococci, Staphylococci,
Streptomyces, bacteria of the genus Bacillus, yeast, Aspergillus cells, insect cells, insects, and animal
cells are used. Specific examples of bacteria of the genus Escherichia, which are used herein,
(Nucleic Acids Research, Vol. 9, 309 (1981)), JA221 (Journal of Molecular Biology, Vol. 120, 517
(1978)), and HB101 (Journal of Molecular Biology, Vol. 41, 459 (1969)). As bacteria of the genus
Bacillus, for example, Bacillus subtilis Mil 14 (Gene, Vol. 24, 255 (1983)) and 207-21 (Journal of
Biochemistry, Vol. 95, 87 (1984)) are used. As yeast, for example, Saccaromyces cerevisiae AH22,
AH22R-, NA87-1 1A, DKD-5D, and 20B-12, Schizosaccharomyces pombe NCYC1913 and
NCYC2036, and Pichia pastoris are used. As insect cells, for example, Drosophila S2 and
Spodoptera SF9 cells are used. As animal cells, for example, COS-7 and Vero monkey cells, CHO
Chinese hamster cells (hereinafter abbreviated as CHO cells), dhfr-gene-deficient CHO cells, mouse
L cells, mouse AtT-20 cells, mouse myeloma cells, rat GH3 cells, human FL cells, COS, HeLa,
C127,3T3, HEK 293, BHK and Bowes melanoma cells are used.

Cell-free translation systems can also be employed to produce recombinant polypeptides
(e.g. rabbit reticulocyte lysate, wheat germ lysate, SP6/T7 in vitro T&T and RTS 100 E. Coli HY
transcription and translation kits from Roche Diagnostics Ltd., Lewes, UK and the TNT Quick
coupled Transcription/Translation System from Promega UK, Southampton, UK).

The expression vector can be produced according to a method known in the art. For
example, the vector can be produced by (1) excising a DNA fragment containing a DNA of the
present invention or a gene containing a DNA of the present invention and (2) ligating the DNA
fragment downstream of the promoter in an appropriate expression vector. A wide variety of
expression systems can be used, such as and without limitation, chromosomal, episomal and virus-
derived systems, e.g. plasmids derived from Escherichia coli (e.g. pBR322, pBR325, pUC18, and
pUC1 18), plasmids derived from Bacillus subtilis (e.g. pUBL 10, pTP5, and pC194), from
bacteriophage, from transposons, from yeast episomes (e.g. pSH19 and pSH15), from insertion
elements, from yeast chromosomal elements, from viruses such as baculoviruses, papova viruses
such as SV40, vaccinia viruses, adenoviruses, fowl pox viruses, pseudorabies viruses and retroviruses, and vectors derived from combinations thereof, such as those derived from plasmid and bacteriophage (such as [lambda] phage) genetic elements, such as cosmids and phagemids. The expression systems may contain control regions that regulate as well as engender expression.

Promoters to be used in the present invention may be any promoters as long as they are appropriate for hosts to be used for gene expression. For example, when a host is *Escherichia coli*, a trp promoter, a lac promoter, a recA promoter, a pL promoter, an lpp promoter, and the like are preferred. When a host is *Bacillus subtilis*, an SOI promoter, an SP02 promoter, a penP promoter, and the like are preferred. When a host is yeast, a PH05 promoter, a PGK promoter, a GAP promoter, an ADH promoter, and the like are preferred. When an animal cell is used as a host, examples of promoters for use in this case include an SRa promoter, an SV40 promoter, an LTR promoter, a CMV promoter, and an HSV-TK promoter. Generally, any system or vector that is able to maintain, propagate or express a nucleic acid to produce a polypeptide in a host may be used.

The appropriate nucleic acid sequence may be inserted into an expression system by any variety of well known and routine techniques, such as those set forth in Sambrook *et al.*, supra. Appropriate secretion signals may be incorporated into the NAALADL2 polypeptide to allow secretion of the translated protein into the lumen of the endoplasmic reticulum, the periplasmic space or the extracellular environment. These signals may be endogenous to the NAALADL2 polypeptide or they may be heterologous signals. Transformation of the host cells can be carried out according to methods known in the art. For example, the following documents can be referred to: *Proc. Natl. Acad. Sci. U.S.A.*, Vol. 69, 2110 (1972); *Gene*, Vol. 17, 107 (1982); *Molecular & General Genetics*, Vol. 168, 111 (1979); *Methods in Enzymology*, Vol. 194, 182-187 (1991); *Proc. Natl. Acad. Sci. U.S.A.*), Vol. 75, 1929 (1978); Cell Technology, separate volume 8, New Cell Technology, Experimental Protocol. 263-267 (1995) (issued by Shujunsha); and *Virology*, Vol. 52, 456 (1973). The thus obtained transformant transformed with an expression vector containing a DNA of the present invention or a gene containing a DNA of the present invention can be cultured according to a method known in the art. For example, when hosts are bacteria of the genus *Escherichia*, the bacteria are generally cultured at approximately 15°C to 43°C for approximately 3 to 24 h. If necessary, aeration or agitation can also be added. When hosts are bacteria of the genus *Bacillus*, the bacteria are generally cultured at approximately 30°C to 40°C for approximately 6 to 24 h. If necessary, aeration or agitation can also be added. When transformants whose hosts are yeast are cultured, culture is generally carried out at approximately 20°C to 35°C for approximately 24 to 72 h using media with pH adjusted to be approximately 5 to 8. If necessary, aeration or agitation can also be added. When transformants whose hosts are animal cells are cultured, the cells are generally cultured at approximately 30°C to 40°C for approximately 15 to 60 h using media with the pH adjusted to be approximately 6 to 8. If necessary, aeration or agitation can also be added.

If a NAALADL2 polypeptide is to be expressed for use in cell-based screening assays, it is preferred that the polypeptide be produced at the cell surface. In this event, the cells may be harvested prior to use in the screening assay. If the NAALADL2 polypeptide is secreted into the medium, the medium can be recovered in order to isolate said polypeptide. If produced intracellularly, the cells must first be lysed before the NAALADL2 polypeptide is recovered.

NAALADL2 polypeptide can be recovered and purified from recombinant cell cultures or from other biological sources by well known methods including, ammonium sulphate or ethanol.
precipitation, acid extraction, anion or cation exchange chromatography, phosphocellulose chromatography, affinity chromatography, hydroxylapatite chromatography, molecular sieving chromatography, centrifugation methods, electrophoresis methods and lectin chromatography. In one embodiment, a combination of these methods is used. In another embodiment, high performance liquid chromatography is used. In a further embodiment, an antibody which specifically binds to a NAALADL2 polypeptide can be used to deplete a sample comprising a NAALADL2 polypeptide of said polypeptide or to purify said polypeptide.

To separate and purify a polypeptide or a protein of the present invention from the culture products, for example, after culture, microbial bodies or cells are collected by a known method, they are suspended in an appropriate buffer, the microbial bodies or the cells are disrupted by, for example, ultrasonic waves, lysozymes, and/or freeze-thawing, the resultant is then subjected to centrifugation or filtration, and then a crude extract of the protein can be obtained. The buffer may also contain a protein denaturation agent such as urea or guanidine hydrochloride or a surfactant such as Triton X-100(TM). When the protein is secreted in a culture solution, microbial bodies or cells and a supernatant are separated by a known method after the completion of culture and then the supernatant is collected. The protein contained in the thus obtained culture supernatant or the extract can be purified by an appropriate combination of known separation and purification methods. The thus obtained polypeptide (protein) of the present invention can be converted into a salt by a known method or a method according thereto. Conversely, when the polypeptide (protein) of the present invention is obtained in the form of a salt, it can be converted into a free protein or peptide or another salt by a known method or a method according thereto. Moreover, an appropriate protein modification enzyme such as trypsin or chymotrypsin is caused to act on a protein produced by a recombinant before or after purification, so that modification can be arbitrarily added or a polypeptide can be partially removed. The presence of a polypeptide (protein) of the present invention or a salt thereof can be measured by various binding assays, enzyme immunoassays using specific antibodies, and the like.

Techniques well known in the art may be used for refolding to regenerate native or active conformations of the NAALADL2 polypeptide when the polypeptide has been denatured during isolation and or purification. In the context of the present invention, NAALADL2 polypeptide can be obtained from a biological sample from any source, such as and without limitation, a blood sample or tissue sample, e.g. a prostate, bladder, breast, esophagus, head and neck, colorectal, liver, lung, ovarian, gastric, uterus and pancreatic tissue sample.

NAALADL2 polypeptide may be in the form of a "mature protein" or may be part of a larger protein such as a fusion protein. It is often advantageous to include an additional amino acid sequence which contains secretory or leader sequences, a pre-, pro- or prepro-protein sequence, or a sequence which aids in purification such as an affinity tag, for example, but without limitation, multiple histidine residues, a FLAG tag, HA tag or myc tag.

NAALADL2 may, for example, be fused with a heterologous fusion partner such as the surface protein, known as protein D from Haemophilus Influenza B, a non-structural protein from influenza virus such as NS1, the S antigen from Hepatitis B or a protein known as LYTA such as the C terminal thereof.

An additional sequence that may provide stability during recombinant production may also
be used. Such sequences may be optionally removed as required by incorporating a cleavable sequence as an additional sequence or part thereof. Thus, a NAALADL2 polypeptide may be fused to other moieties including other polypeptides or proteins (for example, glutathione S-transferase and protein A). Such a fusion protein can be cleaved using an appropriate protease, and then separated into each protein. Such additional sequences and affinity tags are well known in the art. In addition to the above, features known in the art, such as an enhancer, a splicing signal, a polyA addition signal, a selection marker, and an SV40 replication origin can be added to an expression vector, if desired.

In one aspect the invention provides an agent capable of specific binding to NAALADL2, or a fragment thereof, or a hybridising agent capable of hybridizing to nucleic acid encoding NAALADL2 or an agent capable of detecting the activity of NAALADL2 for use in treating, screening for, detecting and/or diagnosing disease, such as cancer, and especially the diseases of the invention.

Production of Affinity Reagents to NAALADL2

In one aspect, the invention provides an affinity or immunoaffinity reagent which is capable of specific binding to NAALADL2 or a fragment thereof, for example an affinity reagent which contains or is conjugated to a detectable label or contains or is conjugated to a therapeutic moiety, such as a cytotoxic moiety. The affinity agent may, for example, be an antibody. The affinity reagent may be an isolated affinity reagent or a purified affinity reagent.

The affinity reagent for use in the invention may bind to an epitope on NAALADL2, e.g. one or more of the portions of any of SEQ ID NO: 1-2. Preferably, the affinity reagent specifically binds to the extracellular domain (e.g. the extracellular tail or extracellular loop) of NAALADL2 (e.g. to SEQ ID NO: 19).

According to those in the art, there are three main types of immunoaffinity reagent - monoclonal antibodies, phage display antibodies and smaller antibody-derived molecules such as Affibodies, Domain Antibodies (dAbs), Nanobodies, UniBodies, DARPs, Anticalins, Duocalins, Avimers or Versabodies. In general in applications according to the present invention where the use of antibodies is stated, other affinity reagents (e.g. Affibodies, Domain Antibodies, Nanobodies, UniBodies, DARPs, Anticalins, Duocalins, Avimers or Versabodies) may be employed. Such substances may be said to be capable of immunspecific binding to NAALADL2. Where appropriate the term "affinity agent" shall be construed to embrace immunoaffinity reagents and other substances capable of specific binding to NAALADL2 including but not limited to ligands, lectins, streptavidins, antibody mimetics and synthetic binding agents.

Production of Antibodies to NAALADL2

According to the invention NAALADL2, a NAALADL2 analog, a NAALADL2-related protein or a fragment or derivative of any of the foregoing may be used as an immunogen to generate antibodies which immunspecifically bind such an immunogen. Such immunogens can be isolated by any convenient means, including the methods described above. The term "antibody" as used herein refers to a peptide or polypeptide derived from, modeled after or substantially encoded by an immunoglobulin gene or immunoglobulin genes, or fragments thereof, capable of specifically binding an antigen or epitope. See, e.g. Fundamental Immunology, 3rd Edition, W.E. Paul, ed., Raven Press, N.Y. (1993); Wilson (1994; J. Immunol. Methods 175:267-273; Yarmush (1992) J. Biochem. Biophys. Methods 25:85-97. The term antibody includes antigen-binding portions, i.e.,
"antigen binding sites" (e.g. fragments, subsequences, complementarity determining regions (CDRs)) that retain capacity to bind antigen, including (i) a Fab fragment, a monovalent fragment consisting of the VL, VH, CL and CHI domains; (ii) a F(ab')2 fragment, a bivalent fragment comprising two Fab fragments linked by a disulfide bridge at the hinge region; (iii) aFd fragment consisting of the VH and CHI domains; (iv) a Fv fragment consisting of the VL and VH domains of a single arm of an antibody, (v) a dAb fragment (Ward et al., (1989) Nature 341:544-546), which consists of a VH domain; and (vi) an isolated complementarity determining region (CDR). Single chain antibodies are also included by reference in the term "antibody". Antibodies of the invention include, but are not limited to polyclonal, monoclonal, bispecific, humanized or chimeric antibodies, single chain antibodies, Fab fragments and F(ab')2 fragments, fragments produced by a Fab expression library, anti-idiotypic (anti-Id) antibodies, and epitope-binding fragments of any of the above. The immunoglobulin molecules of the invention can be of any class (e.g. IgG, IgE, IgM, IgD and IgA such as IgG) or subclass of immunoglobulin molecule.

The term "specifically binds" or "binds specifically" (or "immunospecifically binds") is not intended to indicate that an antibody binds exclusively to its intended target. Rather, an antibody "specifically binds" if its affinity for its intended target is typically about 5-fold greater when compared to its affinity for a non-target molecule. Suitably there is no significant cross-reaction or cross-binding with undesired substances, especially naturally occurring proteins or tissues of a healthy person or animal. Preferably the affinity of the antibody will be at least about 5 fold, preferably 10 fold, more preferably 25-fold, even more preferably 50-fold, and most preferably 100-fold or more, greater for a target molecule than its affinity for a non-target molecule. In some embodiments, specific binding between an antibody or other binding agent and an antigen means a binding affinity of at least $10^6$ M$^{-1}$. Antibodies may, for example, bind with affinities of at least about $10^7$ M$^{-1}$, and preferably between about $10^8$ M$^{-1}$ to about $10^9$ M$^{-1}$, about $10^9$ M$^{-1}$ to about $10^{10}$ M$^{-1}$, or about $10^{10}$ M$^{-1}$ to about $10^{11}$ M$^{-1}$.

Affinity is calculated as $K_d = \frac{k_{off}}{k_{on}}$, is the dissociation rate constant, $k_{on}$ is the association rate constant and $K_d$ is the equilibrium constant. Affinity can be determined at equilibrium by measuring the fraction bound ($r$) of labeled ligand at various concentrations ($c$). The data are graphed using the Scatchard equation: $r/c = K(n-r)$:

where
- $r$ = moles of bound ligand/mole of receptor at equilibrium;
- $c$ = free ligand concentration at equilibrium;
- $K$ = equilibrium association constant; and
- $n$ = number of ligand binding sites per receptor molecule

By graphical analysis, $r/c$ is plotted on the Y-axis versus $r$ on the X-axis thus producing a Scatchard plot. The affinity is the negative slope of the line. $k_{on}$ can be determined by competing bound labeled ligand with unlabeled excess ligand (see, e.g. U.S. Pat No. 6,316,409). The affinity of a targeting agent for its target molecule is for example at least about $1 \times 10^8$ moles/liter, such as at least about $1 \times 10^7$ moles/liter, such as at least about $1 \times 10^6$ moles/liter, especially at least about $1 \times 10^5$ moles/liter, and particularly at least about $1 \times 10^4$ moles/liter. Antibody affinity measurement by Scatchard analysis is well known in the art, see, e.g. van Erp et al., J. Immunoassy 12: 425-43, 1991; Nelson and Griswold, Comput. Methods Programs Biomed. 27: 65-8, 1988.

In one embodiment, any publicly available antibodies that recognize gene products of genes
encoding NAALADL2 may be used. In another embodiment, methods known to those skilled in the art are used to produce antibodies that recognize NAALADL2, a NAALADL2 analog, a NAALADL2-related polypeptide, or a fragment or derivative of any of the foregoing. One skilled in the art will recognize that many procedures are available for the production of antibodies, for example, as described in Antibodies, A Laboratory Manual, Ed Harlow and David Lane, Cold Spring Harbor Laboratory (1988), Cold Spring Harbor, N.Y. One skilled in the art will also appreciate that binding fragments or Fab fragments which mimic antibodies can also be prepared from genetic information by various procedures (Antibody Engineering: A Practical Approach (Borrebaeck, C , ed.), 1995, Oxford University Press, Oxford; J. Immunol. 149, 3914-3920 (1992)).

In one embodiment of the invention, antibodies to a specific domain of NAALADL2 are produced. In a specific embodiment, hydrophilic fragments of NAALADL2 are used as immunogens for antibody production.

In the production of antibodies, screening for the desired antibody can be accomplished by techniques known in the art, e.g. ELISA (enzyme-linked immunosorbent assay). For example, to select antibodies which recognize a specific domain of NAALADL2, one may assay generated hybridomas for a product which binds to a NAALADL2 fragment containing such domain. For selection of an antibody that specifically binds a first NAALADL2 homolog but which does not specifically bind to (or binds less avidly to) a second NAALADL2 homolog, one can select on the basis of positive binding to the first NAALADL2 homolog and a lack of binding to (or reduced binding to) the second NAALADL2 homolog. Similarly, for selection of an antibody that specifically binds NAALADL2 but which does not specifically bind to (or binds less avidly to) a different isoform of the same protein (such as a different glycoform having the same core peptide as NAALADL2), one can select on the basis of positive binding to NAALADL2 and a lack of binding to (or reduced binding to) the different isoform (e.g. a different glycoform). Thus, the present invention provides an antibody (such as a monoclonal antibody) that binds with greater affinity (for example at least 2-fold, such as at least 5-fold, particularly at least 10-fold greater affinity) to NAALADL2 than to a different isoform or isoforms (e.g. glycoforms) of NAALADL2.

Polyclonal antibodies which may be used in the methods of the invention are heterogeneous populations of antibody molecules derived from the sera of immunized animals. Unfractionated immune serum can also be used. Various procedures known in the art may be used for the production of polyclonal antibodies to NAALADL2, a fragment of NAALADL2, a NAALADL2-related polypeptide, or a fragment of a NAALADL2-related polypeptide. For example, one way is to purify polypeptides of interest or to synthesize the polypeptides of interest using, e.g. solid phase peptide synthesis methods well known in the art. See, e.g. Guide to Protein Purification, Murray P. Deutcher, ed., Meth. Enzymol. Vol 182 (1990); Solid Phase Peptide Synthesis, Greg B. Fields ed., Meth. Enzymol. Vol 289 (1997); Kiso et al, Chem. Pharm. Bull. (Tokyo) 38: 1192-99, 1990; Mostafavi etal, Biomed. Pept. Proteins Nucleic Acids 1: 255-60, 1995; Fujiwara et al, Chem. Pharm. Bull. (Tokyo) 44: 1326-31, 1996. The selected polypeptides may then be used to immunize by injection various host animals, including but not limited to rabbits, mice, rats, etc., to generate polyclonal or monoclonal antibodies. If NAALADL2 is purified by gel electrophoresis, NAALADL2 can be used for immunization with or without prior extraction from the polyacrylamide gel. Various adjuvants (i.e. immunostimulants) may be used to enhance the immunological response, depending on the host species, including, but not limited to, complete or
incomplete Freund's adjuvant, a mineral gel such as aluminum hydroxide, surface active substance such as lysolecithin, pluronic polyol, a peptide, an oil emulsion, keyhole limpet hemocyanin, dinitrophenol, and an adjuvant such as BCG (bacille Calmert-Guerin) or corynebacterium parvum. Additional adjuvants are also well known in the art.

For preparation of monoclonal antibodies (mAbs) directed toward NAALADL2, a fragment of NAALADL2, a NAALADL2-related polypeptide, or a fragment of a NAALADL2-related polypeptide, any technique which provides for the production of antibody molecules by continuous cell lines in culture may be used. For example, the hybridoma technique originally developed by Kohler and Milstein (1975, Nature 256:495-497), as well as the trioma technique, the human B-cell hybridoma technique (Kozbor et al., 1983, Immunology Today 4:72), and the EBV-hybridoma technique to produce human monoclonal antibodies (Cole et al., 1985, in Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, Inc., pp. 77-96). Such antibodies may be of any immunoglobulin class including IgG, IgM, IgE, IgA, IgD and any subclass thereof. The hybridoma producing the mAbs of the invention may be cultivated in vitro or in vivo. In an additional embodiment of the invention, monoclonal antibodies can be produced in germ-free animals utilizing known technology (PCT/US90/02545, incorporated herein by reference).

The monoclonal antibodies include but are not limited to human monoclonal antibodies and chimeric monoclonal antibodies (e.g. human-mouse chimeras). A chimeric antibody is a molecule in which different portions are derived from different animal species, such as those having a human immunoglobulin constant region and a variable region derived from a murine mAb, (see, e.g. Cabilly et al., U.S. Patent No. 4,816,567; and Boss et al., U.S. Patent No. 4,816,397, which are incorporated herein by reference in their entirety.) Humanized antibodies are antibody molecules from non-human species having one or more complementarity determining regions (CDRs) from the non-human species and a framework region from a human immunoglobulin molecule, (see, e.g. Queen, U.S. Patent No. 5,585,089, which is incorporated herein by reference in its entirety.)

Completely human antibodies are particularly desirable for therapeutic treatment of human subjects. Such antibodies can be produced using transgenic mice which are incapable of expressing endogenous immunoglobulin heavy and light chain genes, but which can express human heavy and light chain genes. The transgenic mice are immunized in the normal fashion with a selected antigen, e.g. all or a portion of NAALADL2. Monoclonal antibodies directed against the antigen can be obtained using conventional hybridoma technology. The human immunoglobulin transgenes harbored by the transgenic mice rearrange during B cell differentiation, and subsequently undergo
class switching and somatic mutation. Thus, using such a technique, it is possible to produce therapeutically useful IgG, IgA, IgM and IgE antibodies. For an overview of this technology for producing human antibodies, see Lonberg and Huszar (1995, *Int. Rev. Immunol.* 13:65-93). For a detailed discussion of this technology for producing human antibodies and human monoclonal antibodies and protocols for producing such antibodies, see, e.g. U.S. Patent 5,625,126; U.S. Patent 5,633,425; U.S. Patent 5,569,825; U.S. Patent 5,661,016; and U.S. Patent 5,545,806. In addition, companies such as Abgenix, Inc. (Freemont, CA) and Genpharm (San Jose, CA) can be engaged to provide human antibodies directed against a selected antigen using technology similar to that described above.

Completely human antibodies which recognize a selected epitope can be generated using a technique referred to as "guided selection". In this approach a selected non-human monoclonal antibody, e.g. a mouse antibody, is used to guide the selection of a completely human antibody recognizing the same epitope. (Jespers et al. (1994) *BioTechnology* 12:899-903).

The antibodies of the present invention can also be generated by the use of phage display technology to produce and screen libraries of polypeptides for binding to a selected target. See, e.g. Cwirla et al., *Proc. Natl. Acad. Sci. USA* 87, 6378-82, 1990; Devlin et al, *Science* 249, 404-6, 1990, Scott and Smith, *Science* 249, 386-88, 1990; and Ladner et al., U.S. Patent No. 5,571,698. A basic concept of phage display methods is the establishment of a physical association between DNA encoding a polypeptide to be screened and the polypeptide. This physical association is provided by the phage particle, which displays a polypeptide as part of a capsid enclosing the phage genome which encodes the polypeptide. The establishment of a physical association between polypeptides and their genetic material allows simultaneous mass screening of very large numbers of phage bearing different polypeptides. Phage displaying a polypeptide with affinity to a target bind to the target and these phage are enriched by affinity screening to the target. The identity of polypeptides displayed from these phage can be determined from their respective genomes. Using these methods a polypeptide identified as having a binding affinity for a desired target can then be synthesized in bulk by conventional means. See, e.g. U.S. Patent No. 6,057,098, which is hereby incorporated in its entirety, including all tables, figures, and claims. In particular, such phage can be utilized to display antigen binding domains expressed from a repertoire or combinatorial antibody library (e.g. human or murine). Phage expressing an antigen binding domain that binds the antigen of interest can be selected or identified with antigen, e.g. using labeled antigen or antigen bound or captured to a solid surface or bead. Phage used in these methods are typically filamentous phage including fd and M13 binding domains expressed from phage with Fab, Fv or disulfide stabilized Fv antibody domains recombinantly fused to either the phage gene III or gene VIII protein. Phage display methods that can be used to make the antibodies of the present invention include those disclosed in Brinkman et al, *J. Immunol. Methods* 182:41-50 (1995); Ames et al., *J. Immunol. Methods* 184:177-186 (1995); Kettleborough et al, *Eur. J. Immunol.* 24:952-958 (1994); Persic et al, *Gene* 187 9-18 (1997); Burton et al, *Advances in Immunology* 57:191-280 (1994); PCT Application No. PCT/GB91/01 134; PCT Publications WO 90/02809; WO 91/10737; WO 92/01047; WO 92/18619; WO 93/11236; WO 95/15982; WO 95/20401; and U.S. Patent Nos. 5,698,426; 5,223,409; 5,403,484; 5,580,717; 5,427,908; 5,750,753; 5,821,047; 5,571,698; 5,427,908; 5,516,637; 5,780,225; 5,658,727; 5,733,743 and 5,969,108; each of which is incorporated herein by reference in its entirety.

As described in the above references, after phage selection, the antibody coding regions
from the phage can be isolated and used to generate whole antibodies, including human antibodies, or any other desired antigen binding fragment, and expressed in any desired host, including mammalian cells, insect cells, plant cells, yeast, and bacteria, e.g. as described in detail below. For example, techniques to recombinantly produce Fab, Fab' and F(ab')2 fragments can also be employed using methods known in the art such as those disclosed in PCT publication WO 92/22324; Mullinax et al., BioTechniques 12(6):864-869 (1992); and Sawai et al., AJRI 34:26-34 (1995); and Better et al., Science 240:1041-1043 (1988) (said references incorporated by reference in their entireties).

Examples of techniques which can be used to produce single-chain Fv's and antibodies include those described in U.S. Patents 4,946,778 and 5,258,498; Huston et al, Methods in Enzymology 203:46-88 (1991); Shu et al, PNAS 90:7995-7999 (1993); and Skerra et al, Science 240:1038-1040 (1988).

The invention further provides for the use of bispecific antibodies, which can be made by methods known in the art. Traditional production of full length bispecific antibodies is based on the coexpression of two immunoglobulin heavy chain-light chain pairs, where the two chains have different specificities (Milstein et al., 1983, Nature 305:537-539). Because of the random assortment of immunoglobulin heavy and light chains, these hybridomas (quadromas) produce a potential mixture of 10 different antibody molecules, of which only one has the correct bispecific structure. Purification of the correct molecule, which is usually done by affinity chromatography steps, is rather cumbersome, and the product yields are low. Similar procedures are disclosed in WO 93/08829, published 13 May 1993, and in Traunecker et al., 1991, EMBO J. 10:3655-3659.

According to a different and more preferred approach, antibody variable domains with the desired binding specificities (antibody-antigen combining sites) are fused to immunoglobulin constant domain sequences. The fusion preferably is with an immunoglobulin heavy chain constant domain, comprising at least part of the hinge, CH2, and CH3 regions. It is preferred to have the first heavy-chain constant region (CHI) containing the site necessary for light chain binding, present in at least one of the fusions. DNAs encoding the immunoglobulin heavy chain fusions and, if desired, the immunoglobulin light chain, are inserted into separate expression vectors, and are co-transfected into a suitable host organism. This provides for great flexibility in adjusting the mutual proportions of the three polypeptide fragments in embodiments when unequal ratios of the three polypeptide chains used in the construction provide the optimum yields. It is, however, possible to insert the coding sequences for two or all three polypeptide chains in one expression vector when the expression of at least two polypeptide chains in equal ratios results in high yields or when the ratios are of no particular significance.

In a preferred embodiment of this approach, the bispecific antibodies are composed of a hybrid immunoglobulin heavy chain with a first binding specificity in one arm, and a hybrid immunoglobulin heavy chain-light chain pair (providing a second binding specificity) in the other arm. It was found that this asymmetric structure facilitates the separation of the desired bispecific compound from unwanted immunoglobulin chain combinations, as the presence of an immunoglobulin light chain in only one half of the bispecific molecule provides for a facile way of separation. This approach is disclosed in WO 94/04690 published March 3, 1994. For further details for generating bispecific antibodies see, for example, Suress et al., Methods in Enzymology, 1986, 121:210.
The invention provides functionally active fragments, derivatives or analogs of the anti-NAALADL2 immunoglobulin molecules. Functionally active means that the fragment, derivative or analog is able to elicit anti-anti-idiotype antibodies (i.e., tertiary antibodies) that recognize the same antigen that is recognized by the antibody from which the fragment, derivative or analog is derived. Specifically, in a preferred embodiment the antigenicity of the idiotype of the immunoglobulin molecule may be enhanced by deletion of framework and CDR sequences that are C-terminal to the CDR sequence that specifically recognizes the antigen. To determine which CDR sequences bind the antigen, synthetic peptides containing the CDR sequences can be used in binding assays with the antigen by any binding assay method known in the art.

The present invention provides antibody fragments such as, but not limited to, F(ab’)2 fragments and Fab fragments. Antibody fragments which recognize specific epitopes may be generated by known techniques. F(ab’)2 fragments consist of the variable region, the light chain constant region and the CHI domain of the heavy chain and are generated by pepsin digestion of the antibody molecule. Fab fragments are generated by reducing the disulfide bridges of the F(ab’)2 fragments. The invention also provides heavy chain and light chain dimers of the antibodies of the invention, or any minimal fragment thereof such as Fvs or single chain antibodies (SCAs) (e.g. as described in U.S. Patent 4,946,778; Bird, 1988, Science 242:423-42; Huston et al., 1988, Proc. Natl. Acad. Sci. USA 85:5879-5883; and Ward et al., 1989, Nature 334:544-54), or any other molecule with the same specificity as the antibody of the invention. Single chain antibodies are formed by linking the heavy and light chain fragments of the Fv region via an amino acid bridge, resulting in a single chain polypeptide. Techniques for the assembly of functional Fv fragments in E. coli may be used (Skerra et al., 1988, Science 242:1038-1041).

In other embodiments, the invention provides fusion proteins of the immunoglobulins of the invention (or functionally active fragments thereof), for example in which the immunoglobulin is fused via a covalent bond (e.g. a peptide bond), at either the N-terminus or the C-terminus to an amino acid sequence of another protein (or portion thereof, preferably at least 10, 20 or 50 amino acid portion of the protein) that is not the immunoglobulin. Preferably the immunoglobulin, or fragment thereof, is covalently linked to the other protein at the N-terminus of the constant domain. As stated above, such fusion proteins may facilitate purification, increase half-life in vivo, and enhance the delivery of an antigen across an epithelial barrier to the immune system.

The immunoglobulins of the invention include analogs and derivatives that are modified, i.e., by the covalent attachment of any type of molecule as long as such covalent attachment does not impair immunospecific binding. For example, but not by way of limitation, the derivatives and analogs of the immunoglobulins include those that have been further modified, e.g. by glycosylation, acetylation, pegylation, phosphorylation, amidation, derivatization by known protecting/blocking groups, proteolytic cleavage, linkage to a cellular ligand or other protein, etc. Any of numerous chemical modifications may be carried out by known techniques, including, but not limited to specific chemical cleavage, acetylation, formylation, etc. Additionally, the analog or derivative may contain one or more non-classical amino acids.

The foregoing antibodies can be used in methods known in the art relating to the localization and activity of NAALADL2, e.g. for imaging this protein, measuring levels thereof in appropriate physiological samples, in diagnostic methods, etc.
Production of Affibodies to NAALADL2

Affibody molecules represent a new class of affinity proteins based on a 58-amino acid residue protein domain, derived from one of the IgG-binding domains of staphylococcal protein A. This three helix bundle domain has been used as a scaffold for the construction of combinatorial phagemid libraries, from which Affibody variants that target the desired molecules can be selected using phage display technology (Nord K, Gunneriusson E, Ringdahl J, Stahl S, Uhlen M, Nygren PA, Binding proteins selected from combinatorial libraries of an α-helical bacterial receptor domain, Nat Biotechnol 1997;15:772-7. Ronmark J, Gronlund H, Uhlen M, Nygren PA, Human immunoglobulin A (IgA)-specific ligands from combinatorial engineering of protein A, Eur J Biochem 2002;269:2647-55.). The simple, robust structure of Affibody molecules in combination with their low molecular weight (6 kDa), make them suitable for a wide variety of applications, for instance, as detection reagents (Ronmark J, Hansson M, Nguyen T, et al, Construction and characterization of Affibody-Fc chimeras produced in Escherichia coli, J Immunol Methods 2002;261 :199-211) and to inhibit receptor interactions (Sandstrom K, Xu Z, Forsberg G, Nygren PA, Inhibition of the CD28-CD80 co-stimulation signal by a CD28-binding Affibody ligand developed by combinatorial protein engineering, Protein Eng 2003;16:691-7). Further details of Affibodies and methods of production thereof may be obtained by reference to US Patent No 5831012 which is herein incorporated by reference in its entirety.

Labelled Affibodies may also be useful in imaging applications for determining abundance of isoforms.

Production of Domain Antibodies to NAALADL2

References to antibodies herein embrace references to Domain Antibodies. Domain Antibodies (dAbs) are the smallest functional binding units of antibodies, corresponding to the variable regions of either the heavy (VH) or light (VL) chains of human antibodies. Domain Antibodies have a molecular weight of approximately 13 kDa. Domantis has developed a series of large and highly functional libraries of fully human VH and VL dAbs (more than ten billion different sequences in each library), and uses these libraries to select dAbs that are specific to therapeutic targets. In contrast to many conventional antibodies, Domain Antibodies are well expressed in bacterial, yeast, and mammalian cell systems. Further details of domain antibodies and methods of production thereof may be obtained by reference to US Patent 6,291,158; 6,582,915; 6,593,081; 6,172,197; 6,696,245; US Serial No. 2004/01 10941; European patent application No. 1433846 and European Patents 0368684 and 0616640; WO05/035572, WO04/101790, WO04/081026, WO04/058821, WO04/003019 and WO03/002609, each of which is herein incorporated by reference in its entirety.

Production of Nanobodies to NAALADL2

Nanobodies are antibody-derived therapeutic proteins that contain the unique structural and functional properties of naturally-occurring heavy-chain antibodies. These heavy-chain antibodies contain a single variable domain (VHH) and two constant domains (C_H2 and C_H3). Importantly, the cloned and isolated VHH domain is a perfectly stable polypeptide harbouring the full antigen-binding capacity of the original heavy-chain antibody. Nanobodies have a high homology with the V_H domains of human antibodies and can be further humanised without any loss of activity. Importantly, Nanobodies have a low immunogenic potential, which has been confirmed in primate studies with Nanobody lead compounds.
Nanobodies combine the advantages of conventional antibodies with important features of small molecule drugs. Like conventional antibodies, Nanobodies show high target specificity, high affinity for their target and low inherent toxicity. However, like small molecule drugs they can inhibit enzymes and readily access receptor clefts. Furthermore, Nanobodies are extremely stable, can be administered by means other than injection (see e.g. WO 04/041 867, which is herein incorporated by reference in its entirety) and are easy to manufacture. Other advantages of Nanobodies include recognising uncommon or hidden epitopes as a result of their small size, binding into cavities or active sites of protein targets with high affinity and selectivity due to their unique 3-dimensional, drug format flexibility, tailoring of half-life and ease and speed of drug discovery.

Nanobodies are encoded by single genes and are efficiently produced in almost all prokaryotic and eukaryotic hosts e.g. E. coli (see e.g. US 6,765,087, which is herein incorporated by reference in its entirety), moulds (for example Aspergillus or Trichoderma) and yeast (for example Saccharomyces, Kluyveromyces, Hansenula or Pichid) (see e.g. US 6,838,254, which is herein incorporated by reference in its entirety). The production process is scalable and multi-kilogram quantities of Nanobodies have been produced. Because Nanobodies exhibit a superior stability compared with conventional antibodies, they can be formulated as a long shelf-life, ready-to-use solution.

The Nanoclon method (see e.g. WO 06/079372, which is herein incorporated by reference in its entirety) is a proprietary method for generating Nanobodies against a desired target, based on automated high-throughout selection of B-cells.

Production of UniBodies to NAALADL2

UniBodies are another antibody fragment technology; however this one is based upon the removal of the hinge region of IgG4 antibodies. The deletion of the hinge region results in a molecule that is essentially half the size of traditional IgG4 antibodies and has a univalent binding region rather than the bivalent binding region of IgG4 antibodies. It is also well known that IgG4 antibodies are inert and thus do not interact with the immune system, which may be advantageous for the treatment of diseases where an immune response is not desired, and this advantage is passed onto UniBodies. For example, UniBodies may function to inhibit or silence, but not kill, the cells to which they are bound. Additionally, UniBody binding to cancer cells do not stimulate them to proliferate. Furthermore, because UniBodies are about half the size of traditional IgG4 antibodies, they may show better distribution over larger solid tumors with potentially advantageous efficacy. UniBodies are cleared from the body at a similar rate to whole IgG4 antibodies and are able to bind with a similar affinity for their antigens as whole antibodies. Further details of UniBodies may be obtained by reference to patent WO2007/059782, which is herein incorporated by reference in its entirety.

Production of DARPins to NAALADL2

DARPins (Designed Ankyrin Repeat Proteins) are one example of an antibody mimetic DRP (Designed Repeat Protein) technology that has been developed to exploit the binding abilities of non-antibody polypeptides. Repeat proteins such as ankyrin or leucine-rich repeat proteins, are ubiquitous binding molecules, which occur, unlike antibodies, intra- and extracellularly. Their unique modular architecture features repeating structural units (repeats), which stack together to form elongated repeat domains displaying variable and modular target-binding surfaces. Based on
this modularity, combinatorial libraries of polypeptides with highly diversified binding specificities can be generated. This strategy includes the consensus design of self-compatible repeats displaying variable surface residues and their random assembly into repeat domains.

DARPins can be produced in bacterial expression systems at very high yields and they belong to the most stable proteins known. Highly specific, high-affinity DARPins to a broad range of target proteins, including human receptors, cytokines, kinases, human proteases, viruses and membrane proteins, have been selected. DARPins having affinities in the single-digit nanomolar to picomolar range can be obtained.

DARPins have been used in a wide range of applications, including ELISA, sandwich ELISA, flow cytometric analysis (FACS), immunohistochemistry (IHC), chip applications, affinity purification or Western blotting. DARPins also proved to be highly active in the intracellular compartment for example as intracellular marker proteins fused to green fluorescent protein (GFP). DARPins were further used to inhibit viral entry with \( IC_{50} \) in the pM range. DARPins are not only ideal to block protein-protein interactions, but also to inhibit enzymes. Proteases, kinases and transporters have been successfully inhibited, most often an allosteric inhibition mode. Very fast and specific enrichments on the tumor and very favorable tumor to blood ratios make DARPins well suited for in vivo diagnostics or therapeutic approaches.

Additional information regarding DARPins and other DRP technologies can be found in US Patent Application Publication No. 2004/0132028, and International Patent Application Publication No. WO02/20565, both of which are hereby incorporated by reference in their entirety.

**Production of Anticalins to NAALADL2**

Anticalins are an additional antibody mimetic technology, however in this case the binding specificity is derived from lipocalins, a family of low molecular weight proteins that are naturally and abundantly expressed in human tissues and body fluids. Lipocalins have evolved to perform a range of functions in vivo associated with the physiological transport and storage of chemically sensitive or insoluble compounds. Lipocalins have a robust intrinsic structure comprising a highly conserved \( \beta \)-barrel which supports four loops at one terminus of the protein. These loops form the entrance to a binding pocket and conformational differences in this part of the molecule account for the variation in binding specificity between individual lipocalins.

While the overall structure of hypervariable loops supported by a conserved \( \beta \)-sheet framework is reminiscent of immunoglobulins, lipocalins differ considerably from antibodies in terms of size, being composed of a single polypeptide chain of 160-180 amino acids which is marginally larger than a single immunoglobulin domain.

Lipocalins are cloned and their loops are subjected to engineering in order to create Anticalins. Libraries of structurally diverse Anticalins have been generated and Anticalin display allows the selection and screening of binding function, followed by the expression and production of soluble protein for further analysis in prokaryotic or eukaryotic systems. Studies have successfully demonstrated that Anticalins can be developed that are specific for virtually any human target protein; they can be isolated and binding affinities in the nanomolar or higher range can be obtained.

Anticalins can also be formatted as dual targeting proteins, so-called Duocalins. A Duocalin binds two separate therapeutic targets in one easily produced monomeric protein using standard manufacturing processes while retaining target specificity and affinity regardless of the structural orientation of its two binding domains.
Modulation of multiple targets through a single molecule is particularly advantageous in diseases known to involve more than a single causative factor. Moreover, bi- or multivalent binding formats such as Duocalins have significant potential in targeting cell surface molecules in disease, mediating agonistic effects on signal transduction pathways or inducing enhanced internalization effects via binding and clustering of cell surface receptors. Furthermore, the high intrinsic stability of Duocalins is comparable to monomeric Anticalins, offering flexible formulation and delivery potential for Duocalins.

Additional information regarding Anticalins can be found in US Patent No. 7,250,297 and International Patent Application Publication No. WO 99/16873, both of which are hereby incorporated by reference in their entirety.

**Production of Avimers to NAALADL2**

Avimers are evolved from a large family of human extracellular receptor domains by in vitro exon shuffling and phage display, generating multidomain proteins with binding and inhibitory properties. Linking multiple independent binding domains has been shown to create avidity and results in improved affinity and specificity compared with conventional single-epitope binding proteins. Other potential advantages include simple and efficient production of multitarget-specific molecules in Escherichia coli, improved thermostability and resistance to proteases. Avimers with sub-nanomolar affinities have been obtained against a variety of targets.

**Production of Versabodies to NAALADL2**

Versabodies are small proteins of 3-5 kDa with >15% cysteines, which form a high disulfide density scaffold, replacing the hydrophobic core that typical proteins have. The replacement of a large number of hydrophobic amino acids, comprising the hydrophobic core, with a small number of disulfides results in a protein that is smaller, more hydrophilic (less aggregation and non-specific binding), more resistant to proteases and heat, and has a lower density of T-cell epitopes, because the residues that contribute most to MHC presentation are hydrophobic. All four of these properties are well-known to affect immunogenicity, and together they are expected to cause a large decrease in immunogenicity.

The inspiration for Versabodies comes from the natural injectable biopharmaceuticals produced by leeches, snakes, spiders, scorpions, snails, and anemones, which are known to exhibit unexpectedly low immunogenicity. Starting with selected natural protein families, by design and by screening the size, hydrophobicity, proteolytic antigen processing, and epitope density are minimized to levels far below the average for natural injectable proteins.

Given the structure of Versabodies, these antibody mimetics offer a versatile format that includes multi-valency, multi-specificity, a diversity of half-life mechanisms, tissue targeting modules and the absence of the antibody Fc region. Furthermore, Versabodies are manufactured in E. coli at high yields, and because of their hydrophilicity and small size, Versabodies are highly soluble and can be formulated to high concentrations. Versabodies are exceptionally heat stable (they can be boiled) and offer extended shelf-life.

Additional information regarding Versabodies can be found in US Patent Application
Publication No. 2007/0191272 which is hereby incorporated by reference in its entirety.

**Expression of Affinity Reagents**

**Expression of Antibodies**

The antibodies of the invention can be produced by any method known in the art for the synthesis of antibodies, in particular, by chemical synthesis or by recombinant expression, and are preferably produced by recombinant expression techniques.

Recombinant expression of antibodies, or fragments, derivatives or analogs thereof, requires construction of a nucleic acid that encodes the antibody. If the nucleotide sequence of the antibody is known, a nucleic acid encoding the antibody may be assembled from chemically synthesized oligonucleotides (e.g. as described in Kutmeier et al., 1994, *BioTechniques* 17:242), which, briefly, involves the synthesis of overlapping oligonucleotides containing portions of the sequence encoding antibody, annealing and ligation of those oligonucleotides, and then amplification of the ligated oligonucleotides by PCR.

Alternatively, the nucleic acid encoding the antibody may be obtained by cloning the antibody. If a clone containing the nucleic acid encoding the particular antibody is not available, but the sequence of the antibody molecule is known, a nucleic acid encoding the antibody may be obtained from a suitable source (e.g. an antibody cDNA library, or cDNA library generated from any tissue or cells expressing the antibody) by PCR amplification using synthetic primers hybridizable to the 3' and 5' ends of the sequence or by cloning using an oligonucleotide probe specific for the particular gene sequence.

If an antibody molecule that specifically recognizes a particular antigen is not available (or a source for a cDNA library for cloning a nucleic acid encoding such an antibody), antibodies specific for a particular antigen may be generated by any method known in the art, for example, by immunizing an animal, such as a rabbit, to generate polyclonal antibodies or, for example, by generating monoclonal antibodies. Alternatively, a clone encoding at least the Fab portion of the antibody may be obtained by screening Fab expression libraries (e.g. as described in Huse et al., 1989, *Science* 246:1275-1281) for clones of Fab fragments that bind the specific antigen or by screening antibody libraries (see, e.g. Clackson et al., 1991, *Nature* 352:624; Hane et al., 1997 *Proc. Natl. Acad. Sci. USA* 94:4937).

Once a nucleic acid encoding at least the variable domain of the antibody molecule is obtained, it may be introduced into a vector containing the nucleotide sequence encoding the constant region of the antibody molecule (see, e.g. PCT Publication WO 86/05807; PCT Publication WO 89/01036; and U.S. Patent No. 5,122,464). Vectors containing the complete light or heavy chain for co-expression with the nucleic acid to allow the expression of a complete antibody molecule are also available. Then, the nucleic acid encoding the antibody can be used to introduce the nucleotide substitution(s) or deletion(s) necessary to substitute (or delete) the one or more variable region cysteine residues participating in an intrachain disulfide bond with an amino acid residue that does not contain a sulphydryl group. Such modifications can be carried out by any method known in the art for the introduction of specific mutations or deletions in a nucleotide sequence, for example, but not limited to, chemical mutagenesis, in vitro site directed mutagenesis (Hutchinson et al., 1978, *J. Biol. Chem.* 253:6551), PCT based methods, etc.

Takeda *et al.*, 1985, *Nature* 314:452-454) by splicing genes from a mouse antibody molecule of appropriate antigen specificity together with genes from a human antibody molecule of appropriate biological activity can be used. As described *supra*, a chimeric antibody is a molecule in which different portions are derived from different animal species, such as those having a variable region derived from a murine mAb and a human antibody constant region, e.g. humanized antibodies.

Once a nucleic acid encoding an antibody molecule of the invention has been obtained, the vector for the production of the antibody molecule may be produced by recombinant DNA technology using techniques well known in the art. Thus, methods for preparing NAALDL2 by expressing nucleic acid containing the antibody molecule sequences are described herein. Methods which are well known to those skilled in the art can be used to construct expression vectors containing an antibody molecule coding sequences and appropriate transcriptional and translational control signals. These methods include, for example, *in vitro* recombinant DNA techniques, synthetic techniques, and *in vivo* genetic recombination. See, for example, the techniques described in Sambrook *et al.*, (1990, Molecular Cloning, A Laboratory Manual, 2nd Ed., Cold Spring Harbor Laboratory, Cold Spring Harbor, NY) and Ausubel *et al.* (eds., 1998, Current Protocols in Molecular Biology, John Wiley & Sons, NY).

The expression vector is transferred to a host cell by conventional techniques and the transfected cells are then cultured by conventional techniques to produce an antibody of the invention.

The host cells used to express a recombinant antibody of the invention may be either bacterial cells such as *Escherichia coli*, or, preferably, eukaryotic cells, especially for the expression of whole recombinant antibody molecule. In particular, mammalian cells such as Chinese hamster ovary cells (CHO), in conjunction with a vector such as the major intermediate early gene promoter element from human cytomegalovirus are an effective expression system for antibodies (Foecking *et al.*, 1986, *Gene* 45:101; Cockett *et al.*, 1990, *BioTechnology* 8:2).

A variety of host-expression vector systems may be utilized to express an antibody molecule of the invention. Such host-expression systems represent vehicles by which the coding sequences of interest may be produced and subsequently purified, but also represent cells which may, when transformed or transfected with the appropriate nucleotide coding sequences, express the antibody molecule of the invention *in situ*. These include but are not limited to microorganisms such as bacteria (e.g. *E. coli, B. subtilis*) transformed with recombinant bacteriophage DNA, plasmid DNA or cosmid DNA expression vectors containing antibody coding sequences; yeast (e.g. *Saccharomyces, Pichia*) transformed with recombinant yeast expression vectors containing antibody coding sequences; insect cell systems infected with recombinant virus expression vectors (e.g. baculovirus) containing the antibody coding sequences; plant cell systems infected with recombinant virus expression vectors (e.g. cauliflower mosaic virus, CaMV; tobacco mosaic virus, TMV) or transformed with recombinant plasmid expression vectors (e.g. Ti plasmid) containing antibody coding sequences; or mammalian cell systems (e.g. COS, CHO, BHK, 293, 3T3 cells) harboring recombinant expression constructs containing promoters derived from the genome of mammalian cells (e.g. metallothionein promoter) or from mammalian viruses (e.g. the adenovirus late promoter; the vaccinia virus 7.5K promoter).

In bacterial systems, a number of expression vectors may be advantageously selected depending upon the use intended for the antibody molecule being expressed. For example, when a
large quantity of such a protein is to be produced, for the generation of pharmaceutical compositions
comprising an antibody molecule, vectors which direct the expression of high levels of fusion
protein products that are readily purified may be desirable. Such vectors include, but are not limited,
to the E. coli expression vector pUR278 (Ruther et al., 1983, EMBOJ. 2:1791), in which the
antibody coding sequence may be ligated individually into the vector in frame with the lac Z coding
region so that a fusion protein is produced; pIN vectors (Inouye & Inouye, 1985, Nucleic Acids Res.
vectors may also be used to express foreign polypeptides as fusion proteins with glutathione
S-transferase (GST). In general, such fusion proteins are soluble and can easily be purified from
lysed cells by adsorption and binding to a matrix glutathione-agarose beads followed by elution in
the presence of free glutathione. The pGEX vectors are designed to include thrombin or factor Xa
protease cleavage sites so that the cloned target gene product can be released from the GST moiety.

In an insect system, Autographa californica nuclear polyhedrosis virus (AcNPV) is used as
a vector to express foreign genes. The virus grows in Spodoptera frugiperda cells. The antibody
coding sequence may be cloned individually into non-essential regions (for example the polyhedrin
gene) of the virus and placed under control of an AcNPV promoter (for example the polyhedrin
promoter). In mammalian host cells, a number of viral-based expression systems (e.g. an adenovirus
expression system) may be utilized.

As discussed above, a host cell strain may be chosen which modulates the expression of the
inserted sequences, or modifies and processes the gene product in the specific fashion desired. Such
modifications (e.g. glycosylation) and processing (e.g. cleavage) of protein products may be
important for the function of the protein.

For long-term, stable expression of recombinant antibodies, stable expression is
preferred. For example, cell lines that stably express an antibody of interest can be produced by
transfecting the cells with an expression vector comprising the nucleotide sequence of the antibody
and the nucleotide sequence of a selectable (e.g. neomycin or hygromycin), and selecting for
expression of the selectable marker. Such engineered cell lines may be particularly useful in
screening and evaluation of compounds that interact directly or indirectly with the antibody
molecule.

The expression levels of the antibody molecule can be increased by vector amplification (for
a review, see Bebbington and Hentschel, The use of vectors based on gene amplification for the
York, 1987). When a marker in the vector system expressing antibody is amplifiable, increase in the
level of inhibitor present in culture of host cell will increase the number of copies of the marker
gene. Since the amplified region is associated with the antibody gene, production of the antibody
will also increase (Crouse et al., 1983, Mol. Cell. Biol. 3:257).

The host cell may be co-transfected with two expression vectors of the invention, the first
vector encoding a heavy chain derived polypeptide and the second vector encoding a light chain
derived polypeptide. The two vectors may contain identical selectable markers which enable equal
expression of heavy and light chain polypeptides. Alternatively, a single vector may be used which
encodes both heavy and light chain polypeptides. In such situations, the light chain should be placed
before the heavy chain to avoid an excess of toxic free heavy chain (Proudfoot, 1986, Nature
and light chains may comprise cDNA or genomic DNA.

Once the antibody molecule of the invention has been recombinantly expressed, it may be purified by any method known in the art for purification of an antibody molecule, for example, by chromatography (e.g. ion exchange chromatography, affinity chromatography such as with protein A or specific antigen, and sizing column chromatography), centrifugation, differential solubility, or by any other standard technique for the purification of proteins.

Alternatively, any fusion protein may be readily purified by utilizing an antibody specific for the fusion protein being expressed. For example, a system described by Janknecht et al. allows for the ready purification of non-denatured fusion proteins expressed in human cell lines (Janknecht et al., 1991, Proc. Natl. Acad. Sci. USA 88:8972-897). In this system, the gene of interest is subcloned into a vaccinia recombinant plasmid such that the open reading frame of the gene is translationally fused to an amino-terminal tag consisting of six histidine residues. The tag serves as a matrix binding domain for the fusion protein. Extracts from cells infected with recombinant vaccinia virus are loaded onto Ni²⁺ nitriloacetic acid-agarose columns and histidine-tagged proteins are selectively eluted with imidazole-containing buffers.

The antibodies that are generated by these methods may then be selected by first screening for affinity and specificity with the purified polypeptide of interest and, if required, comparing the results to the affinity and specificity of the antibodies with polypeptides that are desired to be excluded from binding. The screening procedure can involve immobilization of the purified polypeptides in separate wells of microtiter plates. The solution containing a potential antibody or groups of antibodies is then placed into the respective microtiter wells and incubated for about 30 min to 2 h. The microtiter wells are then washed and a labeled secondary antibody (for example, an anti-mouse antibody conjugated to alkaline phosphatase if the raised antibodies are mouse antibodies) is added to the wells and incubated for about 30 min and then washed. Substrate is added to the wells and a color reaction will appear where antibody to the immobilized polypeptide(s) is present.

The antibodies so identified may then be further analyzed for affinity and specificity in the assay design selected. In the development of immunoassays for a target protein, the purified target protein acts as a standard with which to judge the sensitivity and specificity of the immunoassay using the antibodies that have been selected. Because the binding affinity of various antibodies may differ; certain antibody pairs (e.g. in sandwich assays) may interfere with one another sterically, etc., assay performance of an antibody may be a more important measure than absolute affinity and specificity of an antibody.

Those skilled in the art will recognize that many approaches can be taken in producing antibodies or binding fragments and screening and selecting for affinity and specificity for the various polypeptides, but these approaches do not change the scope of the invention.

For therapeutic applications, antibodies (particularly monoclonal antibodies) may suitably be human or humanized animal (e.g. mouse) antibodies. Animal antibodies may be raised in animals using the human protein (e.g. NAALADL2) as immunogen. Humanisation typically involves grafting CDRs identified thereby into human framework regions. Normally some subsequent retromutation to optimize the conformation of chains is required. Such processes are known to persons skilled in the art.
Expression of Affibodies

The biosensor analyses to investigate the optimal Affibody variants using biosensor binding studies has also been described elsewhere (Ronnmark J, Gronlund H, Uhlen, M., Nygren P.A., Human immunoglobulin A (IgA)-specific ligands from combinatorial engineering of protein A, 2002, **Eur. J. Biochem.** 269, 2647-2655.).

Affinity Reagent Modifications

In a preferred embodiment, anti-NAALDL2 affinity reagents such as antibodies or fragments thereof are conjugated to a diagnostic moiety (such as a detectable label) or a therapeutic moiety. The antibodies can be used for diagnosis or to determine the efficacy of a given treatment regimen. Detection can be facilitated by coupling the antibody to a detectable substance (label). Examples of detectable substances include various enzymes, prosthetic groups, fluorescent materials, luminescent materials, bioluminescent materials, radioactive nuclides, positron emitting metals (for use in positron emission tomography), and nonradioactive paramagnetic metal ions. See generally U.S. Patent No. 4,741,900 for metal ions which can be conjugated to antibodies for use as diagnostics according to the present invention. Suitable enzymes include horseradish peroxidase, alkaline phosphatase, beta-galactosidase, or acetylcholinesterase; suitable prosthetic groups include streptavidin, avidin and biotin; suitable fluorescent materials include umbelliferone, fluorescein, fluorescein isothiocyanate, rhodamine, dichlorotriazinylamine fluorescein, dansyl chloride and phycoerythrin; suitable luminescent materials include luminol; suitable bioluminescent materials include luciferase, luciferin, and aequorin; and suitable radioactive nuclides include $^{125}$I, $^{131}$I, $^{11}$In and $^{68}$Ga may also be employed.

As indicated above affinity reagents, such as antibodies for use in the invention, may be conjugated to a therapeutic moiety, such as a cytotoxin, a drug (e.g. an immunosuppressant) or a radiotoxin. Such conjugates are referred to herein as "immunoconjugates". Immunoconjugates that include one or more cytotoxins are referred to as "immunotoxins". A cytotoxin or cytotoxic agent includes any agent that is detrimental to (e.g. kills) cells. Examples include taxol, cytochalasin B, gramicidin D, ethidium bromide, etemine, mitomycin, etoposide, tenoposide, vincristine, vinblastine, colchicine, doxorubicin, daunorubicin, dhydroxy anthracin dione, mitoxantrone, mithramycin, actinomycin D, 1-dehydrotestosterone, glucocorticoids, procaine, tetracaine, lidocaine, propranolol, and puromycin and analogs or homologs thereof. Therapeutic agents also include, for example, antimitabolites (e.g. methotrexate, 6-mercaptopurine, 6-thioguanine, cytarabine, 5-fluorouracil decarbazaine), alkylating agents (e.g. mechlorethamine, thioepa chlorambucil, melphalan, carmustine (BSNU) and lomustine (CCNU), cyclophosphamide, busulfan, dibromomannitol, streptozotocin, mitomycin C, and cis-dichlorodiamine platinum (II) (DDP) cisplatin), anthracyclines (e.g. daunorubicin (formerly daunomycin) and doxorubicin), antibiotics
(e.g. dactinomycin (formerly actinomycin), bleomycin, mithramycin, and anthramycin (AMC)), and
anti-mitotic agents (e.g. vincristine and vinblastine).

Other preferred examples of therapeutic cytotoxins that can be conjugated to an antibody of the invention include duocarmycins, calicheamicins, maytansines and auristatins, and derivatives thereof. An example of a calicheamicin antibody conjugate is commercially available (Mylotarg®; American Home Products).

Cytotoxins can be conjugated to antibodies of the invention using linker technology available in the art. Examples of linker types that have been used to conjugate a cytotoxin to an antibody include, but are not limited to, hydrazones, thioethers, esters, disulfides and peptide-containing linkers. A linker can be chosen that is, for example, susceptible to cleavage by low pH within the lysosomal compartment or susceptible to cleavage by proteases, such as proteases preferentially expressed in tumor tissue such as cathepsins (e.g. cathepsins B, C, D).

Affinity reagents can also be conjugated to a radioactive isotope to generate cytotoxic radiopharmaceuticals, also referred to as radioimmunoconjugates. Examples of radioactive isotopes that can be conjugated to antibodies for use diagnostically or therapeutically include, but are not limited to, iodine131, indium111, yttrium90 and lutetium177. Methods for preparing radioimmunoconjugates are established in the art. Examples of radioimmunoconjugates are commercially available, including Zevalin® (IDEC Pharmaceuticals) and Bexxar® (Corixa Pharmaceuticals), and similar methods can be used to prepare radioimmunoconjugates using the antibodies of the invention.

Affinity reagents can also be conjugated to a phthalocyanine dye referred to hereafter as phthalocyanine conjugates. Examples of phthalocyanine dyes that can be conjugated to antibodies for use diagnostically or therapeutically include, but are not limited to, IR700. Methods for preparing phthalocyanine conjugates are described, for example, in Mitsunaga M, Ogawa M, Kosaka N, Rosenblum LT, Choyke PL and Kobayashi H (2001) Nat Med. 2011 Nov 6. doi: 10.1038/nm.2554.

The conjugates can be used to modify a given biological response, and the drug moiety is not to be construed as limited to classical chemical therapeutic agents. For example, the drug moiety may be a protein or polypeptide possessing a desired biological activity. Such proteins may include, for example, an enzymatically active toxin, or active fragment thereof, such as abrin, ricin A, pseudomonas exotoxin, or diphtheria toxin; a protein such as tumor necrosis factor or interferon-γ; or, biological response modifiers such as, for example, lymphokines, interleukin-1 ("IL-1"), interleukin-2 ("IL-2"), interleukin-6 ("IL-6"), granulocyte macrophage colony stimulating factor...

Alternatively, an antibody can be conjugated to a second antibody to form an antibody heteroconjugate as described by Segal in U.S. Patent No. 4,676,980.

An antibody with or without a therapeutic moiety conjugated to it can be used as a therapeutic that is administered alone or in combination with cytokotoxic factor(s) and/or cytokine(s).

The invention also provides for fully human, or humanised antibodies that induce antibody-directed cell-mediated cytotoxicity (ADCC). A fully human antibody is one in which the protein sequences are encoded by naturally occurring human immunoglobulin sequences, either from isolated antibody-producing human B-lymphocytes, or from transgenic murine B-lymphocytes of mice in which the murine immunoglobulin coding chromosomal regions have been replaced by orthologous human sequences. Transgenic antibodies of the latter type include, but are not restricted to, HuMab (Medarex, Inc CA) and XenoMouse (Abgenix Inc., CA). A humanised antibody is one in which the constant region of a non-human antibody molecule of appropriate antigen specificity, is replaced by the constant region of a human antibody, preferably of the IgG subtype, with appropriate effector functions (Morrison et al., 1984, Proc. Natl. Acad. Sci. 81:851-855; Neuberger et al., 1984, Nature 312:604-608; Takeda et al. 1985, Nature 314:452-454). Appropriate effector functions include ADCC, which is a natural process by which fully-human antibodies or humanized antibodies, when bound to targets on the surface of cancer cells, switch on the cell killing properties of lymphocytes that are part of the normal immune system. These active lymphocytes, called Natural Killer (NK) cells, use a cytotoxic process to destroy living cells to which the antibodies are bound. ADCC activity may be detected and quantified by measuring release of Europium (Eu³⁺) from Eu³⁺ labelled, living cells in the presence of an antigen-specific antibody and peripheral blood mononuclear cells extracted from an immunocompetent, living human subject. The ADCC process is described in detail in Janeway Jr. C.A. et al., Immunobiology, 5th ed., 2001, Garland Publishing, ISBN 0-8153-3642-X; Pier G.B. et al., Immunology, Infection, and Immunity, 2004, p246-5; Albanell J. et al., Advances in Experimental Medicine and Biology, 2003, 532:p2153-68 and Weng, W.-K. et al., Journal of Clinical Oncology, 2003, 21:p 3940-3947. Suitable methods for the detection and quantification of ADCC can be found in Blomberg et al., Journal of Immunological Methods. 1986, 86:p225-9; Blomberg et al., Journal of Immunological Methods. 1986, 21:92:p17-23 and Patel & Boyd, Journal of Immunological Methods. 1995, 184:p29-38.

ADCC typically involves activation of NK cells and is dependent on the recognition of antibody-coated cells by Fc receptors on the surface of the NK cell. The Fc receptors recognize the
Fc (crystalline) portion of antibodies such as IgG, bound specifically to the surface of a target cell. The Fc receptor that triggers activation of the NK cell is called CD16 or FcyRIIIa. Once the FcyRIIIa receptor is bound to the IgG Fc, the NK cell releases cytokines such as IFN-γ, and cytotoxic granules containing perforin and granzymes that enter the target cell and promote cell death by triggering apoptosis.

The induction of antibody-dependent cellular cytotoxicity (ADCC) by an antibody can be enhanced by modifications that alter interactions between the antibody constant region (Fc) and various receptors that are present on the surface of cells of the immune system. Such modifications include the reduction or absence of alpha, 1,6-linked fucose moieties in the complex oligosaccharide chains that are normally added to the Fc of antibodies during natural or recombinant synthesis in mammalian cells. In a preferred embodiment, non-fucosylated anti-NAALADL2 affinity reagents such as antibodies or fragments thereof are produced for the purpose of enhancing their ability to induce the ADCC response.

Techniques for reducing or ablating alpha, 1,6-linked fucose moieties in the oligosaccharide chains of the Fc are well established. In one example, the recombinant antibody is synthesized in a cell line that is impaired in its ability to add fucose in an alpha, 1,6 linkage to the innermost N-acetylglucosamine of the N-linked biantennary complex-type Fc oligosaccharides. Such cell lines include, but are not limited to, the rat hybridoma YB2/0, which expresses a reduced level of the alpha, 1,6-fucosyltransferase gene, FUT8. Preferably, the antibody is synthesized in a cell line that is incapable of adding alpha, 1,6-linked fucosyl moieties to complex oligosaccharide chains, due to the deletion of both copies of the FUT8 gene. Such cell lines include, but are not limited to, FUT8/-CHO/DG44 cell lines. Techniques for synthesizing partially fucosylated, or non-fucosylated antibodies and affinity reagents are described in Shinkawa et al., J. Biol. Chem. 278:3466-34735 (2003); Yamane-Ohnuki et al., Biotechnology and Bioengineering 87: 614-22 (2004) and in WO00/61739 Al, WO02/31 140 A1 and WO03/085107 Al. In a second example, the iucosylation of a recombinant antibody is reduced or abolished by synthesis in a cell line that has been genetically engineered to overexpress a glycoprotein-modifying glycosyl transferase at a level that maximizes the production of complex N-linked oligosaccharides carrying bisecting N-acetylglucosamine. For example, the antibody is synthesized in a Chinese Hamster Ovary cell line expressing the enzyme N-acetyl glucosamine transferase III (GnT III). Cell lines stably transfected with suitable glycoprotein-modifying glycosyl transferases, and methods of synthesizing antibodies using these cells are described in WO99/54342.

A non-fucosylated antibody or affinity reagent can be used as a therapeutic that is administered alone or in combination with cytokotoxic factor(s) and/or cytokine(s).

In a further modification, the amino acid sequences of the antibody Fc are altered in a way that enhances ADCC activation, without affecting ligand affinity. Examples of such modifications are described in Lazar et al., Proceedings of the National Academy of Sciences 2006, 103: p4005-4010; WO03/074679 and WO2007/039818. In these examples, substitution of amino acids in the antibody Fc, such as aspartate for serine at position 239, and isoleucine for glutamate at position 322, altered the binding affinity of an antibody for Fc receptors, leading to an increase in ADCC activation.

An antibody reagent with enhanced ADCC activation due to amino acid substitutions can be used as a therapeutic that is administered alone or in combination with cytokotoxic factor(s) and/or
cytokine(s).

The invention also provides for bispecific molecules comprising at least one first binding specificity for a first target epitope (i.e. NAALADL2) and a second binding specificity for a second target epitope. The second target epitope maybe present on the same target protein as that bound by the first binding specificity; or the second target epitope may be present of a different target protein to that bound by the first protein to that bound by the first binding specificity. The second target epitope may be present on the same cell as the first target epitope (i.e. NAALADL2); or the second target epitope may be present on a target which is not displayed by the cell which displays the first target epitope. As used herein, the term 'binding specificity' refers to a moiety comprising at least one antibody variable domain.

In one embodiment, the bispecific molecule is a BiTE (bispecific T-cell engager). In particular, the invention provides a bispecific affinity reagent (preferably a bispecific antibody) which comprises a first binding domain for NAALADL2 and a second binding domain for a T-cell antigen, preferably CD3.

These bispecific molecules target NAALADL2 expressing cells to CD3 expressing effector cells (e.g. CD3 expressing cytotoxic T cells) and trigger CD3-mediated effector cell activities, such as T cell clonal expansion and T cell cytotoxicity. The bispecific antibodies of the invention may have a total of either two or three antibody variable domains, wherein first portion of the bispecific antibody is capable of recruiting the activity of a human immune effector cell by specifically binding to an effector antigen located on the human immune effector cell, in which the effector antigen is the human CD3 antigen, said first portion consisting of one antibody variable domain, and a second portion of the bispecific antibody is capable of specifically binding to a target antigen other than the effector antigen e.g. NAALADL2, said target antigen being located on a target cell other than said human immune effector cell, and said second portion comprising one or two antibody variable domains.

In one preferred embodiment, the invention provides a bispecific antibody (preferably a BiTE) which binds to NAALADL2 and CD3 for the treatment of prostate cancer.

**Diagnosis of Cancer Including the diseases of the invention**

According to another aspect of the invention, there is provided a method of detecting, diagnosing and/or screening for or monitoring the progression of cancer e.g. the diseases of the invention or of monitoring the effect of e.g. an anti-cancer drug or therapy directed towards the diseases of the invention in a subject which comprises detecting the presence or level of antibodies capable of immunospecific binding to NAALADL2, or one or more epitope-containing fragments thereof or which comprises detecting a change in the level thereof in said subject.

According to another aspect of the invention there is also provided a method of detecting, diagnosing and/or screening for cancer e.g. the diseases of the invention in a subject which comprises detecting the presence of antibodies capable of immunospecific binding to NAALADL2, or one or more epitope-containing fragments thereof in said subject, in which (a) the presence of an elevated level of antibodies capable of immunospecific binding to NAALADL2 or said one or more epitope-containing fragments thereof in said subject as compared with the level in a healthy subject or (b) the presence of a detectable level of antibodies capable of immunospecific binding to NAALADL2 or said one or more epitope-containing fragments thereof in said subject as compared with a corresponding undetectable level in a healthy subject indicates the presence of said cancer in
said subject.

One particular method of detecting, diagnosing and/or screening for cancer, e.g. the diseases of the invention comprises:

- bringing into contact with a biological sample to be tested NAALADL2, or one or more epitope-containing fragments thereof; and
- detecting the presence of antibodies in the subject capable of immunospecific binding to NAALADL2, or one or more epitope-containing fragments thereof.

According to another aspect of the invention there is provided a method of monitoring the progression of cancer, e.g. the diseases of the invention or of monitoring the effect of e.g. an anti-cancer drug or therapy directed towards the diseases of the invention in a subject which comprises detecting the presence of antibodies capable of immunospecific binding to NAALADL2, or one or more epitope-containing fragments thereof in said subject at a first time point and at a later time point, the presence of an elevated or lowered level of antibodies capable of immunospecific binding to NAALADL2, or one or more epitope-containing fragments thereof in said subject at the later time point as compared with the level in said subject at said first time point, indicating the progression or regression of said cancer, or the effect or non-effect of said anti-cancer drug or therapy in said subject.

The presence of antibodies capable of immunospecific binding to NAALADL2, or one or more epitope-containing fragments thereof is typically detected by analysis of a biological sample obtained from said subject (exemplary biological samples are mentioned above, e.g. the sample is a sample of prostate, bladder, breast, esophagus, head and neck, colorectal, liver, lung, ovarian, gastric, uterus and pancreatic tissue, or else a sample of blood or saliva). The method typically includes the step of obtaining said biological sample for analysis from said subject. The antibodies that may be detected include IgA, IgM and IgG antibodies.

In accordance with the present invention, test samples of e.g. prostate, bladder, breast, esophagus, head and neck, colorectal, liver, lung, ovarian, gastric, uterus or pancreatic tissue, serum, plasma or urine obtained from a subject suspected of having or known to have the diseases of the invention can be used for diagnosis or monitoring. In one embodiment, a change in the abundance of NAALADL2 in a test sample relative to a control sample (from a subject or subjects free from the diseases of the invention) or a previously determined reference range indicates the presence of the diseases of the invention. In another embodiment, the relative abundance of NAALADL2 in a test sample compared to a control sample or a previously determined reference range indicates a subtype of the diseases of the invention (e.g. prostate adenocarcinoma, transitional cell carcinoma, inflammatory breast cancer, familial or sporadic colorectal cancer, squamous cell head and neck carcinoma, hepatocellular carcinoma, squamous cell lung carcinoma, small cell carcinoma, endocrine tumours of the pancreas, ovarian adenocarcinoma, squamous cell esophagus carcinoma and gastric adenocarcinoma). In yet another embodiment, the relative abundance of NAALADL2 in a test sample relative to a control sample or a previously determined reference range indicates the degree or severity of the diseases of the invention (e.g. the likelihood for metastasis). In any of the aforesaid methods, detection of NAALADL2 may optionally be combined with detection of one or more of additional biomarkers for the diseases of the invention. Any suitable method in the art can be employed to measure the level of NAALADL2, including but not limited to the Preferred Technologies described herein, kinase assays, immunoassays to detect and/or visualize the
NAALADL2 (e.g. Western blot, immunoprecipitation followed by sodium dodecyl sulfate polyacrylamide gel electrophoresis, immunocytochemistry, etc.). In a further embodiment, a change in the abundance of mRNA encoding NAALADL2 in a test sample relative to a control sample or a previously determined reference range indicates the presence of the diseases of the invention. Any suitable hybridization assay can be used to detect NAALADL2 expression by detecting and/or visualizing mRNA encoding the NAALADL2 (e.g. Northern assays, dot blots, in situ hybridization, etc.).

In another embodiment of the invention, labeled antibodies (or other affinity reagents), derivatives and analogs thereof, which specifically bind to NAALADL2 can be used for diagnostic purposes to detect, diagnose, or monitor the diseases of the invention. Preferably, the diseases of the invention are detected in an animal, more preferably in a mammal and most preferably in a human.

Screening Assays
The invention provides methods for identifying agents (e.g. candidate compounds or test compounds) that bind to NAALADL2 or have a stimulatory or inhibitory effect on the expression or activity of NAALADL2. The invention also provides methods of identifying agents, candidate compounds or test compounds that bind to a NAALADL2-related polypeptide or a NAALADL2 fusion protein or have a stimulatory or inhibitory effect on the expression or activity of a NAALADL2-related polypeptide or a NAALADL2 fusion protein. Examples of agents, candidate compounds or test compounds include, but are not limited to, nucleic acids (e.g. DNA and RNA), carbohydrates, lipids, proteins, peptides, peptidomimetics, small molecules and other drugs. Agents can be obtained using any of the numerous approaches in combinatorial library methods known in the art, including: biological libraries; spatially addressable parallel solid phase or solution phase libraries; synthetic library methods requiring deconvolution; the "one-bead one-compound" library method; and synthetic library methods using affinity chromatography selection. The biological library approach is limited to peptide libraries, while the other four approaches are applicable to peptide, non-peptide oligomer or small molecule libraries of compounds (Lam, 1997, Anticancer Drug Des. 12:145; U.S. Patent No. 5,738,996; and U.S. Patent No. 5,807,683, each of which is incorporated herein in its entirety by reference).

In one embodiment, agents that interact with (i.e. bind to) NAALADL2, a NAALADL2 fragment (e.g. a functionally active fragment), a NAALADL2-related polypeptide, a fragment of a
NAALADL2-related polypeptide, or a NAALADL2 fusion protein are identified in a cell-based assay system. In accordance with this embodiment, cells expressing NAALADL2, a fragment of a NAALADL2, a NAALADL2-related polypeptide, a fragment of the NAALADL2-related polypeptide, or a NAALADL2 fusion protein are contacted with a candidate compound or a control compound and the ability of the candidate compound to interact with the NAALADL2 is determined. If desired, this assay may be used to screen a plurality (e.g. a library) of candidate compounds. The cell, for example, can be of prokaryotic origin (e.g. *E. coli*) or eukaryotic origin (e.g. yeast or mammalian). Further, the cells can express NAALADL2, a fragment of NAALADL2, a NAALADL2-related polypeptide, a fragment of the NAALADL2-related polypeptide, or a NAALADL2 fusion protein endogenously or be genetically engineered to express NAALADL2, a fragment of NAALADL2, a NAALADL2-related polypeptide, a fragment of the NAALADL2-related polypeptide, or a NAALADL2 fusion protein. In certain instances, NAALADL2, a fragment of NAALADL2, a NAALADL2-related polypeptide, a fragment of the NAALADL2-related polypeptide, or a NAALADL2 fusion protein or the candidate compound is labeled, for example with a radioactive label (such as $^{32}$P, $^{35}$S, and $^{125}$I) or a fluorescent label (such as fluorescein isothiocyanate, rhodamine, phycocerythrin, phycocyanin, allophycocyanin, o-phthalaldehyde or fluorescamine) to enable detection of an interaction between NAALADL2 and a candidate compound. The ability of the candidate compound to interact directly or indirectly with NAALADL2, a fragment of a NAALADL2, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein can be determined by methods known to those of skill in the art. For example, the interaction between a candidate compound and NAALADL2, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein can be determined by flow cytometry, a scintillation assay, immunoprecipitation or western blot analysis.

In another embodiment, agents that interact with (i.e. bind to) NAALADL2, a NAALADL2 fragment (e.g. a functionally active fragment), a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein are identified in a cell-free assay system. In accordance with this embodiment, native or recombinant NAALADL2 or a fragment thereof, or a native or recombinant NAALADL2-related polypeptide or fragment thereof, or a NAALADL2-fusion protein or fragment thereof, is contacted with a candidate compound or a control compound and the ability of the candidate compound to interact with NAALADL2 or NAALADL2-related polypeptide, or NAALADL2 fusion protein is determined. If desired, this assay may be used to screen a plurality (e.g. a library) of candidate compounds. Preferably, NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2-fusion protein is first immobilized. By, for example, contacting NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein with an immobilized antibody (or other affinity reagent) which specifically recognizes and binds it, or by contacting a purified preparation of NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein with a surface designed to bind proteins. NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein may be partially or completely purified (e.g. partially or completely free of other polypeptides) or part of...
a cell lysate. Further, NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, or a fragment of a NAALADL2-related polypeptide may be a fusion protein comprising NAALADL2 or a biologically active portion thereof, or NAALADL2-related polypeptide and a domain such as glutathionine-S-transferase. Alternatively, NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide or a NAALADL2 fusion protein can be biotinylated using techniques well known to those of skill in the art (e.g. biotinylation kit, Pierce Chemicals; Rockford, IL). The ability of the candidate compound to interact with NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein can be determined by methods known to those of skill in the art.

In another embodiment, a cell-based assay system is used to identify agents that bind to or modulate the activity of a protein, such as an enzyme, or a biologically active portion thereof, which is responsible for the production or degradation of NAALADL2 or is responsible for the post-translational modification of NAALADL2. In a primary screen, a plurality (e.g. a library) of compounds are contacted with cells that naturally or recombinantly express: (i) NAALADL2, an isoform of NAALADL2, a NAALADL2 homolog, a NAALADL2-related polypeptide, a NAALADL2 fusion protein, or a biologically active fragment of any of the foregoing; and (ii) a protein that is responsible for processing of NAALADL2, a NAALADL2 isoform, a NAALADL2 homolog, a NAALADL2-related polypeptide, a NAALADL2 fusion protein, or a fragment in order to identify compounds that modulate the production, degradation, or post-translational modification of NAALADL2, a NAALADL2 isoform, a NAALADL2 homolog, a NAALADL2-related polypeptide, a NAALADL2 fusion protein or fragment. If desired, compounds identified in the primary screen can then be assayed in a secondary screen against cells naturally or recombinantly expressing NAALADL2. The ability of the candidate compound to modulate the production, degradation or post-translational modification of NAALADL2, isoform, homolog, NAALADL2-related polypeptide, or NAALADL2 fusion protein can be determined by methods known to those of skill in the art, including without limitation, flow cytometry, a scintillation assay, immunoprecipitation and western blot analysis.

In another embodiment, agents that competitively interact with (i.e. bind to) NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein are identified in a competitive binding assay. In accordance with this embodiment, cells expressing NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein are contacted with a candidate compound and a compound known to interact with NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide or a NAALADL2 fusion protein; the ability of the candidate compound to preferentially interact with NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein is then determined. Alternatively, agents that preferentially interact with (i.e. bind to) NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide or fragment of a NAALADL2-related polypeptide are identified in a cell-free assay system by contacting NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a NAALADL2-related polypeptide, or a NAALADL2 fusion protein with a candidate compound
and a compound known to interact with NAALADL2, a NAALADL2-related polypeptide or a
NAALADL2 fusion protein. As stated above, the ability of the candidate compound to interact
with NAALADL2, a NAALADL2 fragment, a NAALADL2-related polypeptide, a fragment of a
NAALADL2-related polypeptide, or a NAALADL2 fusion protein can be determined by methods
known to those of skill in the art. These assays, whether cell-based or cell-free, can be used to screen
a plurality (e.g. a library) of candidate compounds.

In another embodiment, agents that modulate (i.e. upregulate or downregulate) the
expression or activity of NAALADL2 or a NAALADL2-related polypeptide are identified by
contacting cells (e.g. cells of prokaryotic origin or eukaryotic origin) expressing NAALADL2 or a
NAALADL2-related polypeptide with a candidate compound or a control compound (e.g. phosphate
buffered saline (PBS)) and determining the expression of NAALADL2, NAALADL2-related
polypeptide, or NAALADL2 fusion protein, mRNA encoding NAALADL2, or mRNA encoding the
NAALADL2-related polypeptide. The level of expression of NAALADL2, NAALADL2-related
polypeptide, mRNA encoding NAALADL2, or mRNA encoding the NAALADL2-related
candidate compound is compared to the level of expression of NAALADL2, NAALADL2-related polypeptide, mRNA encoding NAALADL2, or mRNA encoding the NAALADL2-related polypeptide in the presence of the candidate compound (e.g. in the presence of a control compound). The candidate compound can then be identified as a modulator of the expression of NAALADL2, or the NAALADL2-related polypeptide based on this comparison.

For example, when expression of NAALADL2 or mRNA is significantly greater in the presence of the candidate compound than in its absence, the candidate compound is identified as a stimulator of expression of NAALADL2 or mRNA. Alternatively, when expression of NAALADL2 or mRNA is significantly less in the presence of the candidate compound than in its absence, the candidate compound is identified as an inhibitor of the expression of NAALADL2 or mRNA. The level of expression of NAALADL2 or the mRNA that encodes it can be determined by methods known to those of skill in the art. For example, mRNA expression can be assessed by Northern blot analysis or RT-PCR, and protein levels can be assessed by western blot analysis.

In another embodiment, agents that modulate the activity of NAALADL2 or a
NAALADL2-related polypeptide are identified by contacting a preparation containing NAALADL2
or NAALADL2-related polypeptide or cells (e.g. prokaryotic or eukaryotic cells) expressing
NAALADL2 or NAALADL2-related polypeptide with a test compound or a control compound and
determining the ability of the test compound to modulate (e.g. stimulate or inhibit) the activity of
NAALADL2 or NAALADL2-related polypeptide. The activity of NAALADL2 or a
NAALADL2-related polypeptide can be assessed by detecting induction of a cellular signal
transduction pathway of NAALADL2 or NAALADL2-related polypeptide (e.g. intracellular Ca\textsuperscript{2+},
diacylglycerol, IP3, etc.), detecting catalytic or enzymatic activity of the target on a suitable
substrate, detecting the induction of a reporter gene (e.g. a regulatory element that is responsive to
NAALADL2 or a NAALADL2-related polypeptide and is operably linked to a nucleic acid
encoding a detectable marker, e.g. luciferase), or detecting a cellular response, for example, cellular
differentiation, or cell proliferation. Based on the present description, techniques known to those of
skill in the art can be used for measuring these activities (see, e.g. U.S. Patent No. 5,401,639, which
is incorporated herein by reference). The candidate compound can then be identified as a modulator of the activity of NAALADL2 or a NAALADL2-related polypeptide by comparing the effects of the
candidate compound to the control compound. Suitable control compounds include phosphate buffered saline (PBS) and normal saline (NS).

In another embodiment, agents that modulate (i.e. upregulate or downregulate) the expression, activity or both the expression and activity of NAALADL2 or a NAALADL2-related polypeptide are identified in an animal model. Examples of suitable animals include, but are not limited to, mice, rats, rabbits, monkeys, guinea pigs, dogs and cats. Preferably, the animal used represent a model of the diseases of the invention (e.g. xenografts of prostate cancer cell lines such as LNCaP, PC-3, and DU-145, xenografts of bladder cancer cell lines such as UCRU-BL-12, UCRU-BL-13 and UCRU-BL-14, Russell et al. Cancer Res. 1986 Apr;46(4 Pt 2):2035-40, xenografts of breast cancer cell lines such as MCF-7 (Ozzello L, Sordat M., Eur J Cancer. 1980;16:553-559) and MCF10AT (Miller et al., J Natl Cancer Inst. 1993;85:1725-1732) in nude or SCID mice, xenografts of human colorectal cancer cell lines such as MDA-MB-345 in oestrogen-deprived SCID mice, (Eccles et al. 1994 Cell Biophysics 24/25, 279), xenografts of head and neck cancer cell lines such as FaDu and HNX-0E, xenografts of liver cancer cell lines such as MHCC97 in nude mice, Tian et al., Br J. Cancer 1999 Nov;81(5):814-21, xenografts of non small cell lung cancer cell lines such as A549 and H460, xenografts of small cell lung cancer cell lines such as NCI-H345, xenografts of pancreatic cancer cell lines such as MIA PaCa-2 in nude mice, Marincola et al., J Surg Res 1989 Dec;47(6):520-9, xenografts of gastric cancer cell lines such as NCI-N87 in nude mice and xenografts of ovarian cancer cell lines such as OVCAR3 in nude mice, Ulla K. NÄssander et al., CANCER RESEARCH 52, 646-653. February 1. 1992). These can be utilized to test compounds that modulate NAALADL2 levels, since the pathology exhibited in these models is similar to that of e.g. the diseases of the invention. In accordance with this embodiment, the test compound or a control compound is administered (e.g. orally, rectally or parenterally such as intraperitoneally or intravenously) to a suitable animal and the effect on the expression, activity or both expression and activity of NAALADL2 or NAALADL2-related polypeptide is determined. Changes in the expression of NAALADL2 or a NAALADL2-related polypeptide can be assessed by the methods outlined above.

In yet another embodiment, NAALADL2 or a NAALADL2-related polypeptide is used as a "bait protein" in a two-hybrid assay or three hybrid assay to identify other proteins that bind to or interact with NAALADL2 or a NAALADL2-related polypeptide (see, e.g. U.S. Patent No. 5,283,317; Zervos et al. (1993) Cell 72:223-232; Madura et al. (1993) J. Biol. Chem. 268:12046-12054; Barrel et al. (1993) BioTechniques 14:920-924; Iwabuchi et al. (1993) Oncogene 8:1693-1696; and PCT Publication No. WO 94/10300). As those skilled in the art will appreciate, such binding proteins are also likely to be involved in the propagation of signals by NAALADL2 as, for example, upstream or downstream elements of a signaling pathway involving NAALADL2.

This invention further provides novel agents identified by the above-described screening assays and uses thereof for treatments as described herein. In addition, the invention also provides the use of an agent which interacts with, or modulates the activity of, NAALADL2 in the manufacture of a medicament for the treatment of the diseases of the invention.

**Therapeutic Use of NAALADL2**

The invention provides for treatment or prevention of various diseases and disorders by administration of a therapeutic compound. Such compounds include but are not limited to: NAALADL2, NAALADL2 analogs, NAALADL2-related polypeptides and derivatives and variants
(including fragments) thereof; antibodies (or other affinity reagents) to the foregoing; nucleic acids encoding NAALADL2, NAALADL2 analogs, NAALADL2-related polypeptides and fragments thereof; antisense nucleic acids to a gene encoding NAALADL2 or a NAALADL2-related polypeptide; and modulator (e.g. agonists and antagonists) of a gene encoding NAALADL2 or a NAALADL2-related polypeptide. An important feature of the present invention is the identification of genes encoding NAALADL2 involved in cancers such as the diseases of the invention. The diseases of the invention, for example, can be treated (e.g. to ameliorate symptoms or to retard onset or progression) or prevented by administration of a therapeutic compound that reduces function or expression of NAALADL2 in the serum or tissue of subjects having the diseases of the invention.

In one embodiment, one or more antibodies (or other affinity reagents) each specifically binding to NAALADL2 are administered alone or in combination with one or more additional therapeutic compounds or treatments.

A biological product such as an antibody (or other affinity reagent) is allogeneic to the subject to which it is administered. In one embodiment, a human NAALADL2 or a human NAALADL2-related polypeptide, a nucleotide sequence encoding a human NAALADL2 or a human NAALADL2-related polypeptide, or an antibody (or other affinity reagent) to a human NAALADL2 or a human NAALADL2-related polypeptide, is administered to a human subject for therapy (e.g. to ameliorate symptoms or to retard onset or progression) or prophylaxis.

Treatment And Prevention Of The diseases of the invention

The diseases of the invention, for example, are treated or prevented by administration to a subject suspected of having or known to have one or more of the diseases of the invention or to be at risk of developing one or more of the diseases of the invention of a compound that modulates (i.e. increases or decreases) the level or activity (i.e. function) of NAALADL2 that is differentially present in the serum or tissue of subjects having one or more of the diseases of the invention compared with serum or tissue of subjects free from the diseases of the invention. In one embodiment, the diseases of the invention are treated or prevented by administering to a subject suspected of having or known to have one or more of the diseases of the invention or to be at risk of developing the diseases of the invention a compound that upregulates (i.e. decreases) the level or activity (i.e. function) of NAALADL2 that is increased in the serum or tissue of subjects having one or more of the diseases of the invention. Examples of such a compound include, but are not limited to, NAALADL2 antisense oligonucleotides, ribozymes, antibodies (or other affinity reagents) directed against NAALADL2, and compounds that inhibit the enzymatic activity of NAALADL2.

Other useful compounds e.g. NAALADL2 antagonists and small molecule NAALADL2 antagonists, can be identified using in vitro assays.

Cancer, e.g. the diseases of the invention, may also be treated or prevented by administration to a subject suspected of having or known to have such cancer, or to be at risk of developing such
cancer, of a compound that downregulates the level or activity (i.e. function) of NAALADL2 that are increased in the serum or tissue of subjects having such cancer. Examples of such a compound include but are not limited to: NAALADL2, NAALADL2 fragments and NAALADL2-related polypeptides; nucleic acids encoding NAALADL2, a NAALADL2 fragment and a NAALADL2-related polypeptide (e.g. for use in gene therapy); and, for those NAALADL2 or NAALADL2-related polypeptides with enzymatic activity, compounds or molecules known to modulate that enzymatic activity. Other compounds that can be used, e.g. NAALADL2 agonists, can be identified using in *in vitro* assays.

In another embodiment, therapy or prophylaxis is tailored to the needs of an individual subject. Thus, in specific embodiments, compounds that promote the level or function of NAALADL2 are therapeutically or prophylactically administered to a subject suspected of having or known to have cancer e.g. the diseases of the invention, in whom the levels or functions of NAALADL2 are absent or are decreased relative to a control or normal reference range. In further embodiments, compounds that promote the level or function of NAALADL2 are therapeutically or prophylactically administered to a subject suspected of having or known to have cancer e.g. the diseases of the invention in whom the levels or functions of NAALADL2 are increased relative to a control or to a reference range. In further embodiments, compounds that decrease the level or function of NAALADL2 are therapeutically or prophylactically administered to a subject suspected of having or known to have cancer e.g. the diseases of the invention in whom the levels or functions of NAALADL2 are increased relative to a control or to a reference range. The change in NAALADL2 function or level due to the administration of such compounds can be readily detected, e.g. by obtaining a sample (e.g. blood or urine) and assaying *in vitro* the levels or activities of NAALADL2, or the levels of mRNAs encoding NAALADL2, or any combination of the foregoing. Such assays can be performed before and after the administration of the compound as described herein.

The compounds of the invention include but are not limited to any compound, e.g. a small organic molecule, protein, peptide, antibody (or other affinity reagent), nucleic acid, etc. that restores the NAALADL2 profile towards normal. The compounds of the invention may be given in combination with any other chemotherapy drugs.

**Vaccine Therapy**

Another aspect of the invention is an immunogenic composition, suitably a vaccine composition, comprising NAALADL2 or an epitope containing fragment thereof, or nucleic acid encoding NAALADL2 or a fragment thereof optionally together with an immunostimulant. There is also provided a method of raising an immune response which comprises administering to a subject such compositions and a method for treating or preventing cancer e.g. the diseases of the invention which comprises administering to a subject in need thereof a therapeutically effective amount of such compositions and such compositions for use in preventing or treating the diseases of the invention.

Thus, NAALADL2 may be useful as antigenic material, and may be used in the production of vaccines for treatment or prophylaxis of cancer, e.g. the diseases of the invention. Such material
can be "antigenic" and/or "immunogenic". Generally, "antigenic" is taken to mean that the protein is capable of being used to raise antibodies (or other affinity reagents) or indeed is capable of inducing an antibody response in a subject or experimental animal. "Immunogenic" is taken to mean that the protein is capable of eliciting an immune response such as a protective immune response in a subject or experimental animal. Thus, in the latter case, the protein may be capable of not only generating an antibody response but, in addition, non-antibody based immune responses. "Immunogenic" also embraces whether the protein may elicit an immune-like response in an in-vitro setting e.g. a T-cell proliferation assay. The generation of an appropriate immune response may require the presence of one or more adjuvants and/or appropriate presentation of an antigen.

The skilled person will appreciate that homologues or derivatives of NAALADL2 will also find use as antigenic/immunogenic material. Thus, for instance proteins which include one or more additions, deletions, substitutions or the like are encompassed by the present invention. In addition, it may be possible to replace one amino acid with another of similar "type", for instance, replacing one hydrophobic amino acid with another. One can use a program such as the CLUSTAL program to compare amino acid sequences. This program compares amino acid sequences and finds the optimal alignment by inserting spaces in either sequence as appropriate. It is possible to calculate amino acid identity or similarity (identity plus conservation of amino acid type) for an optimal alignment. A program like BLASTx will align the longest stretch of similar sequences and assign a value to the fit. It is thus possible to obtain a comparison where several regions of similarity are found, each having a different score. Both types of analysis are contemplated in the present invention.

In the case of homologues and derivatives, the degree of identity with a protein as described herein is less important than that the homologue or derivative should retain its antigenicity and/or immunogenicity. However, suitably, homologues or derivatives having at least 60% similarity (as discussed above) with the proteins or polypeptides described herein are provided, for example, homologues or derivatives having at least 70% similarity, such as at least 80% similarity are provided. Particularly, homologues or derivatives having at least 90% or even 95% similarity are provided. Suitably, homologues or derivatives have at least 60% sequence identity with the proteins or polypeptides described herein. Preferably, homologues or derivatives have at least 70% identity, more preferably at least 80% identity. Most preferably, homologues or derivatives have at least 90% or even 95% identity.

In an alternative approach, the homologues or derivatives could be fusion proteins, incorporating moieties which render purification easier, for example by effectively tagging the desired protein or polypeptide. It may be necessary to remove the "tag" or it may be the case that the fusion protein itself retains sufficient antigenicity to be useful.

It is well known that it is possible to screen an antigenic protein or polypeptide to identify epitopic regions, i.e. those regions which are responsible for the protein or polypeptide's antigenicity or immunogenicity. Methods well known to the skilled person can be used to test fragments and/or homologues and/or derivatives for antigenicity. Thus, the fragments of the present invention should include one or more such epitopic regions or be sufficiently similar to such regions to retain their antigenic/immunogenic properties. Thus, for fragments according to the present invention the degree of identity is perhaps irrelevant, since they may be 100% identical to a particular part of a protein or
polypeptide, homologue or derivative as described herein. The key issue, once again, is that the
fragment retains the antigenic/immunogenic properties of the protein from which it is derived.
What is important for homologues, derivatives and fragments is that they possess at least a
degree of the antigenicity/immunogenicity of the protein or polypeptide from which they are
derived. Thus, in an additional aspect of the invention, there is provided antigenic/or immunogenic
fragments of NAALADL2, or of homologues or derivatives thereof.
NAALADL2, or antigenic fragments thereof, can be provided alone, as a purified or isolated
preparation. They may be provided as part of a mixture with one or more other proteins of the
invention, or antigenic fragments thereof. In a further aspect, therefore, the invention provides an
antigen composition comprising NAALADL2 and/or one or more antigenic fragments thereof. Such
a composition can be used for the detection and/or diagnosis of cancer, e.g. the diseases of the
invention.
Vaccine compositions according to the invention may be either a prophylactic or therapeutic
vaccine composition.
The vaccine compositions of the invention can include one or more adjuvants
(immunostimulants). Examples well-known in the art include inorganic gels, such as aluminium
hydroxide, and water-in-oil emulsions, such as incomplete Freund’s adjuvant. Other useful
adjuvants will be well known to the skilled person.
Suitable adjuvants for use in vaccine compositions for the treatment of cancer include: 3De-
O-acylated monophosphoryl lipid A (known as 3D-MPL or simply MPL see WO92/1 16556), a
saponin, for example QS21 or QS7, and TLR4 agonists such as a CpG containing molecule, for
example as disclosed in WO95/26204. The adjuvants employed may be a combination of
components, for example MPL and QS21 or MPL, QS21 and a CpG containing moiety. Adjuvants
may be formulated as oil-in-water emulsions or liposomal formulations. Such preparations may
include other vehicles.
In another embodiment, a preparation of oligonucleotides comprising 10 or more
consecutive nucleotides complementary to a nucleotide sequence encoding NAALADL2 or a
NAALADL2 peptide fragments is used as vaccines for the treatment of cancer, e.g. the diseases of
the invention. Such preparations may include adjuvants or other vehicles.
Inhibition Of NAALADL2 To Treat The diseases of the invention
In one embodiment of the invention, cancer, e.g. the diseases of the invention is treated or
prevented by administration of a compound that antagonizes (inhibits) the level and/or function of
NAALADL2 which is elevated in the serum or tissue of subjects having such cancer as compared
with serum or tissue of subjects free from such cancer.
Compounds useful for this purpose include but are not limited to anti-NAALADL2
antibodies (or other affinity reagents, and fragments and derivatives containing the binding region
thereof), NAALADL2 antisense or ribozyme nucleic acids, and nucleic acids encoding
dysfunctional NAALADL2 that may be used to "knockout" endogenous NAALADL2 function by
homologous recombination (see, e.g. Capecchi, 1989, Science 244:1288-1292). Other compounds
that inhibit NAALADL2 function can be identified by use of known in vitro assays, e.g. assays for
the ability of a test compound to inhibit binding of NAALADL2 to another protein or a binding
partner, or to inhibit a known NAALADL2 function.
Such inhibition may, for example, be assayed in vitro or in cell culture, but genetic assays
may also be employed. The Preferred Technologies can also be used to detect levels of
NAALADL2 before and after the administration of the compound. Suitable in vitro or in vivo assays
are utilized to determine the effect of a specific compound and whether its administration is
indicated for treatment of the affected tissue, as described in more detail below.

In a specific embodiment, a compound that inhibits NAALADL2 function (activity) is
administered therapeutically or prophylactically to a subject in whom an increased serum or tissue
level or functional activity of NAALADL2 (e.g. greater than the normal level or desired level) is
detected as compared with serum or tissue of subjects with e.g. the diseases of the invention who do
not receive treatment according to the invention or to bring the level or activity to that found in
subjects free from such cancer, or a predetermined reference range. Methods standard in the art can
be employed to measure the increase in NAALADL2 level or function, as outlined above. Suitable
NAALADL2 inhibitor compositions may, for example, include small molecules, i.e. molecules of
1000 daltons or less. Such small molecules can be identified by the screening methods described
herein.

**Assays for Therapeutic or Prophylactic Compounds**

The present invention also provides assays for use in drug discovery in order to identify or
verify the efficacy of compounds for treatment or prevention of cancers expressing NAALADL2,
e.g. the diseases of the invention.

Thus there is provided a method of screening for compounds that modulate the activity of
NAALADL2, the method comprising: (a) contacting NAALADL2 or a biologically active portion
thereof with a candidate compound; and (b) determining whether activity of NAALADL2 is thereby
modulated. Such a process may comprise (a) contacting NAALADL2 or a biologically active
portion thereof with a candidate compound in a sample; and (b) comparing the activity of
NAALADL2 or a biologically active portion thereof in said sample after contact with said candidate
compound with the activity of NAALADL2 or a biologically active portion thereof in said sample
before contact with said candidate compound, or with a reference level of activity.

The method of screening may be a method of screening for compounds that inhibit activity
of NAALADL2.

NAALADL2 or a biologically active portion thereof may, for example be expressed on or
by a cell. NAALADL2 or a biologically active portion thereof may, for example, be isolated from
cells which express it. NAALADL2 or a biologically active portion thereof may, for example, be
immobilised onto a solid phase.

There is also provided a method of screening for compounds that modulate the expression of
NAALADL2 or nucleic acid encoding NAALADL2, the method comprising: (a) contacting cells
expressing NAALADL2 or nucleic acid encoding NAALADL2 with a candidate compound; and (b)
determining whether expression of NAALADL2 or nucleic acid encoding NAALADL2 is thereby
modulated. Such a process may comprises (a) contacting cells expressing NAALADL2 or nucleic
acid encoding NAALADL2 with a candidate compound in a sample; and (b) comparing the
expression of NAALADL2 or nucleic acid encoding NAALADL2 by cells in said sample after
contact with said candidate compound with the expression of NAALADL2 or nucleic acid encoding
NAALADL2 of cells in said sample before contact with said candidate compound, or with a
reference level of expression.

The method may be a method of screening for compounds that inhibit expression of
NAALADL2 or nucleic acid encoding NAALADL2.

Other aspects of the invention include: a compound obtainable by an aforementioned screening method, a compound which modulates the activity or expression of NAALADL2 or nucleic acid encoding NAALADL2, for example a compound which inhibits the activity or expression of NAALADL2 or nucleic acid encoding NAALADL2.

Such a compound is provided for use in treating or preventing cancer, e.g. the diseases of the invention. There is also provided a method for treating or preventing cancer, e.g. the diseases of the invention which comprises administering to a subject in need thereof a therapeutically effective amount of such a compound.

Test compounds can be assayed for their ability to restore NAALADL2 levels in a subject having e.g. the diseases of the invention towards levels found in subjects free from such cancers or to produce similar changes in experimental animal models of such cancers. Compounds able to restore NAALADL2 levels in a subject having e.g. the diseases of the invention towards levels found in subjects free from such cancers or to produce similar changes in experimental animal models of such cancers can be used as lead compounds for further drug discovery, or used therapeutically. NAALADL2 expression can be assayed by the Preferred Technologies, immunoassays, gel electrophoresis followed by visualization, detection of NAALADL2 activity, or any other method taught herein or known to those skilled in the art. Such assays can be used to screen candidate drugs, in clinical monitoring or in drug development, where abundance of

NAALADL2 can serve as a surrogate marker for clinical disease.

In various specific embodiments, in vitro assays can be carried out with cells representative of cell types involved in a subject's disorder, to determine if a compound has a desired effect upon such cell types.

Compounds for use in therapy can be tested in suitable animal model systems prior to testing in humans, including but not limited to rats, mice, chicken, cows, monkeys, rabbits, etc. For in vivo testing, prior to administration to humans, any animal model system known in the art may be used. Examples of animal models of the diseases of the invention include, but are not limited to xenografts of prostate cancer cell lines such as LNCaP, PC-3, and DU-145, xenografts of bladder cancer cell lines such as UCRU-BL-12, UCRU-BL-13 and UCRU-BL-14, Russell et al. Cancer Res. 1986 Apr;46(4 Pt 2):2035-40, xenografts of breast cancer cell lines such as MCF-7 (Ozzello L., Sordat M., Eur J Cancer. 1980;16:553-559) and MCF10AT (Miller et al., J Natl Cancer Inst. 1993;85:1725-1732) in nude or SCID mice, xenografts of human colorectal cancer cell lines such as MDA-MB-345 in oestrogen-deprived SCID mice, (Eccles et al. 1994 Cell Biophysics 24/25, 279), xenografts of head and neck cancer cell lines such as FaDu and HNX-OE, xenografts of liver cancer cell lines such as MHCC97 in nude mice, Tian et al., Br J. Cancer 1999 Nov;81(5):814-21, xenografts of non small cell lung cancer cell lines such as A549 and H460, xenografts of small cell lung cancer cell lines such as NCI-H345, xenografts of pancreatic cancer cell lines such as MIA PaCa-2 in nude mice, Marincola et al., J Surg Res 1989 Dec;47(6):520-9, xenografts of gastric cancer cell lines such as NCI-N87 in nude mice and xenografts of ovarian cancer cell lines such as OVCAR3 in nude mice, Ulla K. Nässander et al., CANCER RESEARCH 52, 646-653. February 1. 1992. These can be utilized to test compounds that modulate NAALADL2 levels, since the pathology exhibited in these models is similar to that of e.g. the diseases of the invention. It is also apparent to the skilled artisan that based upon the present disclosure, transgenic animals can be produced with "knock-out"
mutations of the gene or genes encoding NAALADL2. A "knock-out" mutation of a gene is a mutation that causes the mutated gene to not be expressed, or expressed in an aberrant form or at a low level, such that the activity associated with the gene product is nearly or entirely absent. Preferably, the transgenic animal is a mammal; more preferably, the transgenic animal is a mouse.

In one embodiment, test compounds that modulate the expression of NAALADL2 are identified in non-human animals (e.g. mice, rats, monkeys, rabbits, and guinea pigs), preferably non-human animal models for the diseases of the invention expressing NAALADL2. In accordance with this embodiment, a test compound or a control compound is administered to the animals, and the effect of the test compound on expression of NAALADL2 is determined. A test compound that alters the expression of NAALADL2 can be identified by comparing the level of NAALADL2 (or mRNA encoding the same) in an animal or group of animals treated with a test compound with the level of NAALADL2 or mRNA in an animal or group of animals treated with a control compound. Techniques known to those of skill in the art can be used to determine the mRNA and protein levels, for example, in situ hybridization. The animals may or may not be sacrificed to assay the effects of a test compound.

In another embodiment, test compounds that modulate the activity of NAALADL2 or a biologically active portion thereof are identified in non-human animals (e.g. mice, rats, monkeys, rabbits, and guinea pigs), preferably non-human animal models for the diseases of the invention expressing NAALADL2. In accordance with this embodiment, a test compound or a control compound is administered to the animals, and the effect of a test compound on the activity of NAALADL2 is determined. A test compound that alters the activity of NAALADL2 can be identified by assaying animals treated with a control compound and animals treated with the test compound. The activity of NAALADL2 can be assessed by detecting induction of a cellular second messenger of NAALADL2 (e.g. intracellular Ca\(^{2+}\), diacylglycerol, IP3, etc.), detecting catalytic or enzymatic activity of NAALADL2 or binding partner thereof, detecting the induction of a reporter gene (e.g. a regulatory element that is responsive to NAALADL2 operably linked to a nucleic acid encoding a detectable marker, such as luciferase or green fluorescent protein), or detecting a cellular response (e.g. cellular differentiation or cell proliferation). Techniques known to those of skill in the art can be utilized to detect changes in the activity of NAALADL2 (see, e.g. U.S. Patent No. 5,401,639, which is incorporated herein by reference).

In yet another embodiment, test compounds that modulate the level or expression of NAALADL2 are identified in human subjects having e.g. the diseases of the invention, preferably those having e.g. severe the diseases of the invention. In accordance with this embodiment, a test compound or a control compound is administered to the human subject, and the effect of a test compound on NAALADL2 expression is determined by analyzing the expression of NAALADL2 or the mRNA encoding the same in a biological sample (e.g. serum, plasma, or urine). A test compound that alters the expression of NAALADL2 can be identified by comparing the level of NAALADL2 or mRNA encoding the same in a subject or group of subjects treated with a control compound to that in a subject or group of subjects treated with a test compound. Alternatively, alterations in the expression of NAALADL2 can be identified by comparing the level of NAALADL2 or mRNA encoding the same in a subject or group of subjects before and after the administration of a test compound. Techniques known to those of skill in the art can be used to obtain the biological sample and analyze the mRNA or protein expression. For example, the
Preferred Technologies described herein can be used to assess changes in the level of NAALADL2.

In another embodiment, test compounds that modulate the activity of NAALADL2 are identified in human subjects having e.g. the diseases of the invention (preferably those with e.g. severe the diseases of the invention). In this embodiment, a test compound or a control compound is administered to the human subject, and the effect of a test compound on the activity of NAALADL2 is determined. A test compound that alters the activity of NAALADL2 can be identified by comparing biological samples from subjects treated with a control compound to samples from subjects treated with the test compound. Alternatively, alterations in the activity of NAALADL2 can be identified by comparing the activity of NAALADL2 in a subject or group of subjects before and after the administration of a test compound. The activity of NAALADL2 can be assessed by detecting in a biological sample (e.g. serum, plasma, or urine) induction of a cellular signal transduction pathway of NAALADL2 (e.g. intracellular Ca^{2+}, diacylglycerol, IP3, etc.), catalytic or enzymatic activity of NAALADL2 or a binding partner thereof, or a cellular response, for example, cellular differentiation, or cell proliferation. Techniques known to those of skill in the art can be used to detect changes in the induction of a second messenger of NAALADL2 or changes in a cellular response. For example, RT-PCR can be used to detect changes in the induction of a cellular second messenger.

In another embodiment, a test compound that changes the level or expression of NAALADL2 towards levels detected in control subjects (e.g. humans free from e.g. the diseases of the invention) is selected for further testing or therapeutic use. In another embodiment, a test compound that changes the activity of NAALADL2 towards the activity found in control subjects (e.g. humans free from e.g. the diseases of the invention) is selected for further testing or therapeutic use.

In another embodiment, test compounds that reduce the severity of one or more symptoms associated with e.g. the diseases of the invention are identified in human subjects having e.g. the diseases of the invention, preferably subjects with e.g. severe the diseases of the invention. In accordance with this embodiment, a test compound or a control compound is administered to the subjects, and the effect of a test compound on one or more symptoms of e.g. the diseases of the invention is determined. A test compound that reduces one or more symptoms can be identified by comparing the subjects treated with a control compound to the subjects treated with the test compound. Techniques known to physicians familiar with e.g. the diseases of the invention can be used to determine whether a test compound reduces one or more symptoms associated with e.g. the diseases of the invention. For example, a test compound that reduces tumour burden in a subject having e.g. the diseases of the invention will be beneficial for such subject.

In another embodiment, a test compound that reduces the severity of one or more symptoms associated with cancer, e.g. the diseases of the invention is selected for further testing or therapeutic use.

**Therapeutic and Prophylactic Compositions and their Use**

The invention provides methods of treatment (and prophylaxis) comprising administering to a subject an effective amount of a compound of the invention (e.g. NAALADL2 protein, an affinity reagent capable of specific binding to NAALADL2 or a fragment thereof, or a nucleic acid encoding NAALADL2). In a particular aspect, the compound is substantially purified (e.g. substantially free from substances that limit its effect or produce undesired side-effects).
Formulations and methods of administration that can be employed when the compound comprises a nucleic acid are described above; additional appropriate formulations and routes of administration are described below.

Various delivery systems are known and can be used to administer a compound of the invention, e.g. encapsulation in liposomes, microparticles, microcapsules, recombinant cells capable of expressing the compound, receptor-mediated endocytosis (see, e.g. Wu and Wu, 1987, *J. Biol. Chem.* 262:4429-4432), construction of a nucleic acid as part of a retroviral or other vector, etc. Methods of introduction can be enteral or parenteral and include but are not limited to intradermal, intramuscular, intraperitoneal, intravenous, subcutaneous, intranasal, epidural, and oral routes. The compounds may be administered by any convenient route, for example by infusion or bolus injection, by absorption through epithelial or mucocutaneous linings (e.g. oral mucosa, rectal and intestinal mucosa, etc.) and may be administered together with other biologically active agents. Administration can be systemic or local. In addition, it may be desirable to introduce the pharmaceutical compositions of the invention into the central nervous system by any suitable route, including intraventricular and intrathecal injection; intraventricular injection may be facilitated by an intraventricular catheter, for example, attached to a reservoir, such as an Ommaya reservoir. Pulmonary administration can also be employed, e.g. by use of an inhaler or nebulizer, and formulation with an aerosolizing agent.

In one aspect of the invention a nucleic acid employed in the invention may be delivered to the dermis, for example employing particle mediated epidermal delivery.

In a specific embodiment, it may be desirable to administer the pharmaceutical compositions of the invention locally to the area in need of treatment; this may be achieved, for example, and not by way of limitation, by local infusion during surgery, topical application, e.g. by injection, by means of a catheter, or by means of an implant, said implant being of a porous, non-porous, or gelatinous material, including membranes, such as sialastic membranes, or fibers. In one embodiment, administration can be by direct injection into e.g. prostate, bladder, breast, esophagus, head and neck, colorectal, liver, lung, ovarian, gastric, uterus and pancreatic tissue or at the site (or former site) of a malignant tumor or neoplastic or pre-neoplastic tissue.

In another embodiment, the compound can be delivered in a vesicle, in particular a liposome (see Langer, 1990, *Science* 249:1527-1533; Treat *et al.*, in Liposomes in the Therapy of Infectious Disease and Cancer, Lopez-Berestein and Fidler (eds.), Liss, New York, pp. 353-365 (1989); Lopez-Berestein, *ibid.*, pp. 317-327; see generally *ibid.*)

In a specific embodiment where the compound of the invention is a nucleic acid encoding a protein, the nucleic acid can be administered in vivo to promote expression of its encoded protein, by constructing it as part of an appropriate nucleic acid expression vector and administering it so that it becomes intracellular, e.g. by use of a retroviral vector (see U.S. Patent No. 4,980,286), or by direct injection, or by use of microparticle bombardment (e.g. a gene gun; Biolistic, Dupont), or coating with lipids or cell-surface receptors or transfecting agents, or by administering it in linkage to a homebox-like peptide which is known to enter the nucleus (see e.g. Joliot et al., 1991, Proc. Natl. Acad. Set USA 88:1864-1868), etc. Alternatively, a nucleic acid can be introduced intracellularly and incorporated within host cell DNA for expression, by homologous recombination.

The present invention also provides pharmaceutical compositions. Such compositions comprise a therapeutically effective amount of a compound of the invention, and a pharmaceutically acceptable carrier. In a specific embodiment, the term "pharmaceutically acceptable" means suitable for approval by a regulatory agency of the Federal or a state government or listed in the U.S. Pharmacopeia or other generally recognized pharmacopeia for use in animals, and more particularly in humans. The term "carrier" refers to a diluent, adjuvant, excipient, or vehicle with which the therapeutic is administered. Such pharmaceutical carriers can be sterile liquids, such as water and oils, including those of petroleum, animal, vegetable or synthetic origin, such as peanut oil, soybean oil, mineral oil, sesame oil and the like. Water is a preferred carrier when the pharmaceutical composition is administered intravenously. Saline solutions and aqueous dextrose and glycerol solutions can also be employed as liquid carriers, particularly for injectable solutions. Suitable pharmaceutical excipients include starch, glucose, lactose, sucrose, gelatin, malt, rice, flour, chalk, silica gel, sodium stearate, glycerol monostearate, talc, sodium chloride, dried skim milk, glycerol, propylene, glycol, water, ethanol and the like. The composition, if desired, can also contain minor amounts of wetting or emulsifying agents, or pH buffering agents. These compositions can take the form of solutions, suspensions, emulsion, tablets, pills, capsules, powders, sustained-release formulations and the like. The composition can be formulated as a suppository, with traditional binders and carriers such as triglycerides. Oral formulation can include standard carriers such as pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, magnesium carbonate, etc. Examples of suitable pharmaceutical carriers are described in "Remington's Pharmaceutical Sciences" by E.W. Martin. Such compositions will contain a therapeutically effective amount of the compound, for example in purified form, together with a suitable amount of carrier so as to provide the form for proper administration to the subject. The formulation should suit the mode of administration.

In one embodiment, for example where one or more antibodies are employed, the composition is formulated in accordance with routine procedures as a pharmaceutical composition adapted for intravenous administration to human beings. Typically, compositions for intravenous administration are solutions in sterile isotonic aqueous buffer. Where necessary, the composition may also include a solubilizing agent and a local anesthetic such as lidocaine to ease pain at the site of the injection. Generally, the ingredients are supplied either separately or mixed together in unit dosage form, for example, as a dry lyophilized powder or water free concentrate in a hermetically sealed container such as an ampoule or sachette indicating the quantity of active agent. Where the
composition is to be administered by infusion, it can be dispensed with an infusion bottle containing sterile pharmaceutical grade water or saline. Where the composition is administered by injection, an ampoule of sterile water for injection or saline can be provided so that the ingredients may be mixed prior to administration.

The compounds of the invention can be formulated as neutral or salt forms. Pharmaceutically acceptable salts, where appropriate, include those formed with free amino groups such as those derived from hydrochloric, phosphoric, acetic, oxalic, tartaric acids, etc., and those formed with free carboxyl groups such as those derived from sodium, potassium, ammonium, calcium, ferric hydroxides, isopropylamine, triethylamine, 2-ethylamino ethanol, histidine, procaine, etc.

The amount of the compound of the invention which will be effective in the treatment of cancer, for example, the diseases of the invention can be determined by standard clinical techniques. In addition, in vitro assays may optionally be employed to help identify optimal dosage ranges. The precise dose to be employed in the formulation will also depend on the route of administration, and the seriousness of the disease or disorder, and should be decided according to the judgment of the practitioner and each subject's circumstances. However, suitable dosage ranges for intravenous administration are generally about 20-500 micrograms of active compound per kilogram body weight. Suitable dosage ranges for intranasal administration are generally about 0.01 pg/kg body weight to 1 mg/kg body weight. Effective doses may be extrapolated from dose-response curves derived from in vitro or animal model test systems.

Suppositories generally contain active ingredient in the range of 0.5% to 10% by weight; oral formulations preferably contain 10% to 95% active ingredient.

The invention also provides a pharmaceutical pack or kit comprising one or more containers filled with one or more of the ingredients of the pharmaceutical compositions of the invention. Optionally associated with such container(s) can be a notice in the form prescribed by a governmental agency regulating the manufacture, use or sale of pharmaceuticals or biological products, which notice reflects (a) approval by the agency of manufacture, use or sale for human administration, (b) directions for use, or both.

Thus in one aspect the kit comprises antibodies employed in the invention, for example the antibodies may be lyophilized for reconstitution before administration or use. Where the kit is for use in therapy/treatment such as cancer the antibody or antibodies may be reconstituted with an isotonic aqueous solution, which may optionally be provided with the kit. In one aspect the kit may comprise a polypeptide such as an immunogenic polypeptide employed in the invention, which may for example be lyophilized. The latter kit may further comprise an adjuvant for reconstituting the immunogenic polypeptide.

The invention also extends to a composition as described herein for example a pharmaceutical composition and/or vaccine composition for use in inducing an immune response in a subject.

In yet a further embodiment, the invention provides a medicament comprising, separately or together:

(a) an affinity reagents which binds to NAALADL2, and

(b) an anti-cancer agent or other active agent,

for simultaneous, sequential or separate administration in the treatment of cancer, preferably in the
treatment of one of the diseases of the invention.

Determination of Abundance of NAALADL2 by Imaging Technology

An advantage of determining abundance of NAALADL2 by imaging technology may be that such a method is non-invasive (save that reagents may need to be administered) and there is no need to extract a sample from the subject.

Suitable imaging technologies include positron emission tomography (PET) and single photon emission computed tomography (SPECT). Visualisation of NAALADL2 using such techniques requires incorporation or binding of a suitable label e.g. a radiotracer such as $^{18}$F, $^{11}$C or $^{123}$I (see e.g. NeuroRx - The Journal of the American Society for Experimental NeuroTherapeutics (2005) 2(2), 348-360 and idem pages 361-371 for further details of the techniques). Radiotracers or other labels may be incorporated into NAALADL2 by administration to the subject (e.g. by injection) of a suitably labelled specific ligand. Alternatively they may be incorporated into a binding affinity reagent (e.g. antibody) specific for NAALADL2 which may be administered to the subject (e.g. by injection). For discussion of use of Affibodies for imaging see e.g. Orlova A, Magnusson M, Eriksson TL, Nilsson M, Larsson B, Hoiden-Guthenberg I, Widstrom C, Carlsson J, Tolmachev V, Stahl S, Nilsson FY, Tumor imaging using a picomolar affinity HER2 binding Affibody molecule, Cancer Res. 2006 Apr 15;66(8):4339-48.

Diagnosis And Treatment Of Cancer Including The diseases of the invention Using Immunohistochemistry

Immunohistochemistry is an excellent detection technique and may therefore be very useful in the diagnosis and treatment of cancer, including the diseases of the invention. Immunohistochemistry may be used to detect, diagnose, or monitor cancers such as those mentioned above, through the localization of NAALADL2 antigens in tissue sections by the use of labeled antibodies (or other affinity reagents), derivatives and analogs thereof, which specifically bind to NAALADL2, as specific reagents through antigen-antibody interactions that are visualized by a marker such as fluorescent dye, enzyme, radioactive element or colloidal gold.

The advancement of monoclonal antibody technology has been of great significance in assuring the place of immunohistochemistry in the modern accurate microscopic diagnosis of human neoplasms. The identification of disseminated neoplastically transformed cells by immunohistochemistry allows for a clearer picture of cancer invasion and metastasis, as well as the evolution of the tumour cell associated immunophenotype towards increased malignancy. Future antineoplastic therapeutical approaches may include a variety of individualized immunotherapies, specific for the particular immunophenotypical pattern associated with each individual patient's neoplastic disease. For further discussion see e.g. Bodey B, The significance of immunohistochemistry in the diagnosis and therapy of neoplasms, Expert Opin Biol Ther. 2002 Apr; 2(4):371-93.

Preferred features of each aspect of the invention are as for each of the other aspects mutatis mutandis. The prior art documents mentioned herein are incorporated to the fullest extent permitted by law.

The invention is illustrated by the following non-limiting examples.
EXAMPLE 1: IDENTIFICATION OF NAALADL2 EXPRESSED IN PROSTATE CANCER, BREAST CANCER, COLORECTAL CANCER, GASTRIC CANCER AND PANCREATIC CANCER TISSUE SAMPLES USING LIQUID CHROMATOGRAPHY-MASS SPECTROMETRY (LC/MS)

Using the following protocol, membrane proteins extracted from prostate cancer, breast cancer, colorectal cancer, gastric cancer and pancreatic cancer tissue and corresponding normal or normal adjacent tissue (NAT) samples were digested and resulting peptides sequenced by tandem mass spectrometry.

1.1 MATERIALS AND METHODS

1.1.1 Plasma Membrane Fractionation

The cells recovered from a prostate cancer, breast cancer, colorectal cancer, gastric cancer and pancreatic cancer or a normal or normal adjacent tissue were homogenised and submitted to centrifugation at 1000 x g. The supernatant was taken and ultra-centrifuged at 49500 x g. The resulting pellet was re-homogenized and separated by discontinuous sucrose density centrifugation. After ultra-centrifugation at 107000 x g, the fractions at the phase boundary were recovered and pelleted.

1.1.2 Plasma membrane solubilisation

Plasma membrane fractions were resuspended in SDS (Sodium dodecyl sulfate) to give a final SDS concentration of 0.5%, centrifuged and the solubilized protein extracted.

1.1.3 Trypsinolysis

For in-solution digestion, the volume of a 50μg protein solution was made up to 100μl using 200mM ammonium bicarbonate. 10μl of the reducing agent DL-Dithiothreitol (75mM) was added to the sample and incubated at 80°C for 15 minutes. This was followed by a cysteine blocking step using 10μl of 150mM iodoacetamide and incubation in the dark for 30 minutes at room temperature. The SDS concentration was then diluted to 0.05% with the addition of ultra-pure water. A sufficient volume of trypsin (Promega V5111) was added to the mixture allowing for 1μg of trypsin to 2.75μg of protein and incubated overnight at 37°C.

Alternatively, 105μg of protein solutions were reduced using 3μl of 50mM TCEP and incubating at 60°C for 1 hour. The sample was then processed on the FASP filtration devices of the Protein Digestion Kit (Protein Discovery) according to the manufacturer’s instructions, but using triethylammonium bicarbonate instead of ammonium bicarbonate. Trypsinolysis was performed in a final volume of 75μl, using 1μg of trypsin to 50μg of protein.

1.1.4 Peptide fractionation

The digested protein samples were dried under a vacuum, re-suspended in 0.1% aqueous formic acid and trifluoroacetic acid (TFA) was added to reduce the pH of the solution to <3. Peptides were separated by ion exchange using an Agilent Zorbax Bio-Strong Cation Exchange series II column on an Agilent LC1 200 Series liquid chromatography system. Alternatively, the Agilent 3100 OFFGEL Fractionator and the OFFGEL Kit pH 3 - 10 was used for pI-based separation, according to the protocol of the supplier. Following re-hydration of the IPG strips, equal volumes of a membrane digest were loaded into each well. Following separation, the resulting fractions were acidified.
1.1.5 Mass spectrometry

Fractionated samples were analysed by liquid chromatography-mass spectrometry using a Waters nanoACQUITY UPLC System fitted with a nanoACQUITY UPLC BEH 130 C18 column, 75 μm x 250mm (186003545) and a LTQ Orbitrap Velos (Thermo Fisher Scientific). Peptides were eluted with a 300nl/min gradient increasing from 3% to 35% acetonitrile over 120 min. Full-scan mass spectra were acquired at 60000 resolving power between 400-2000 m/z mass range in the Orbitrap. In each cycle, the twenty most intense peptides were selected for CID MS/MS scans in the linear ion trap with nanospray ion source fitted on the instrument.

1.1.6 Amino acid sequence analysis of peptide

The raw data generated from the LTQ Orbitrap Velos was processed through the Mascot software (Matrix Science) which uses the Mowse algorithm (Curr Biol. 1993 Jun;3(6):327-3) to infer amino acids sequences from the peak lists by searching against a sequence database consisting of Ensembl (http://www.ensembl.org/index.html), IPI (www.ebi.ac.uk/IPI/IPIhuman.html) and SwissProt (http://www.uniprot.org) along with contaminant protein sequences. Criteria for peptide identification included trypsin digestion, up to 2 missed cleavage sites and various biological and chemical modifications (oxidized methionine, cysteine modification by MMTS or iodoacetamide and phosphorylation of serine, threonine and tyrosine). Peptides ranked 1 with an expectation value of 0.05% or less, an ion score of 28 or higher were loaded into our OGAP database where they were processed into protein groups.

1.1.7 Discrimination of prostate cancer, breast cancer, colorectal cancer, gastric cancer and pancreatic cancer associated proteins

The process to identify NAALDL2 used the peptide sequences obtained experimentally by mass spectrometry, as described above, of naturally occurring human proteins to identify and organize coding exons in the published human genome sequence. These experimentally determined sequences indicated in Table 1, were compared with the OGAP® database which was compiled by processing and integration of peptide masses, peptide signatures, ESTs and Public Domain Genomic Sequence Data as described in International Patent Application WO2009/087462.

Table 1. NAALDL2 Specific Peptides Identified By LC/MS in the plasma membranes of prostate cancer, breast cancer, colorectal cancer, gastric cancer and pancreatic cancer tissue samples.

1.1.8 Protein Index

The protein index is a measure of both protein prevalence and peptide abundance. The algorithm takes into account both the number of samples in which the protein has been observed and the number of peptides observed vs observable peptides from each sample. The resulting value is then graded by pairwise comparison of corresponding normal samples vs cancer samples.

1.2 RESULTS

These experiments identified NAALADL2 as further described herein. The full-length NAALADL2 was detected in the plasma membrane of prostate cancer, breast cancer, colorectal cancer, gastric cancer and pancreatic cancer tissue samples. Table 2 shows the expression distribution of NAALADL2 measured by the protein index. Expression of NAALADL2 in these cancer tissues indicates NAALADL2 is a valuable therapeutic and diagnostic target in these cancers.

EXAMPLE 2: IMMUNOHISTOCHEMISTRY USING ANTIBODY TO NAALADL2

Using the following Reference Protocol, immunohistochemistry was performed on FFPE tumor and normal tissues using a goat polyclonal antibody to NAALADL2 (R&D Systems, UK).

2.1 MATERIALS AND METHODS

2.1.1 Materials

EnVision plus kits (K4006 and K4010) were from DAKO, CA, USA.
EZ-De-Wax was from BioGenex, CA, USA.
Tissue sections and arrays were from Biomax, MD, USA.

2.1.2 Deparaffinisation and Rehydration

Slides were heated for 2 h at 60°C in 50ml Falcons in a water bath with no buffer. Each Falcon tube had one slide or two slides back-to-back with a long gel loading tip between them to prevent slides from sticking.Slides were deparaffinised in EZ-DeWax for 5 min in a black slide rack, then rinsed with 1 ml of the same DeWax solution, followed by a distilled water wash. Slides
were placed in a coplin jar filled with water; the water was changed twice.

2.1.3 Antigen Retrieval (Microwave)

Water was exchanged for antigen retrieval solution = 1 x citrate buffer, pH 6 (DAKO).

Antigen was retrieved by the microwave method. The slides in the plastic coplin jar in antigen retrieval solution were placed into an 800W microwave which was then heated on full power until antigen retrieval solution was boiling. The antigen retrieval solution was then left to simmer on low power for a further 10 mins, after which the plastic coplin jar was removed from the microwave and left to cool to room temperature for another 20 min. The lid was opened and samples taken out to rest on the bench. The slides were washed 1x5min with PBS-3T (0.5 L PBS + 3 drops of Tween-20) and the slides were placed in PBS.

2.1.4 Antigen Retrieval (Pressure cooker)

Water was exchanged for antigen retrieval solution = 1 x citrate buffer, pH 6 (DAKO).

Antigen was retrieved by the pressure cooker method. The slides in the plastic coplin jar in antigen retrieval solution were placed into a pressure cooker which was then heated up to position 6 (Russell Hobbs 13407 Hob Electric Two Boiling Ring, Model 13407), 15-20 min into the incubation, the temperature was reduced to position 3 and left at that (when the temperature inside the pressure cooker was 117°C) for another 20-25 min. Then the hob was switched off and the cooker was placed onto the cold hob and the pressure was released by carefully moving the handle into the position between "open" and "closed". The whole system was left to release the pressure and to cool down for another 20 min. The lid was opened and samples taken out to rest on the bench. The slides were washed 1 x 5 min with PBS-3T (0.5 L PBS + 3 drops of Tween-20) and the slides were placed in PBS.

2.1.4 Tissue staining

Endogenous peroxide blockade was performed using solution supplied with EnVision+ kits. The slide was taken out of the coplin jar and the PBS around tissues was wiped. Excess PBS on top of tissue was removed by tipping the slide on one side and soaking wipes in drop of PBS accumulating at the edge of the tissue section. Peroxide solution was dropped to cover the whole tissue. 1-4 drops was enough to cover even large sections. When all samples were covered with peroxide block, the time was set to 5 min. The slides were rinsed with water from wash bottle and then 1 x 5 min with PBS-3T, 1 x 5 min with PBS. They were then left in coplin jar in PBS. The primary antibody was diluted with an Antibody diluent reagent (DAKO) to 2g/ml. Excess PBS was wiped from slides, excess PBS from tissue sections was removed as above. 50-200μl of diluted primary antibody was applied to each section and/or tissue microarray; taking care to cover the whole tissue. The slide was gently tapped to distribute the antibody evenly over the section or a pipette tip was used over the top of the section. The slide was incubated for 45 min in moist chamber at room temperature. The antibody was rinsed off with PBS from wash bottle and the slides were mounted in the Shandon Coverplate system. Air bubbles between the slide and plastic coverplate were prevented by placing the coverplate into the coplin jar filled with PBS and gently sliding the slide with tissue sections into the coverplate. The slide was pulled out of the coplin jar at the same time holding it tightly together with the coverplate. The assembled slide was placed into the rack, letting PBS trapped in the funnel and between the slide and coverplate to run through. Slides were washed with 2 x 2ml (or 4 x 1ml) PBS-3T, 1 x 2ml PBS. The corresponding peroxidase polymer was applied 2 x 2 drops per slide and incubated for 35 min at room temperature. The slides were
washed as above. The DAB substrate was made up in dilution buffer; 2ml containing 2 drops of substrate was enough for 10 slides. The DAB reagent was applied to the slides by applying a few drops at a time. All of the DAB was distributed between the slides. The slides were incubated for 10 min. The slides were washed 1 x 2ml with PBS-3T, 1 x 2ml (or 2 x 1ml) with PBS, waiting until all PBS had gone through the slide. Hematoxylin (DAKO) was applied; 1ml was enough for 10 slides and slides were incubated for 1 min at room temperature. Funnels were filled with 2ml of water and let to run through. When slides were clear of the excess of hematoxylin, the system was disassembled; tissue sections and/or arrays were washed with water from the wash bottle and placed into black slide rack. EZ-DeWax for 5 min; then 95% ethanol for 2-5 min. Slides were left to dry then mounted in mounting media and covered with coverslip.

2.2 Results

Immunohistochemical analysis revealed specific staining of tumor cells in prostate cancer, bladder cancer, breast cancer, esophagus cancer, head and neck cancer, colorectal cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer and uterus cancer. At high magnification it was evident that most of the cells were heavily stained in the plasma membrane. Thus antibodies directed to NAALADL2 may have utility as therapeutics and diagnostics in these cancers and other cancer types showing expression of NAALADL2.

Example 3: T cell activation and specific lysis of NAALADL2 expressing cells

Background:

In order to assess the possibility of a target being amenable to a BiTE approach (bisppecific antibody fragment combining anti-CD3 binding epitope combined with a binding site for a specific antigen on a target cell or tissue), an assay was developed to test T cell activation with anti-CD3 and a monoclonal antibody specific for a target antigen of interest.

Methods:

For this assay NAALADL2 is expressed on LnCAP cells. The cells were counted, centrifuged at 800 xg, resuspended in assay media (dye free RPMI + 10% ultralow lg FBS - Invitrogen catalog #16250078) at 0.12 million cells per ml. 6,000 cells (50 ul) was added to each appropriate well of a 96 well flat bottom tissue culture plate. The plate was previously coated overnight with goat anti-mouse kappa from Southern Biotech (catalog # 1050-01) at 3 ug/ml in PBS. The excess antibody solution was removed from the plates prior to adding the LnCAP cells. Human CD8+ T cells (frozen) were purchased from AllCells catalog number PB009-3F. The T cells were thawed and washed according to manufacturer’s directions. Cells were resuspended at 1,500,000 cells per ml in assay media. The T cells were added to the LnCAP cells in the 96 well anti-kappa coated plate at 150,000 cells per well. The NAALADL2 antibody (R&D catalog # MAB4665) was added to the appropriate wells at 4.3 ug/ml or 1.4 ug/ml. Functional grade anti-CD3 clone OKT3 (eBioscience catalog number 16-0037-85) was added to the appropriate wells at 4.3 or 1.4 ug/ml. Control wells received no antibody. The plate was incubated for 24 hours in a 5% C02, humidified tissue culture incubator at 37 degrees.

50 ul of supernatant from each well was transferred to a 96 well flat bottom plate. The media was analyzed for LDH according to the manufacturer’s directions on the CytoTox 96® Non-Radioactive Cytotoxicity (Cat #G1780) and read at OD 490 nmon a visible plate reader. The ODs
for the replicate were averaged and used to calculate the % lysis. Maximum lysis was determined using provided detergent and lysing wells plated with 6000 LnCAP cells at the same time the assay was plated. The maximum lysis supernatant OD was 2.1. Spontaneous lysis was determined using the no antibody wells (T cells + LnCAP cells with no added anti-CD3 or anti-NAALDL2 monoclonal antibody).

Results:

Figure 1 shows the specific lysis of LnCAP cells by anti-NAALDL2 monoclonal antibodies and that cell death was proportional to antibody concentration. Thus Anti-NAALDL2 monoclonal antibodies are able to induce T-cell cytotoxicity via activation by CD3.

CLAIMS:

1. A method for the treatment or prophylaxis of prostate cancer wherein NAALADL2 is expressed in said prostate cancer, which comprises administering to a subject in need thereof a therapeutically effective amount of a bispecific antibody which binds to NAALADL2 and CD3.

2. A method for the treatment or prophylaxis of cancer wherein NAALADL2 is expressed in said cancer, which comprises administering to a subject in need thereof a therapeutically effective amount of an affinity reagent which binds to NAALADL2.

3. The method according to claim 2, for the treatment or prophylaxis of a cancer selected from the group consisting of prostate cancer, bladder cancer, breast cancer, esophagus cancer, head and neck cancer, colorectal cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer, uterus cancer and pancreatic cancer.

4. The method according to claim 2 or 3, wherein the affinity reagent binds specifically to NAALADL2.

5. The method according to any one of claims 2 to 4, wherein the affinity reagent is an antibody or a functional fragment thereof or an antibody mimetic.

6. The method according to claim 5, wherein the affinity reagent is a monoclonal antibody or an antigen-binding fragment thereof.

7. The method according to claim 5 or 6, wherein the affinity reagent is a chimeric antibody, a human antibody, a humanized antibody, a single chain antibody, a defucosylated antibody or a bispecific antibody (preferably a BiTE).

8. The method according to claim 5, wherein:
   (a) the functional antibody fragment is a UniBody, a domain antibody or a Nanobody; or
   (b) the antibody mimetic is an Affibody, a DARPin, an Anticalin, an Avimer, a Versabody or a Duocalin.

9. The method according to any one of claims 2 to 8, wherein the affinity reagent contains or is conjugated to a therapeutic moiety.

10. The method according to claim 9, wherein the therapeutic moiety is a cytotoxic moiety or a radioactive isotope.

11. The method according to claim 9 or 10, wherein the affinity reagent is an antibody drug conjugate.
12. The method according to any one of claims 1 to 8 wherein the affinity reagent elicits antibody-dependent cellular cytotoxicity (ADCC).

13. The method according to any one of claims 1 to 8 wherein the affinity reagent elicits complement dependent cytotoxicity (CDC).

14. The method according to any one of claims 1 to 8 wherein the affinity reagent elicits T-cell cytotoxicity.

15. The method according to any one of claims 1 to 8 wherein the affinity reagent induces apoptosis of cancer cells, kills or reduces the number of cancer stem cells and/or kills or reduces the number of circulating cancer cells.

16. A method of detecting, diagnosing and/or screening for or monitoring the progression cancer wherein NAALADL2 is expressed in said cancer, or of monitoring the effect of a cancer drug or therapy wherein NAALADL2 is expressed in said cancer, in a subject which comprises detecting the presence or level of NAALADL2, or one or more fragments thereof, or the presence or level of nucleic acid encoding NAALADL2 or which comprises detecting a change in the level thereof in said subject.

17. The method according to claim 16 which comprises detecting the presence of NAALADL2, or one or more fragments thereof, or the presence of nucleic acid encoding NAALADL2, in which either (a) the presence of an elevated level of NAALADL2 or said one or more fragments thereof or an elevated level of nucleic acid encoding NAALADL2 in the subject as compared with the level in a healthy subject, or (b) the presence of a detectable level of NAALADL2 or said one or more fragments thereof or a detectable level of nucleic acid encoding NAALADL2 in the subject as compared with a corresponding undetectable level in a healthy subject is indicative of the presence of cancer wherein NAALADL2 is expressed in said cancer, in said subject.

18. A method of detecting, diagnosing and/or screening for or monitoring the progression cancer wherein NAALADL2 is expressed in said cancer, or of monitoring the effect of a cancer drug or therapy wherein NAALADL2 is expressed in said cancer, in a subject which comprises detecting the presence or level of antibodies capable of immunospecific binding to NAALADL2, or one or more fragments thereof.

19. The method according to any one of claims 16 to 18 wherein the presence of NAALADL2, or one or more fragments thereof, or the presence of nucleic acid encoding NAALADL2, or the presence or level of antibodies capable of immunospecific binding to NAALADL2, or one or more fragments thereof, is detected by analysis of a biological sample obtained from the subject.
20. The method according to any one of claims 16 to 19 wherein the presence of NAALADL2, or one or more fragments thereof, is detected using an affinity reagent which binds to NAALADL2.

21. The method according to claim 20 wherein the affinity reagent is as defined in any one of claims 3 to 8.

22. The method according to claim 20 or 21 wherein the affinity reagent contains or is conjugated to a detectable label.

23. The method according to any one of claims 16 to 22, wherein the cancer is selected from the group consisting of prostate cancer, bladder cancer, breast cancer, esophagus cancer, head and neck cancer, colorectal cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer, uterus cancer and pancreatic cancer.

24. The method according to any one of claims 1 to 23 wherein the subject is a human.

25. A method for identifying an agent for the treatment or prophylaxis of cancer wherein NAALADL2 is expressed in said cancer, wherein the method comprises (a) contacting NAALADL2, or one or more fragments thereof, with a candidate agent; and (b) determining whether the agent binds to NAALADL2, or one or more fragments thereof.

26. The method according to claim 25 further comprising the step of testing the ability of an agent which binds to NAALADL2, or one or more fragments thereof, to inhibit cancer wherein NAALADL2 is expressed in said cancer.

27. The method according to claims 25 or 26 wherein the affinity reagent modulates a physiological function of NAALADL2, inhibits ligand binding to NAALADL2 and/or inhibits a signal transduction pathway mediated by NAALADL2.

28. The method according to any one of claims 25 to 27, wherein the cancer is selected from the group consisting of prostate cancer, bladder cancer, breast cancer, esophagus cancer, head and neck cancer, colorectal cancer, liver cancer, lung cancer, ovarian cancer, gastric cancer, uterus cancer and pancreatic cancer.

**INTERNATIONAL SEARCH REPORT**

**Box No. II  Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)**

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.: because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

**Box No. III  Observations where unity of invention is lacking (Continuation of item 3 of first sheet)**

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☑ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. ☑ As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of additional fees.

3. ☑ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

   1-15 (completely) ; 24(partially)

4. ☑ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.

**Remark on Protest**

- ☑ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.

- ☑ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.

- ☑ No protest accompanied the payment of additional search fees.
This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: 1 (completely) ; 2-15, 24 (partially)
   A bi-specific antibody which binds NAALADL2 and CD3 for use in the treatment of prostate cancer

2. claims: 2-15, 24 (all partially)
   An affinity reagent which binds to NAALADL2 for use in the treatment of cancer

3. claims: 16, 17 (completely) ; 19-24 (partially)
   A method of detecting, diagnosing and/or screening for or monitoring the progress of cancer wherein NAALADL2 is expressed in said cancer, or of monitoring the effect of a cancer drug or therapy on a NAALADL2-expressing cancer by detecting the presence or level or change in level of NAALADL2 protein or nucleic acid

4. claims: 18 (completely) ; 19-24 (partially)
   A method of detecting, diagnosing and/or screening for or monitoring the progress of cancer wherein NAALADL2 is expressed in said cancer, or of monitoring the effect of a cancer drug or therapy on a NAALADL2-expressing cancer by detecting the presence or level of antibodies capable of immunospecific binding to NAALADL2 protein

5. claims: 25-28
   A method of identifying an agent for the treatment or prophylaxis of NAALADL2-expressing cancer by contacting NAALADL2 with a candidate agent and determining whether the agent binds to NAALADL2
