(54) Title: MULTI-AXIS RELATIVE POSITIONING STAGE

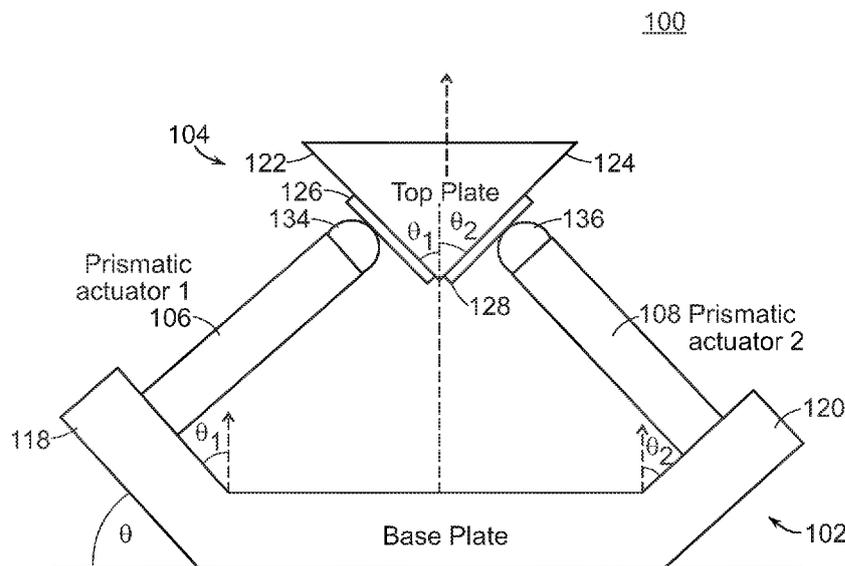

FIG. 2

(57) Abstract: A parallel position manipulator includes a top plate, a baseplate and a plurality of prismatic joint actuators. Each actuator includes an actuator joint having five Degrees of Freedom (DOF) at either the base plate or the top plate. When one or more of the actuators extends or contracts, the pivot points, or five DOF actuator joint, of the remaining actuators are allowed to shift in any axis other than that actuator's primary axis of motion.

**(84) Designated States** (*unless otherwise indicated, for every kind of regional protection available*): ARIPO (BW, GH, GM, KE, LR, LS, MW, MZ, NA, RW, SD, SL, ST, SZ, TZ, UG, ZM, ZW), Eurasian (AM, AZ, BY, KG, KZ, RU, TJ, TM), European (AL, AT, BE, BG, CH, CY, CZ, DE, DK, EE, ES, FI, FR, GB, GR, HR, HU, IE, IS, IT, LT, LU, LV, MC, MK, MT, NL, NO, PL, PT, RO, RS, SE, SI, SK, SM, TR), OAPI (BF, BJ, CF, CG, CI, CM, GA, GN, GQ, GW, KM, ML, MR, NE, SN, TD, TG).

## MULTI-AXIS RELATIVE POSITIONING STAGE

### RELATED APPLICATIONS

[0001] This application claims benefit of U.S. Provisional Application No.62/402,674, filed on September 30, 2016, and entitled MULTI-AXIS RELATIVE POSITIONING STAGE, which is hereby incorporated by reference in its entirety.

### FIELD OF INTEREST

[0002] Inventive concepts relate to a positioning stage and, in particular, to a multi-axis relative positioning stage.

### BACKGROUND

[0003] Position manipulators are employed in a vast array of applications to position objects, tool, or instruments with varying degrees of precision. A survey of kinematic joints, or kinematic pairs, that may be used in position manipulators are illustrated in Fig. 1, including: rigid (no motion), prismatic, revolute, parallel cylinders, cylindrical, spherical, planar, edge slider, cylindrical slider, point slider, spherical slider, and crossed cylinder.

[0004] The Stewart Platform (also referred to herein as a hexapod) is a multi-axis positioning stage made up of six actuators with spherical, ball, or universal joints at both ends of each actuator, for example. Hexapods are considered the world class multi-axis positioning stage design for most applications, but are often cost-prohibitive. One problem with hexapods is that it is a synergistic motion platform because of the mutual interaction of the actuators. That is, due to the mutual interaction of the actuators, none of the actuators can be moved independently; a given move requires many or all of the actuators to move different specific amounts and at different speed profiles to prevent the stage from binding. Additionally, these motion and speed profiles change continuously as the defined starting and ending points are changed. For this reason, a highly complex computer algorithm is required to individually calculate the distance to travel and speed profiles necessary for each actuator to get the top plate of the stage from point A to point B, even if a short distance single axis

move is desired. As a result, a human operator is incapable of manually performing, even this simple move, without binding the stage.

[0005] Another significant disadvantage with a hexapod is that the stiffness of the joints (against off axis motion) dictates the “slop,” or “play,” and, therefore, the resolution of the stage. This is a design conflict because it is exponentially more difficult to make spherical joints (employed in hexapods) at tighter and tighter tolerances. That is, in the case where a designer makes a world class spherical bearing to maximize stage resolution and minimize slop, he has, by default, exacerbated two inherent issues. First, because of the rigidity of the spherical joints, the accuracy of the motion and speed profile requirements for each actuator increases exponentially to prevent binding. Second, the capability requirements of the actuators increases exponentially in order to achieve the required precision motions and speed profiles. As a result, improving the resolution of a hexapod requires an exponential increase in computing power for determining motion and speed profiles, an exponential increase in the performance capabilities of the actuators, and twelve high quality spherical bearings. All of these factors drive up the cost of a hexapod significantly.

[0006] Although hexapods typically cost from three to ten times as much as their kinematic chain counterpart, they are often preferred because they do not suffer from tolerance stack up issues. Ten microns of precision is not an uncommon positioner requirement for many applications and, for example, in the photonics industry, submicron precision is often required. At this date, hexapods typically cost from \$60,000 to greater than \$120,000, each depending on physical size, load limits, and precision requirements. An alternative precise position manipulator would be highly desirable.

#### SUMMARY

[0007] In accordance with principles of inventive concepts, a parallel position manipulator includes a top plate, a base plate (also referred to herein as a bottom plate or baseplate) and three, four, five or six prismatic joint actuators. Each actuator includes an actuator joint having five Degrees of Freedom (DOF) at either the base plate or the top plate. In operation, when one or more of the actuators extends or contracts the pivot points, e.g., five DOF actuator joints, of the remaining actuators are allowed to shift in any axis other than that actuator's axis of motion (that is, an axis defined by the actuator's extension and contraction). In example embodiments, magnetic force, gravity, and/or a pliable polymer,

such as silicone, may be employed to keep the up to five DOF pivot points in contact with their respective (that is, top or bottom) plate in a contact region when the prismatic actuators are extended or retracted. In example embodiments at least two of the prismatic actuators are perpendicular to at least two other prismatic actuators. If a fifth axis is added, its associated prismatic actuator is arranged perpendicular to the other four prismatic actuators.

[0008] In example embodiments the actuators may be any of several types, such as: piezo actuators, manual micrometer screws, magnetic actuators, stepper motors with linear actuators (either integral or separate), hydraulic cylinders, pneumatic cylinders, or rotary motors with eccentric cams, for example. In example embodiments in accordance with principles of inventive concepts, the parallel position manipulator is configured such that the push and pull forces exerted by each actuator is greater than the shear friction of all the other actuators combined. In example embodiments this is accomplished by employing materials that have a high holding force but a low shear force, for example, such as a hard metal spherical surface magnetically held in contact with a hard flat metal surface. In such embodiments only one of the sides (that is, either the hard metal spherical surface or the hard flat metal surface) is magnetized, because if both sides are magnetic they will be semi-constrained in the sliding axis and, therefore, behave like a spherical three DOF joint.

[0009] In accordance with principles of inventive concepts, a positioning stage includes a plurality of magnetic prismatic joint actuators, a base plate and a top plate. The top plate may support a device for precise positioning thereof. The top plate may be supported by a plurality of magnetic prismatic joint actuators, which are, in turn, supported by the base plate. In example embodiments, each actuator is fixed to a portion of the baseplate, which positions each actuator at an angle to the horizontal. In example embodiments, the angle is forty-five degrees, which thereby positions actuators on opposite ends, or endpieces of the baseplate and ninety degrees to one another. In example embodiments, sides of the top plate are formed at the same angle to the horizontal as sides of the baseplate, although other configurations are contemplated within the scope of inventive concepts. Magnets are provided on the angled sides of the top plate. Each actuator includes, at its distal end, a magnetic material, which may be a ferrous metal, for example. In example embodiments, the magnetic material is in the shape of a hemisphere, but other shapes and combinations are contemplated within the scope of inventive concepts. In preferred embodiments, each magnetic material end is configured to contact a magnet on a side of the top plate to thereby support the top plate above the baseplate.

[0010] In operation, an actuator distal end is held in contact with a magnet on a side of the top plate through force of the magnet. As an actuator is activated (that is, extended or retracted), the top plate moves linearly in the direction of motion determined by the motion of the actuator. The distal end of an actuator in contact with a magnet on the opposite side of the top plate remains in contact with the magnet, through the magnetic force of the magnet operating upon the magnetic material of the actuator's distal end. At the same time, the distal end of this actuator allows the magnet (and top plate) to slide in a direction dictated by the motion of the activated actuator.

[0011] In accordance with the inventive concepts, provided is a parallel positioner, comprising a top plate, a baseplate, and three or more actuators configured to support the top plate over the baseplate and to move the top plate in response to extension or retraction of one or more actuators, wherein each of the actuators includes a joint having five degrees of freedom.

[0012] In various embodiments, each of the actuators includes a magnetic joint as a five degree of freedom joint.

[0013] In various embodiments, the top plate includes angled sides and the actuators are configured to extend from the baseplate to the top plate and to support the top plate along the angled sides of the top plate.

[0014] In various embodiments, in a neutral position, the angled sides of the top plate are at the same angle to the horizontal as the angled sides of the baseplate.

[0015] In various embodiments, each magnetic joint includes an end of an actuator formed of a hemispherical magnetic material and a magnet in a contacting region of a plate.

[0016] In various embodiments, each magnetic joint is formed on a side of the top plate, each respective actuator end forming the joint is configured to contact a magnet on the side of the top plate and each respective opposing end of the actuator is configured to be fixedly attached to the baseplate.

[0017] In various embodiments, the parallel positioner includes four prismatic actuators each forming magnetic joints with sides of the top plate, two actuators per side, and each prismatic actuator fixed to the baseplate at the other end, wherein endpieces of the baseplate and sides of the top plate, when in a neutral position, are formed at the same angle to the horizontal.

[0018] In various embodiments, the actuators are configured such that the same amount of extension or retraction of any pair of actuators produces movement of the top plate

solely along a single axis, and said extension or retraction is carried out under control of an electronic controller.

[0019] In accordance with another aspect of the inventive concept, provided is a method of positioning a device, comprising providing a top plate upon which the device rests, providing a baseplate to support the top plate, and providing three or more actuators between the top plate and baseplate, the actuators configured to support the top plate over the baseplate and moving the top plate by extension or retraction of one or more actuators, wherein each of the actuators includes a joint having five degrees of freedom.

[0020] In various embodiments, each of the actuators includes a magnetic joint as a five degree of freedom joint.

[0021] In various embodiments, the top plate includes angled sides and the actuators are configured to extend from the baseplate to the top plate and to support the top plate along angled sides of the top plate.

[0022] In various embodiments, in a neutral position, the angled sides of the top plate are at the same angle to the horizontal as angled sides of the baseplate.

[0023] In various embodiments, each magnetic joint includes an end of an actuator formed of a hemispherical magnetic material and a magnet in a contacting region of a plate.

[0024] In various embodiments, each magnetic joint is formed on a side of the top plate, each respective actuator end of the joint is configured to contact a magnet on the side of the top plate and each respective opposing end of the actuator is configured to be fixedly attached to the baseplate.

[0025] In various embodiments, the method of positioning includes providing four prismatic actuators each forming magnetic joints with sides of the top plate, two actuators per side, and each prismatic actuator fixed to the baseplate at the other end, wherein endpieces of the baseplate and sides of the top plate, when in a neutral position, are formed at the same angle to the horizontal.

[0026] In various embodiments, the actuators are configured such that the same amount of extension or retraction of any pair of actuators produces movement of the top plate solely along a single axis and said extension or retraction is carried out under control of an electronic controller.

[0027] In accordance with another aspect of the inventive concept, provided is a photonic positioning device, comprising a photonic device, a top plate supporting the photonic device, a baseplate, and three or more actuators configured to support the top plate

over the baseplate and to move the top plate in response to extension or retraction of one or more actuators, wherein each of the actuators includes a joint having five degrees of freedom.

[0028] In various embodiments, the photonic device is an optical fiber splicer.

[0029] In various embodiments, the photonic positioning device further comprises four prismatic actuators each forming magnetic joints with sides of the top plate, two actuators per side, and each prismatic actuator fixed to the baseplate at the other end, wherein endpieces of the baseplate and sides of the top plate, when in a neutral position, are formed at the same angle to the horizontal.

[0030] In various embodiments, the actuators are configured such that the same amount of extension or retraction of any pair of actuators produces movement of the top plate solely along a single axis, and said extension or retraction is carried out under control of an electronic controller.

[0031] In accordance with another aspect of the inventive concepts, provided is a parallel positioner, comprising a top plate, a baseplate, and at least four actuators configured to support the top plate over the baseplate and to move the top plate in response to extension or retraction of one or more actuators, wherein at least some of the actuators includes a joint having five degrees of freedom.

[0032] In various embodiments, each of the actuators includes a joint having five degrees of freedom.

[0033] In various embodiments, less than all of the actuators includes a joint having five degrees of freedom.

[0034] In various embodiments, at least one of the actuators includes a joint having four degrees of freedom.

[0035] In various embodiments, top plate includes a first angled side and a second angled side and the baseplate includes a first angled side piece corresponding to and parallel with the first angled side and a second angled side piece corresponding to and parallel with the second angled side.

[0036] In various embodiments, the baseplate includes an intermediate portion from which the side pieces and extend.

[0037] In some embodiments, the intermediate portion is planar.

#### BRIEF DESCRIPTION OF THE DRAWINGS

[0038] The present invention will become more apparent in view of the attached drawings and accompanying detailed description. The embodiments depicted therein are provided by way of example, not by way of limitation, wherein like reference numerals refer to the same or similar elements. The drawings are not necessarily to scale, emphasis instead being placed upon illustrating aspects of the invention. In the drawings:

[0039] FIG. 1 illustrates a variety of conventional kinematic joints;

[0040] FIG. 2 shows a front end view of embodiment of a four-axis stage, or positioner with all actuators retracted, wherein a third actuator (not shown) is behind the first actuator and a fourth actuator (not shown) is behind the second actuator;

[0041] FIG. 3 shows the same front end view of the four-axis stage of FIG. 2, with the first actuator and third actuator extended along an axis ("X AXIS");

[0042] FIG. 4 shows the same end view of the four-axis stage of FIG. 2, with the second actuator and the fourth actuator extended along an axis ("Y AXIS");

[0043] FIG. 5 shows a first (left) side view of the four-axis stage of FIG. 2, with the first and third actuators extended along the "X AXIS", wherein a second actuator (not shown) is behind the first actuator and a fourth actuator (not shown) is behind the third actuator;

[0044] FIG. 6 shows a second (right) side view, opposite the first (left) side view, of the four-axis stage of FIG. 2, with the second and fourth actuators extended along the "Y AXIS", wherein the first actuator (not shown) is behind the second actuator and third actuator (not shown) is behind the fourth actuator;

[0045] FIG. 7 shows the first (left) side view of the four-axis stage of FIGS. 2 and 5, with the first actuator retracted and the third actuator extended to pitch the top plate, wherein the second actuator (not shown) is behind the first actuator and the fourth actuator (not shown) is behind second actuator;

[0046] FIG. 8 shows the second (right) side view of the four-axis stage of FIGS. 2 and 6, with the second actuator extended and the fourth actuator retracted to yaw the top plate, wherein the first actuator (not shown) is behind the second actuator and the third actuator (not shown) is behind fourth actuator;

[0047] FIG. 9 shows a top view of the four-axis stage of FIG. 2, with the base plate omitted for clarity;

[0048] FIG. 10 shows a table of single axis/dual actuator moves that can be applied to a four-axis stage, in accordance with principles of the inventive concepts;

[0049] FIG. 11 shows a table of single axis / single actuator moves that can be applied to a five-axis stage, in accordance with principles of the inventive concepts;

[0050] FIG. 12 shows an embodiment of a five-axis stage top view, in accordance with principles of the inventive concepts;

[0051] FIG. 13 shows another embodiment of multi-axis stage that can achieve a “roll” motion of a top plate, in accordance with principles of the inventive concepts;

[0052] FIGS. 14A-C are views of another embodiment of a four-axis stage using manual actuators capable of single digit micron precision, in accordance with principles of the inventive concepts;

[0053] FIG. 15 is a top view of an embodiment of a five-axis stage employing cylinder magnets in a joint, in accordance with principles of the inventive concepts;

[0054] FIG. 16 is a block diagram of an embodiment of a photonic positioner, including electronic controller, in accordance with principles of inventive concepts;

[0055] FIG. 17A is a top view of an embodiment of a photonic positioner system that employs a four-axis stage, in accordance with principles of inventive concepts; and

[0056] FIG. 17B is a side view of the photonic positioner system of FIG. 17A.

#### DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

[0057] Various aspects of the inventive concepts will be described more fully hereinafter with reference to the accompanying drawings, in which some exemplary embodiments are shown. The present inventive concept may, however, be embodied in many different forms and should not be construed as limited to the exemplary embodiments set forth herein.

[0058] It will be understood that, although the terms first, second, etc. may be used herein to describe various elements, these elements should not be limited by these terms. These terms are used to distinguish one element from another, but not to imply a required sequence of elements. For example, a first element can be termed a second element, and, similarly, a second element can be termed a first element, without departing from the scope of the present invention. As used herein, the term "and/or" includes any and all combinations of one or more of the associated listed items. The term “or” is not used in an exclusive or sense, but in an inclusive or sense.

[0059] It will be understood that when an element is referred to as being “on” or “connected” or “coupled” to another element, it can be directly on or connected or coupled to

the other element or intervening elements can be present. In contrast, when an element is referred to as being “directly on” or “directly connected” or “directly coupled” to another element, there are no intervening elements present. Other words used to describe the relationship between elements should be interpreted in a like fashion (e.g., “between” versus “directly between,” “adjacent” versus “directly adjacent,” etc.).

[0060] The terminology used herein is for the purpose of describing particular embodiments only and is not intended to be limiting of the invention. As used herein, the singular forms “a,” “an” and “the” are intended to include the plural forms as well, unless the context clearly indicates otherwise. It will be further understood that the terms “comprises,” “comprising,” “includes” and/or “including,” when used herein, specify the presence of stated features, steps, operations, elements, and/or components, but do not preclude the presence or addition of one or more other features, steps, operations, elements, components, and/or groups thereof.

[0061] Spatially relative terms, such as “beneath,” “below,” “lower,” “above,” “upper” and the like may be used to describe an element and/or feature's relationship to another element(s) and/or feature(s) as, for example, illustrated in the figures. It will be understood that the spatially relative terms are intended to encompass different orientations of the device in use and/or operation in addition to the orientation depicted in the figures. For example, if the device in the figures is turned over, elements described as “below” and/or “beneath” other elements or features would then be oriented “above” the other elements or features. The device may be otherwise oriented (e.g., rotated 90 degrees or at other orientations) and the spatially relative descriptors used herein interpreted accordingly.

[0062] Exemplary embodiments are described herein with reference to cross-sectional illustrations that are schematic illustrations of idealized exemplary embodiments (and intermediate structures). As such, variations from the shapes of the illustrations as a result, for example, of manufacturing techniques and/or tolerances, are to be expected. Thus, exemplary embodiments should not be construed as limited to the particular shapes of regions illustrated herein but are to include deviations in shapes that result, for example, from manufacturing.

[0063] To the extent that functional features, operations, and/or steps are described herein, or otherwise understood to be included within various embodiments of the inventive concept, such functional features, operations, and/or steps can be embodied in functional blocks, units, modules, operations and/or methods. And to the extent that such functional

blocks, units, modules, operations and/or methods include computer program code, such computer program code can be stored in a computer readable medium, e.g., such as non-transitory memory and media, that is executable by at least one computer processor.

[0064] In example embodiments in accordance with principles of inventive concepts, a parallel position manipulator includes a top plate, a base plate, and four, five, six or more prismatic joint actuators. In preferred embodiments, each actuator includes an actuator joint having five Degrees of Freedom (DOF) at either the base plate or the top plate. In operation, when one or more of the actuators extends or contracts, the pivot points of the remaining actuators are allowed to shift in any axis other than that actuator's axis of motion (that is, an axis defined by the actuator's extension and contraction).

[0065] In example embodiments, magnetic force, gravity, and/or a pliable polymer, such as silicone, may be employed to keep the five DOF pivot points in contact with their respective (that is, top or bottom) plate when the prismatic actuators are retracted.

[0066] In some example embodiments, at least two of the prismatic actuators can be perpendicular to at least two other prismatic actuators.

[0067] In some embodiments, a fifth axis of movement can be added. If a fifth axis is added, its associated prismatic actuator can be arranged perpendicular to the other four prismatic actuators.

[0068] In example embodiments the actuators may be any of several types, such as: piezo actuators, manual micrometer screws, magnetic actuators, stepper motors with linear actuators (either integral or separate), hydraulic cylinders, pneumatic cylinders, or rotary motors with eccentric cams, for example. In example embodiments in accordance with principles of inventive concepts, the parallel position manipulator is configured such that the push and pull forces exerted by each actuator is greater than the shear friction of all the other actuators combined. In example embodiments this is accomplished by employing materials that have a high holding force but a low shear force, for example, such as a hard metal spherical surface magnetically held in contact with a hard flat metal surface. In such embodiments only one of the sides (that is, either the hard metal spherical surface or the hard flat metal surface) is magnetized, because if both sides are magnetic they will be semi-constrained in the sliding axis and, therefore, behave like a spherical 3DOF joint.

[0069] In example embodiments in accordance with principles of inventive concepts, a positioning stage includes a plurality of magnetic prismatic joint actuators, a base plate and a top plate. The top plate may support a device for precise positioning thereof. The top plate

may be supported by a plurality of magnetic prismatic joint actuators, which are, in turn, supported by the base plate. In example embodiments, each actuator is fixed to a portion of the baseplate, which positions each actuator at an angle to the horizontal. In example embodiments, sides of the top plate are formed at the same angle to the horizontal as sides of the baseplate, although other configurations are contemplated within the scope of inventive concepts. Magnets are provided on the angled sides of the top plate. Each actuator includes, at its distal end, a magnetic material, which may be a ferrous metal, for example. In example embodiments, the magnetic material is in the shape of a hemisphere, but other shapes and combinations are contemplated within the scope of inventive concepts. Each magnetic material end is configured to contact a magnet on a side of the top plate to thereby support the top plate above the baseplate.

[0070] In some embodiments, the magnet on the side of the top plate conforms to an outer surface of the top plate. For example, the top plate can have cross section with a planar shape, a V-shape, a semi-cylindrical shape, or another shape.

[0071] In operation, an actuator distal end is maintained in contact with a magnet on an outer surface or side of the top plate through force of the magnet. As an actuator is activated, e.g., extended or retracted, the top plate moves linearly in the direction of motion determined by the motion of the actuator. Therefore, the actuator can be extendible and retractable along an axis. The distal end of an actuator in contact with a magnet on an opposite side of the top plate remains in contact with the magnet, through the magnetic force of the magnet operating upon the magnetic material of the actuator's distal end. At the same time, the distal end of such actuator allows the magnet (and top plate) to slide in a direction dictated by the motion of the activated actuator. With respect to activation, this opposite side actuator can be passive, i.e., not activated, or activated in a different direction, in various embodiments.

[0072] A positioning stage in accordance with principles of inventive concepts can take the form of a parallel position manipulator. Because it is a parallel position manipulator, it does not suffer from the mechanical stack up issues associated with multiple single axis stages stacked on top of each other in what may be referred to as a kinematic chain. Additionally, unlike a hexapod, a positioning stage in accordance with principles of inventive concepts allows for any combination of the four actuators to extend or contract any amount at any speed without the stage binding. Each actuator can be arranged to affect movement in two different axes of the top plate of the stage. To implement a single axis of motion, two

actuators may be moved in a manner in which they complement one another in the desired axis and cancel each other in an undesired axis. As a result, in example embodiments in accordance with principles of inventive concepts, all single-axis stage moves employ dual actuator moves. Single-axis stage moves, and the associated actuator actions, are shown in the tables of FIGS. 10 and 11.

[0073] In addition to being a parallel actuator, a positioning stage in accordance with principles of inventive concepts can have several other benefits. For example, a positioning stage in accordance with principles of inventive concepts is scalable from four to six axes, incrementally, whereas a Stewart Platform always has three or six axes. Unlike a kinematic chain, a positioning stage in accordance with principles of inventive concepts does not exhibit tolerance stack up of individual stages. A positioning stage in accordance with principles of inventive concepts does not require rotary or linear bearings, whereas a kinematic chain requires one for each axis of freedom. With a positioning stage in accordance with principles of inventive concepts, each axis of motion only requires two actuators that move at a fixed, intuitive ratio and, therefore, desired motion is relatively easy to achieve. As previously indicated, this is not the case with a Stewart Platform. Additionally, unlike a Stewart Platform, the speed of actuation need not be controlled to prevent stage binding and individual actuators can be moved without binding the stage. In example embodiments, the positioning stage top plate may be readily removed and replaced simply by decoupling the interfaces, such as a magnetic interfaces.

[0074] In example embodiments the resolution and stiffness of the stage may be determined by the quality of the actuators, the smoothness of the spherical slider components, and the strength of the magnetic (or other) force holding the spherical slider joints together. All of these aspects can be optimized to create a submicron precision stage for a small fraction of the cost of a similar precision hexapod. In many cases, a positioning stage in accordance with principles of inventive concepts will outperform a standard kinematic chain while, at the same time, being more cost-effective. In example embodiments, the holding force (for example, magnetic holding force) of an actuator spherical slider (or other five DOF connection) is greater than the coefficient of friction of all of the other actuator joints. When this is true, the top plate will settle at an equilibrium that allows the four (or more) connections to slide or pivot as needed to ensure that all of the points of contact are maintained.

[0075] A four axis stage with a constrained Z axis in which other degrees of freedom are not interfered with may be implemented in accordance with principles of inventive concepts by using a rigid beam to constrain or restrict movement such Z axis movement, or by replacing one of the four five-DOF actuator joints with a four-DOF joint, restricting motion in the Z axis, as illustrated in FIG. 15.

[0076] FIGS. 2-9, in combination, provide views of example embodiments of a four axis positioning stage in accordance with principles of inventive concepts.

[0077] FIG. 2 shows a front end view of embodiment of a four-axis stage, or positioner with all actuators retracted, wherein a third actuator (not shown) is behind the first actuator and a fourth actuator (not shown) is behind the second actuator. FIGS. 5-9 shows the third and fourth actuators. As can be seen, for example, from FIG. 9, third actuator is behind first actuator and fourth actuator is behind second actuator.

[0078] With respect to FIG. 2, all actuators are retracted in this view. In this example embodiment, the positioning stage is a four-axis stage 100 that includes base plate 102, top plate 104, and a plurality of actuators, which can be prismatic actuators. The plurality of actuators includes a first actuator 106 (i.e., prismatic actuator 1), a second actuator 108 (i.e., prismatic actuator 2), a third actuator 110 (i.e., prismatic actuator 3), and a fourth actuator 112 (i.e., prismatic actuator 4).

[0079] In example embodiments, baseplate 102 includes angled side pieces 118, 120 that are formed at an angle  $\theta$  with respect to the horizontal, where  $\theta = \theta_1 = \theta_2$  in this embodiment. In other embodiments, it may be possible for  $\theta_1 \neq \theta_2$ . Sides 122, 124 of top plate 104 are formed at the same angle  $\theta$  to the horizontal. Therefore, side piece 118 of the base plate 102 is parallel to side 122 of the top plate 104 and side piece 120 of the base plate is parallel to side 124 of the top plate 104. In the embodiment of FIG. 2, the base plate 102 includes an intermediate portion from which the side pieces 118 and 120 extend. The intermediate portion can be a planar piece that lies in the horizontal plane, but the intermediate portion need not be planar in all embodiments.

[0080] In this embodiment, each of the actuators 106, 108, 110, and 112 extends from one of the side pieces 118, 120 of the base plate 102, in a direction toward the top plate 104. For example, in this embodiment, each actuator is secured or coupled to a side piece of the base plate 102 and extends at an angle of 90 degrees with respect to the corresponding side piece 118 or 120 toward the corresponding side 122 or 124 of the top plate 104.

[0081] A distal end of each actuator 106, 108, 110, and 112 includes a magnetic material. In this embodiment, each of the actuators 106, 108, 110, and 112 includes ferrous metal hemispheric ends 134, 136, 138 and 140. Magnets 126, 128, 130, and 132 are disposed on or in the sides 122, 124 of the top plate 104 in locations corresponding to the ferrous metal hemispheric ends 134, 136, 138, and 140 of respective actuators 106, 108, 110, and 112.

[0082] FIG. 3 shows the same front end view of the four-axis stage of FIG. 2, with the first actuator and third actuator extended along an axis ("X AXIS"). In FIG. 3 the first actuator 106 and the third actuator 110 are extended to move the top plate 104 in the direction of the X axis, as indicated by the X-AXIS arrow. As previously indicated, third actuator 110 (actuator 3) is behind first actuator 106 (actuator 1) and the fourth actuator 112 (actuator 4) is behind the second actuator 108 (actuator 2). In example embodiments, actuator 1 106 and actuator 3 110 are extended the same amount in order to provide purely X axis movement. Broken lines indicate the original location of the top plate 104 and magnets 126, 128, which is the position of the top plate in FIG. 2.

[0083] FIG. 4 shows the same end view of the four-axis stage of FIG. 2, with the second actuator and the fourth actuator extended along an axis ("Y AXIS"). In the example embodiment of FIG. 4, actuators 1 106 and 3 110 (X axis) and actuators 2 108 and 4 112 (Y axis) are extended. As previously indicated, third actuator 110 is behind first actuator 106 and fourth actuator 112 is behind second actuator 108. In example embodiments, the first actuator 106 and the third actuator 110 are extended the same amount in order to provide X axis movement and second actuators 108 and fourth actuator 112 are extended the same amount in order to provide Y axis movement. Broken lines indicate the original location of the top plate 104 and magnets 126, 128.

[0084] FIG. 5 shows a first (left) side view of the four-axis stage of FIG. 2, with the first and third actuators extended along the "X AXIS", wherein a second actuator (not shown) is behind the first actuator and a fourth actuator (not shown) is behind the third actuator. In the example embodiment of FIG. 5, the first actuator 106 and the third actuator 110 are extended by the same amount to produce movement solely in the direction of the X axis. Second actuator 108 is behind first actuator 106 and fourth actuator 112 is behind third actuator 110 from this perspective. Broken lines indicate the original location of the top plate 104 and magnets 126, 130.

[0085] FIG. 6 shows a second (right) side view, opposite the first (left) side view, of the four-axis stage of FIG. 2, with the second and fourth actuators extended along the "Y

AXIS", wherein the first actuator (not shown) is behind the second actuator and third actuator (not shown) is behind the fourth actuator. In the embodiment of FIG. 6, the second actuator 108 and the fourth actuator 112 are extended the same amount to produce movement solely in the direction of the Y axis. First actuator 106 is behind second actuator 108 and third actuator 110 is behind fourth actuator 112 from this perspective. Broken lines indicate the original location of the top plate 104 and magnets 128, 132.

[0086] FIG. 7 shows the first (left) side view of the four-axis stage of FIGS. 2 and 5, with the first actuator 106 retracted and the third actuator 110 extended to pitch the top plate 104, wherein the second actuator 108 (not shown) is behind the first actuator and the fourth actuator 112 (not shown) is behind second actuator.

[0087] FIG. 8 shows the second (right) side view of the four-axis stage of FIGS. 2 and 6, with the second actuator 108 extended and the fourth actuator 112 retracted to yaw the top plate 104, wherein the first actuator 106 (not shown) is behind the second actuator and the third actuator 110 (not shown) is behind fourth actuator.

[0088] FIG. 9 shows a top view of the four-axis stage of FIG. 2, with the base plate 102 omitted for clarity. In the example embodiment of FIG. 9, a top view of a four-axis stage in accordance with principles of inventive concepts illustrates the relative position of first, second, third, and fourth actuators 106, 108, 110, and 112, along with respective associated magnets 126, 128, 130, and 132 and top plate 104.

[0089] FIG. 10 shows a table of single axis/dual actuator moves that can be applied to a four-axis stage, in accordance with principles of the inventive concepts. The table of FIG. 10 illustrates combinations of dual actuator moves that implement top plate movements in accordance with principles of inventive concepts. For example, to extend the top plate solely in the positive X axis direction, first actuator 106 and third actuator 110 are extended while second actuator 108 and fourth actuator 112 are left in place; to extend the top plate solely in the positive Y axis direction, second actuator 108 and fourth actuator 112 are extended while first actuator 106 and third actuator 110 are left in place.

[0090] FIG. 11 shows a table of single axis / single actuator moves that can be applied to a five-axis stage, in accordance with principles of the inventive concepts. For example, FIG. 12 shows a fifth actuator 113 added to affect movement of the top plate 4 in a Z AXIS, which lies in a horizontal plane. In other embodiments, a sixth actuator could be provided opposite the fifth actuator.

[0091] The table of FIG. 11 shows single axis, single actuator movements of the fifth actuator 113, as an example, if added to the actuators 106, 108, 110, and 112. That is, the table of FIG. 11 could be appended to the table of FIG. 10 if five actuators were used. Therefore, a five-axis stage, such as that illustrated in FIG. 12, can be provided with movement in the positive Z axis direction effected by extension of fifth actuator 113 and movement in the negative Z axis direction effected by retraction of fifth actuator 113. In example embodiments in which a four axis stage is used, with Z axis constrained, fifth actuator 113 may be replaced with a rigid beam, for example.

[0092] FIG. 13 shows another embodiment of multi-axis stage that can achieve a “roll” motion of a top plate, in accordance with principles of the inventive concepts. In an example embodiment in accordance with principles of inventive concepts, a sixth axis of motion, roll, may be introduced as illustrated in FIG. 13. In this example embodiment top plate 104 is semi-cylindrical, as is magnet 133. In such example embodiments, the operation of the sixth axis does not interfere with operation of the other five. The roll can be achieved through selective extending and/or retracting of actuators 106, 108, 110, and 112. A fifth actuator 113 could again be optional and provided if movement in the Z-axis was intended.

[0093] FIGS. 14A, 14B, and 14C provide end, perspective, and exploded views, respectively, of an example positioner in accordance with principles of inventive concepts. In this example embodiment, top plate 104 and baseplate 102 are V-shaped, with sides having the same angle  $\theta$  with respect to the horizontal, where  $\theta = \theta_1 = \theta_2$  in this embodiment. In other embodiments, it may be possible for  $\theta_1 \neq \theta_2$ . In this example embodiment, first through fourth actuators 106, 108, 110 and 112 penetrate baseplate 102 to contact magnets 135, 137 positioned on sides of top plate 104.

[0094] Magnets 135 and 135 are disposed on or in the sides 122, 124 of the top plate 104 in locations corresponding to the ferrous metal hemispheric ends 134, 136, 138, and 140 at distal ends of respective actuators 106, 108, 110, and 112.

[0095] In example embodiments actuators 106, 108, 110, and 112 may be precision adjustment mechanisms, such as micrometer screws 106a, 108a, 110a, 112a, that allow single-digit micron precision adjustment.

[0096] FIG. 15 is a top view of an embodiment of a five-axis stage employing cylinder magnets in a joint, in accordance with principles of the inventive concepts. As illustrated in the example embodiment of FIG. 15, one of the magnets 139, in this example embodiment, affixed to top plate 104 may be in the form of cylindrical magnets, for example,

that yield a four DOF joint that results in a positioner with restricted motion in the Z axis. The cylinder magnets could be configured, by bending, for example, to yield a sixth axis, of roll.

[0097] FIG. 16 is a block diagram of an embodiment of a photonic positioner, including electronic controller, in accordance with principles of inventive concepts. The block diagram of FIG. 16 depicts a photonic system 200 that employs a photonic device 101, such as a fiber splicer or component thereof, such as an alignment device, in conjunction with a positioner 100 in accordance with principles of inventive concepts. In example embodiments, positioner 100 is controlled by controller 103, which operates the positioner's actuators in a manner previously described to precisely move photonic device 101. Such movement may allow for the alignment of optical fiber ends, for example. Controller 103 may receive feedback, for example, from photonic equipment 101 that the controller employs to adjust positioner 100. In example embodiments in which the photonic equipment 101 is a splicer, for example, sensors indicative of the quality of alignment between fibers may provide indicia to controller 103, which employs such indicia to adjust positioner for precise alignment of optical fibers, for example.

[0098] FIGS. 17A and 17B are top and side views, respectively, of a photonic positioner system 105 that employs positioners in accordance with principles of inventive concepts. In this example embodiment a pair of positioners 100 each support an optical fiber end F1, F2 for splicing. Each positioners 100 may be manipulated, as previously described, for example, using an electronic controller 103 to align the ends of fibers F1, F2 for splicing by an optical fiber slicer including a heating element, such as a plasma heater (not shown), that is configured to heat the fiber ends once aligned using positioners 100. In example embodiments the top plates of positioners 100 may include or support fiber holders 107. Such fiber holders are known and may include grooves in an otherwise flat top surface for holding one or more fibers in place for positioning and splicing.

[0099] While the foregoing has described what are considered to be the best mode and/or other preferred embodiments, it is understood that various modifications can be made therein and that the invention or inventions may be implemented in various forms and embodiments, and that they may be applied in numerous applications, only some of which have been described herein. It is intended by the following claims to claim that which is literally described and all equivalents thereto, including all modifications and variations that fall within the scope of each claim.

[00100] It is appreciated that certain features of the invention, which are, for clarity, described in the context of separate embodiments, may also be provide in combination in a single embodiment. Conversely, various features of the invention which are, for brevity, described in the context of a single embodiment may also be provided separately or in any suitable sub-combination.

[00101] For example, it will be appreciated that all of the features set out in any of the claims (whether independent or dependent) can combined in any given way.

What is claimed is:

1. A parallel positioner, comprising:  
a top plate;  
a baseplate; and  
three or more actuators configured to support the top plate over the baseplate and to move the top plate in response to extension or retraction of one or more actuators, wherein each of the actuators includes a joint having five degrees of freedom.
2. The parallel positioner of claim 1, or any other claim, wherein each of the actuators includes a magnetic joint as a five degree of freedom joint.
3. The parallel positioner of claim 1, or any other claim, wherein the top plate includes angled sides and the actuators are configured to extend from the baseplate to the top plate and to support the top plate along the angled sides of the top plate.
4. The parallel positioner of claim 3, or any other claim, wherein, in a neutral position, the angled sides of the top plate are at the same angle to the horizontal as the angled sides of the baseplate.
5. The parallel positioner of claim 2, or any other claim, wherein each magnetic joint includes an end of an actuator formed of a hemispherical magnetic material and a magnet in a contacting region of a plate.
6. The parallel positioner of claim 5, or any other claim, wherein each magnetic joint is formed on a side of the top plate, each respective actuator end forming the joint is configured to contact a magnet on the side of the top plate and each respective opposing end of the actuator is configured to be fixedly attached to the baseplate.
7. The parallel positioner of claim 1, or any other claim, including four prismatic actuators each forming magnetic joints with sides of the top plate, two actuators per side, and each prismatic actuator fixed to the baseplate at the other end, wherein endpieces of the

baseplate and sides of the top plate, when in a neutral position, are formed at the same angle to the horizontal.

8. The parallel positioner of claim 7, or any other claim, wherein the actuators are configured such that the same amount of extension or retraction of any pair of actuators produces movement of the top plate solely along a single axis, and said extension or retraction is carried out under control of an electronic controller.

9. A method of positioning a device, comprising:  
providing a top plate upon which the device rests;  
providing a baseplate to support the top plate; and  
providing three or more actuators between the top plate and baseplate, the actuators configured to support the top plate over the baseplate and moving the top plate by extension or retraction of one or more actuators, wherein each of the actuators includes a joint having five degrees of freedom.

10. The method of positioning of claim 9, or any other claim, wherein each of the actuators includes a magnetic joint as a five degree of freedom joint.

11. The method of positioning of claim 9, or any other claim, wherein the top plate includes angled sides and the actuators are configured to extend from the baseplate to the top plate and to support the top plate along angled sides of the top plate.

12. The method of positioning of claim 11, or any other claim, wherein, in a neutral position, the angled sides of the top plate are at the same angle to the horizontal as angled sides of the baseplate.

13. The method of positioning of claim 10, or any other claim, wherein each magnetic joint includes an end of an actuator formed of a hemispherical magnetic material and a magnet in a contacting region of a plate.

14. The method of positioning of claim 13, or any other claim, wherein each magnetic joint is formed on a side of the top plate, each respective actuator end of the joint is

configured to contact a magnet on the side of the top plate and each respective opposing end of the actuator is configured to be fixedly attached to the baseplate.

15. The method of positioning of claim 9, or any other claim, including providing four prismatic actuators each forming magnetic joints with sides of the top plate, two actuators per side, and each prismatic actuator fixed to the baseplate at the other end, wherein endpieces of the baseplate and sides of the top plate, when in a neutral position, are formed at the same angle to the horizontal.

16. The method of positioning of claim 15, or any other claim, wherein the actuators are configured such that the same amount of extension or retraction of any pair of actuators produces movement of the top plate solely along a single axis and said extension or retraction is carried out under control of an electronic controller.

17. A photonic positioning device, comprising:

a photonic device;

a top plate supporting the photonic device;

a baseplate; and

three or more actuators configured to support the top plate over the baseplate and to move the top plate in response to extension or retraction of one or more actuators, wherein each of the actuators includes a joint having five degrees of freedom.

18. The photonic positioning device of claim 17, or any other claim, wherein the photonic device is an optical fiber splicer.

19. The photonic positioning device of claim 18, or any other claim, further comprising four prismatic actuators each forming magnetic joints with sides of the top plate, two actuators per side, and each prismatic actuator fixed to the baseplate at the other end, wherein endpieces of the baseplate and sides of the top plate, when in a neutral position, are formed at the same angle to the horizontal.

20. The photonic positioning device of claim 19, or any other claim, wherein the actuators are configured such that the same amount of extension or retraction of any pair of

actuators produces movement of the top plate solely along a single axis, and said extension or retraction is carried out under control of an electronic controller.

21. A parallel positioner, comprising:
  - a top plate,
  - a baseplate, and
  - at least four actuators configured to support the top plate over the baseplate and to move the top plate in response to extension or retraction of one or more actuators, wherein at least some of the actuators includes a joint having five degrees of freedom.
22. The positioner of claim 21, or any other claim, wherein each of the actuators includes a joint having five degrees of freedom.
23. The positioner of claim 21, or any other claim, less than all of the actuators includes a joint having five degrees of freedom.
24. The positioner of claim 21, or any other claim, wherein at least one of the actuators includes a joint having four degrees of freedom.
25. The positioner of claim 21, or any other claim, wherein top plate includes a first angled side and a second angled side and the baseplate includes a first angled side piece corresponding to and parallel with the first angled side and a second angled side piece corresponding to and parallel with the second angled side.
26. The positioner of claim 21, or any other claim, wherein the baseplate includes an intermediate portion from which the side pieces and extend.
27. The positioner of claim 21, or any other claim, wherein the intermediate portion is planar.

## INTERNATIONAL SEARCH REPORT

International application No.

PCT/US17/54272

**Box No. II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)**

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1.  Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:
  
2.  Claims Nos.:  
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
  
3.  Claims Nos.: 2-8, 10-16, 18-20, & 22-27  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

**Box No. III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)**

This International Searching Authority found multiple inventions in this international application, as follows:

1.  As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2.  As all searchable claims could be searched without effort justifying additional fees, this Authority did not invite payment of additional fees.
3.  As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
  
4.  No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

**Remark on Protest**

- The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.
- The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.
- No protest accompanied the payment of additional search fees.
