WO 2005/061540 A3

METHOD FOR THE HUMANIZATION OF ANTIBODIES AND HUMANIZED ANTIBODIES THEREBY OBTAINED

5 BACKGROUND

The present invention relates to a method for the humanization of antibodies, by means of determining and comparing three-dimensional structures, humanized antibodies thereby obtained and their uses in therapy and diagnostics *in vivo*.

10 The therapeutic and diagnostic application of monoclonal antibodies of animal origins in humans has fundamental contraindications especially for therapeutic regimes which necessitate for repeated administrations. In particular, murine monoclonal antibodies have a relatively short half-life and, when used in humans, lack some fundamental functional characteristics of immunoglobulins, such as complement-dependent cytotoxicity and cell-mediated cytotoxicity.

15 Moreover, monoclonal antibodies of non-human origin contain immunogenic amino acid sequences if injected into patients. Numerous studies have shown that after the injection of an exogenous antibody, subjects develop a rather strong immune reaction against the antibody itself (known as HAMA – human anti-mouse antibodies – reaction), completely eliminating its therapeutic usefulness, with the formation of
20 immunocomplexes, alteration of pharmacokinetics, production of allergic reactions, etc. Moreover, considering the growing number of different monoclonal antibodies developed in mice or in other mammals (and thus antigenic for humans) for the therapy of different pathologies, treatments, also for non correlated therapies can be ineffective or even dangerous due to cross-reactivity. Although the production of so-called
25 chimeric antibodies (variable murine regions joined to constant regions of human origin) has yielded some positive result, a significant immunogenicity problem still remains.

Humanized antibodies have at least three potential advantages with respect to antibodies of animal origin in the field of therapeutic use in humans. In the first place, the effector
30 region, being human, can better interact with the other parts of the human immune system, destroying target cells more efficiently by means of complement-dependent cytotoxicity, or cell-mediated, antibody dependent cytotoxicity. Moreover, the human immune system does not recognize the framework or the constant region (C) of the

humanized antibody as exogenous, and hence the antibody response against the humanized antibody is minimized, both relative to that against a murine antibody (totally extraneous) and relative to the response induced by a chimeric antibody (partially extraneous).

5 It has been reported that murine antibodies injected into humans have a much shorter half-life time than normal antibodies (Shaw et al., 1987). Humanized antibodies have a very similar half life to that of natural human antibodies, allowing less frequent administration and lower doses.

10 The basic principle of humanization is configured in transferring the specificity of antigen recognition, i.e. the CDR domains, in the context of a human immunoglobulin ("CDR grafting", Winter and Milstein, 1991). Several examples of humanized antibodies, produced in the attempt to solve the problem of immunogenicity, have been reported (Maeda *et al.*,1991; Singer *et al.*,1993; Tempest *et al.*,1994; Kettleborough *et al.*,1991; Hsiao *et al.*,1994; Baca *et al.*,1997; Leger *et al.*,1997; Ellis *et al.*,1995; Sato *et al.*,1994; Jones *et al.*,1986; Benhar *et al.*,1994; Sha and Xiang,1994; Shearman *et al.*,1991; Rosok *et al.*,1996; Gussow & Seemann,1991; Couto *et al.*,1994; Kashmiri *et al.*,1995; Baker *et al.*,1994; Riechmann *et al.*,1988; Gorman *et al.*,1991; Verhoeyen *et al.*,1988; Foote & Winter,1992; Lewis & Crowe,1991; Co *et al.*,1991; Co *et al.*,1991; Verhoeyen *et al.*,1991; Eigenbrot *et al.*,1994; Hamilton *et al.*,1997; Tempest *et al.*,1995; 20 Verhoeyen *et al.*,1993; Cook *et al.*,1996; Poul *et al.*,1995; Co *et al.*,1992; Graziano *et al.*,1995; Presta *et al.*,1993; Hakimi *et al.*,1993; Roguska *et al.*,1996; Adair *et al.*,1994; Sato *et al.*,1993; Tempest *et al.*,1991; Sato *et al.*,1996; Kolbinger *et al.*,1993; Zhu and Carter,1995; Sims *et al.*,1993; Routledge *et al.*,1991; Roguska *et al.*,1994; Queen *et al.*,1989; Carter *et al.*,1992).

25 The transcription of an antibody from animal (generally murine) to humanized entails the compromise between opposite requirements, whose solution varies case by case. To minimize immunogenicity, immunoglobulin shall maintain as much of the accepting human sequence as possible. In any case, to preserve the original binding properties, the immunoglobulin framework should contain a sufficient number of mutations in the 30 accepting human sequence to guarantee that the conformation of the CDR regions is as similar as possible to that in the donor murine immunoglobulin. As a consequence of these opposite considerations, for many humanized antibodies a significant loss in binding affinity with respect to the corresponding murine antibodies has been reported

(Jones *et al.*, 1986; Shearman *et al.*, 1991; Kettleborough, 1991; Gorman *et al.*, 1991; Riechmann *et al.*, 1988).

Currently, the most common method for the production of humanized immunoglobulin is based on the use of appropriate genomic, synthetic sequences, as well as cDNA
5 (Reichmann *et al.*, 1988).

The patent application EP 592106 discloses a method for the humanization of antibodies from rodents. The method is based on the identification of the amino acid residues exposed at the surface of the three-dimensional structure of the antibody to be humanized, on the identification of the amino acid residues in the same positions on the
10 corresponding human antibody, and on the replacement of the residues identified in the sequence of the rodent antibody with those identified in the human antibody.

DESCRIPTION OF THE INVENTION

The authors of the present invention set up a method to obtain optimized humanized forms of immunoglobulins which are substantially not immunogenic in humans, with an
15 approach that is consistently based on structural data, obtained experimentally, deriving from crystallographic studies. The method of the invention allows to obtain antibodies in a form adapted to therapeutic formulation and to other medical and diagnostic applications.

The invention relates to a method fully based on structural data to conduct the first
20 design stages (generally more subject to error) of humanization. Humanized immunoglobulins have two pairs of heterodimers between light and heavy chain, with at least one of the chains bearing one or more CDRs of animal origin, functionally bound to segments of regions of the framework of human origin. For example, CDRs of animal origin, together with amino acid residues, naturally associated, also of animal
25 origins, are introduced in framework regions of human origin, to produce humanized immunoglobulins able to bind the respective antigens, with affinities comparable to the affinities of the original immunoglobulins of animal origin.

The method of the invention led to obtain humanized antibodies suitable for therapeutic and diagnostic applications. In particular, humanized immunoglobulins have been
30 obtained, derived from anti-TrkA antibodies (Patent EP 1181318) and from anti-NGF antibodies able to bind with high specificity respectively TrkA and NGF, neutralizing the interaction between ligand and receptors. Such molecules are useful for the treatment of tumors which depend on NGF/TrkA, of chronic pain and of inflammatory

forms, and for diagnostic purposes, for in vivo imaging, e.g. on TrkA positive tumors, or on basal forebrain as a precocious marker of Alzheimer's Disease. In particular, humanized anti-TrkA antibodies find specific therapeutic and diagnostic application in the inflammatory forms of the urinary tract and of the pelvic region. In particular, humanized anti-NGF antibodies find specific therapeutic and diagnostic application in pathologies induced by HIV virus, to induce apoptosis of immune cells, such as HIV infected, NGF dependent macrophages.

Therefore, an object of the present invention is to provide a method for the humanization of the VH and VL variable regions of a animal antibody of known sequence, comprising the steps of:

- a) if not available, obtaining the crystallographic structure of the VH and VL regions of the animal antibody;
- b) pre-selecting a series of 0 to n possible frameworks acceptors of human origin or humanized antibodies, whose structure was determined experimentally with a resolution of no less than 3 Å, based on the highest level of homology and identity with the primary sequence of the framework of the animal antibody;
- c) conducting a structural comparison between the VH and VL variable regions of the animal antibody and the regions VH and VL obtained in b), respectively and calculating for each comparison the RMS, to identify the region VH and the region VL of human origin with the smaller RMS;
- d) inserting in appropriate position the sequences of the regions CDR of the animal antibody in the human sequences identified in c);
- e) if necessary, retromutate one or more amino acid residues of the human VH and VL regions identified in c).

Preferably, the modifications of the antibody take place with recombining DNA techniques.

In a preferred embodiment, the animal antibody is an anti-NGF antibody, preferably it is the alpha D11 antibody, and the humanized sequences essentially have the following VH sequences: Hum alpha D11 VH,

EVQLVESGGGLVQPGGSLRLSCAASGFSLTNNNVNWRQAPGKGLEWVGGV
WAGGATDYN SALKSRFTISRDN SKNTAYLQMNSLRAEDTAVYYCARDGGYSS
STLYAMD A WGQGT LVT VSS, (SEQ ID No. 17)

and VL: Hum alpha D11Vk,

DIQMTQSPSSLSASVGDRVTITCRASEDIYNALAWYQQKPGKAPKLLIYNTDTL
HTGVPSRFSGSGSGTDYTLTISSLQPEDFATYFCQHYPRTFGQGTKVEIK
(SEQ ID No. 18).

In an alternative embodiment, the animal antibody is an anti-TrkA antibody, preferably
5 it is the alpha MNAC13 antibody, and the humanized sequences essentially have the
following sequences: VH: HumMNAC13VH,

EVQLLESGLVQPGGSLRLSCAASGFTSTYTMWARQAPGKGLEWVAYISK
GGSTYYPDTVKGRTISRDNKNTLYLQMNSLRAEDSAVYYCARGAMFGND
FFFPMDRWGQGTLVTVSSA, (SEQ ID No. 37)

10 and VL: Hum MNAC13Vk,

DIVLTQSPSSLSASVGDRVTITCSASSSVSYMHWYQQKPGQAPKLLIYTTSNLS
GVPSRFSGSGSGTDYTLTISSLQPEDVATYYCHQWSSYPWTFGGGTKVEIK
(SEQ ID No. 38).

The humanized immunoglobulins of the present invention (or derived fragments which
15 maintain binding activities and other compounds which can be derived) can be produced
by means of known recombining DNA techniques. As a function of the subsequent use
of the humanized immunoglobulins, transgenic animals or transfected cells can be used
for their expression, preferably immortalized eukaryotic cells (such as myeloma or
hybridoma cells), but also prokaryotic hosts, insect or vegetable cells. The coding
20 polynucleotides for the resulting sequences of the humanized immunoglobulins can also
be obtained by synthesis.

The humanized immunoglobulins of the present invention can be used alone or in
combination with other therapeutic agents. In case of use as anti-tumor agents, a
chemotherapeutic agent will be preferred, which may vary depending on the
25 pharmacological application (such as anthracyclin, paclitaxel, cisplatin, gemcytabin,
non steroidal and corticosteroid anti-inflammatory drugs, or immunosuppressants), as
well as with all drugs currently applied in the therapy of each specific pathology.
Humanized immunoglobulins or their complexes can be prepared in the form of
pharmacologically acceptable dosages, which vary depending on the type of
30 administration.

Definitions

The term "substantially identical" within the context of two polynucleotides or
polypeptides (respectively sequences of coding DNA for humanized immunoglobulins

or amino acid sequences of humanized immunoglobulins, or portions thereof) refers to two or more sequences which have a minimum of 80% (preferably 90-95% or more) of identity in the nucleotide or amino acid residues, when compared and aligned with maximum correspondence. Generally, the "substantial identity" is verified in regions that are at least 50 residues long, more preferably on a region of at least 100 residues or, in optimal conditions, on over 150 residues or on the complete sequences. As described below, any two sequences of antibodies can be aligned in only one way, using Kabat's numbering scheme. Consequently, for antibodies the percentage of identity has a unique and well defined meaning. The amino acids of the variable regions of the heavy and light chains of mature immunoglobulins are designated Hx and Lx, with x being the number that designates the position of the amino acid according to Kabat's numbering scheme, Sequences of Proteins of Immunological Interest (National Institutes of Health, Bethesda MD, 1987, 1991). Kabat has determined a list of amino acid sequences of antibodies for each subgroup as well as a list of the most frequent amino acids in each position in each subgroup to generate a consensus sequence. Kabat uses a method to assign a number to each amino acid of each sequence in the list and this method for assigning the number of each residue has become a standard method in the field. Kabat's scheme can be extended to other antibodies not present in his study, aligning the antibody in question with one of the consensus sequences identified by Kabat, basing on the preserved amino acids. Use of Kabat's numbering scheme allows easily to identify the amino acids in equivalent positions in different antibodies. For example, an amino acid in L10 position in an antibody of human origin occupies the equivalent position of an amino acid in L10 position in an antibody of murine origin.

It is well known that the basic structural unit of an antibody comprises a tetramer. Each tetramer is constituted by two identical pairs of polypeptide chains, each of which is composed by a light chain (25 KDa) and by a heavy chain (50-75 KDa). The amino-terminal region of each chain includes a variable region of about 100-110 or more amino acids, which is involved in antigen recognition. The carboxy-terminal region of each chain comprises the constant region that mediates the effector function. The variable regions of each pair of light and heavy chains form the binding site of the antibody. Therefore, an intact antibody has two binding sites.

Light chains are classified as κ or λ . Heavy chains are classified as γ , μ , α , ϵ and they define the isotype of the antibody as respectively IgG, IgM, IgA, IgD e IgE. Inside both

the light and the heavy chain, the variable and constant regions are joined by a “J” region of about 12 amino acids or more, whilst only the heavy chains include a “D” region of about 10 amino acids (Paul, 1993).

5 The variable regions of each pair of light and heavy chains form the binding site of the antibody. They are characterized by the same general structure constituted by relatively preserved regions called frameworks (FR) joined by three hyper-variable regions called complementarity determining regions (CDR) (Kabat *et al.*, 1987; Chothia and Lesk, 1987). The CDRs of the two chains of each pair are aligned by the framework regions, acquiring the function of binding a specific epitope. Starting from the amino-terminal
10 region towards the carboxy-terminal region, the variable domains both of the light chain and of the heavy chain comprise an alternation of FR and CDR regions: FR, CDR, FR, CDR, FR, CDR, FR; consequently, both the heavy chain and the light chain are characterized by three CDRs, respectively CDRH1, CDRH2, CDRH3 and CDRL1, CDRL2, CDRL3. Amino acid assignment to each region was conducted according to
15 the definitions by Kabat (1987 and 1991) and/or Chothia & Lesk (1987), Chothia *et al.* (1989).

Preferably, the analogs of the exemplified humanized immunoglobulins differ from the original immunoglobulins due to conservative amino acid substitutions. In order to classify the amino acid substitutions as conservative or non conservative, amino acids
20 can be grouped as follows:

Group I (hydrophobic lateral chains): M, A, V, L, I;

Group II (neutral hydrophilic lateral chains): C, S, T, N, Q;

Group III (acid lateral chains): D, E;

Group IV (basic lateral chains): K, R;

25 Group V (residues that influence the orientation of the main chain): G, P;

Group VI (aromatic lateral chains): F, Y, W.

Conservative amino acid substitutions regard substitutions between amino acid of the same class, whilst non conservative amino acid substitutions entail an exchange between members of different classes.

30 The term “epitope” includes every protein determinant able to bind an immunoglobulin in specific fashion. Generally, epitopes are formed by sets of chemically active surfaces of macromolecules, such as lateral chains of amino acid or sugars and they generally have specific chemical-physical and conformational characteristics.

The term "immunoglobulins" refers to proteins which consist of one or more polypeptides coded by genes of the immunoglobulins. Immunoglobulins can exist in a variety of forms, in addition to the tetramer antibody form: for example, they include fragments Fv, Fab e F(ab') as well as bifunctional hybrid antibodies (Lanzavecchia *et al.*, 1987) and single chain Fv fragments (Hood *et al.*, 1984; Harlow and Lane, 1988; Hunkapiller and Hood, 1986).

Chimeric antibodies are antibodies whose genes for the light and heavy chains have been engineering starting from gene regions of immunoglobulins belonging to different species. For example, variable segments (V) of the genes of a monoclonal mouse antibody can be joined to constant segments (C) of an antibody of human origin. A therapeutic chimeric antibody, therefore, is a hybrid protein which consists of the domain V which recognizes the antigen deriving from a mouse antibody and in the effector domain C deriving from a human antibody (although other combinations of mammal species can be used).

The term "framework" refers to those portions of the variable regions of the light and heavy chain of the immunoglobulins that are relatively preserved (not belonging to the CDRs) between different immunoglobulins within a species, according to Kabat's definition. Hence, a human framework is a framework region that is substantially identical (at least 85% or more) to the framework that is naturally found in human antibodies.

The term "humanized immunoglobulin" refers to an immunoglobulin which comprises a human framework and at least one CDR deriving from a non human antibody and in which each constant region present is substantially identical to a region of human immunoglobulin (at least 85%, preferably at least 90-95% identical). Hence, all the parts of a humanized immunoglobulin except the CDR are substantially identical to the corresponding regions of one or more sequences of natural human immunoglobulins. For example, the chimeric antibodies, constituted by variable mouse regions and constant regions of human origin, are not included among the humanized immunoglobulins.

DETAILED DESCRIPTION OF THE INVENTION

The method is based on the high resolution structural comparison for the humanization of antibodies of in vivo therapeutic and diagnostic interest. Moreover, humanized immunoglobulins are provided, able to be reactive specifically against the respective

antigens (i.e. NGF neurotrophin and its TrkA receptor). Humanized immunoglobulins have a framework of human origin and they have one or more complementarity determining regions (CDRs) deriving from each original immunoglobulin (i.e. α D11, a rat immunoglobulin, reactive specifically against NGF and MNAC13, a murine immunoglobulin, which specifically recognizes TrkA). Therefore, the immunoglobulins of the present invention, which may be easily produced on a large scale, find therapeutic application not only in the therapy of NGF/TrkA dependent tumor forms, but also in the treatment of chronic pain and inflammatory forms. Moreover, the specific humanized immunoglobulin for the receptor has an additional diagnostic application for in vivo imaging both on TrkA positive tumors and on cells of the basal forebrain (as a precocious marker of Alzheimer's disease).

The present invention uses the recombinant segments of DNA coding the CDR regions of the light and/or heavy chain, able to bind an epitope of interest both on NGF and on TrkA, as in the case of the monoclonal antibodies α D11 and MNAC13 (respectively rat and mouse). The coding DNA segments for these regions are joined to the DNA segments coding appropriate framework regions of human origin. The DNA sequences that code for the polypeptide chains comprising the CDRs of the light and heavy chain of the monoclonal antibodies MNAC13 and α D11 are included in Figure 7A, 7B and 8A, 8B respectively. Because of the degeneration of the genetic code and of the substitutions of non critical amino acids, the DNA sequences can easily be modified.

Moreover, DNA segments typically include an additional control sequence for the expression, operatively bound to the coding sequences for humanized immunoglobulins and comprising regions of heterologous or naturally associated promoters. Preferably, the expression control sequences are systems with eukaryotic promoters in vectors able to transform or transfect eukaryotic host cells, but prokaryotic control sequences can be used as well. Once the vector is incorporated in the appropriate host, the host is maintained in suitable conditions to assure a high level of expression. A further purification follows of the light and heavy chains individually in the form of dimers, of intact antibodies or of other forms of immunoglobulins.

The sequences of coding DNA for the human constant region can be isolated by means of well known procedures from a variety of human cells, but preferably starting from immortalized B cells. The CDRs in the immunoglobulins of the present invention are similarly derived from the monoclonal antibodies α D11 and MNAC13 able to bind

respectively NGF and TrkA and products respectively in rat and mouse. Host cells suitable for the expression and the secretion immunoglobulins can be obtained from many sources such as the American Type Culture Collection (Catalogue of Cell Lines and Hybridomas, Fifth edition (1985) Rockville, Maryland, USA). Preferably, the CDRs incorporated in humanized antibodies have sequences corresponding to those of the CDRs of α D11 and MNAC13 and can include degenerated nucleotide sequences coding the corresponding amino acid sequences of the antibodies themselves.

Generally, the humanization design procedure is cyclical and iterative and it comprises:

The analysis of the amino acid sequence of the murine antibody;

The modeling of the corresponding Fv region;

The analysis and selection of the amino acid sequence of the acceptor framework of the human antibody;

The identification of putative retro-mutations in the selected framework;

The design and the actual construction of the humanized antibody;

The verification, by means of in vitro and/or in vivo assays, of the maintained affinity and specificity of the binding.

If these activities are negatively influenced by the human framework, it will be necessary to change the selection of the framework of the acceptor human antibodies, or to introduce compensating mutations.

Even if the choice of the human framework is configured as the most critical phase of the cycle, no general rules have been established to date. This depends on the fact that the advantages of the various choices (in terms of immunogenicity in the patient) have not been accurately studied from the clinical viewpoint. Therefore, to operate the correct choice of the framework, only a series of approaches are available, which must be combined with the results obtained previously.

In particular, it is possible to use fixed frameworks (usually NEW for the heavy chain and REI for the light chain, since their structures have been available for a long time).

Another approach provides for the use of the frameworks found to be the most homologous in terms of sequence with the antibody to be humanized. There are many databases to search for homologous human antibodies: the choice generally takes into account the length of the CDRs, the identity at the level of canonical residues and of the residues at the interface level, in addition to a higher percentage of identity between the

sequences of the donor and of the acceptor. For a comparison between these two methods, see Graziano *et al.* (1995).

Moreover, according to a variant of the second approach the light chain and the heavy chain can be chosen from two different human antibodies characterized by a higher sequence homology. This approach was proposed by Riechmann *et al.* (1988) and by Shearman *et al.* (1991). In this regard, in general, light and heavy chains deriving from the same antibody have a higher probability of associating correctly, forming a functional binding site, with respect to light and heavy chains deriving from different antibodies, although the fact that the interface between the two chains is quite preserved can equally assure a correct interaction. For a comparison between these two methods, see Roguska *et al.* (1996 and 1996)

Limiting the approach to a framework deriving from a particular human antibody can entail the risk of incurring in somatic mutations which produce immunogenic epitopes even if the frameworks are of human origin. An alternative approach is to use frameworks based on human consensus sequences, where idiosyncratic somatic mutations have been eliminated. The two approaches have been compared: in one case, no difference in binding avidity was noted (Kolbinger *et al.*, 1993), in another one instead the binding proved superior in the case of individual frameworks (Sato *et al.*, 1994).

In any case, the consensus sequences themselves are artificial and therefore, even if they have no idiosyncratic residues, they can create non natural motives which are immunogenic. The alternative (Rosok *et al.*, 1996) is to use germline human sequences collected in the V-BASE database.

The non natural juxtaposition of the murine CDR regions with the variable regions of the framework of human origin can give rise to conformational limits not represented in nature which, unless they are corrected by the substitution of particular amino acid residues, determine the loss of binding affinity. The selection of the amino acid residues to be substituted is partially determined by means of computer modeling. Hardware and software are available to produce three-dimensional images of immunoglobulin molecules. In general, molecular models are produced starting from already resolved crystallographic structures of immunoglobulin domains or chains. The chains to be modeled are compared based on the amino acid resemblance with chains or domains of resolved three-dimensional structures and the chains or the domains, which show the

highest resemblance in terms of sequence, are selected as starting points in the construction of the molecular model. However, the prediction of the antibody structure is not always accurate. In particular, the third CDR region is difficult to model and it always represents a point of uncertainty in the structural prediction of an antibody

5 (Chothia *et al.*, 1987). For this reason, as a rule humanized antibodies, as a first approximation, have far less binding affinity and/or specificity towards the antigen than the starting monoclonal antibody. This requires many successive cycles of point mutations in the attempt to reconstitute the properties of the starting antibody, with a trial and error procedure that cannot be completely rationalized.

10 Considering the growing number of high resolution X-ray structures both of available human and humanized antibodies, the intent was to avoid the uncertainties and ambiguities deriving from use of computer modeling, obtaining high resolution structural data for the Fab fragments of both the antibodies of the invention by means of X-ray crystallography. For this purpose, both antibodies were purified from hybridoma,

15 treated proteolytically with papaine (a protease that cuts at the level of the junction between CH1 and CH2 domain of the heavy chain) which gives origin to the Fab fragments. As a result of the additional purification, both Fab fragments were crystallized and from two databases (low and high resolution), it was possible to solve the structures with the Molecular Substitution method and subsequently to refine them.

20 The approach proposed by the invention, based on structural data obtained experimentally, provides a much more solid and rational starting point, both in the critical phase of the selection of the framework of the acceptor human antibody, and for the identification of putative retro-mutations in the framework selected within the humanization process of both neutralizing antibodies.

25 Amongst the various reported criteria which can guide the selection of the human antibody framework, the one used was the degree of identity between the antibody of murine and human origin at the primary sequence, to extend and complete its results with an analysis based on structural alignment. A compared analysis of the corresponding structures associated to the original criterion assures a much more

30 accurate comparison and consequently a greater probability that the resulting humanized antibody can preserve the characteristics of affinity and specificity of the original murine antibody. Consequently, the strategy employed combines the information deriving from the analysis and comparison of amino acid sequences, both in terms of

degree of identity and of level of homology, with the comparison of the respective three-dimensional structures.

In particular, the information deriving from the optimal alignment of the primary structures has a dual role. In the first place, this analysis allows to reduce the number of possible tertiary structures to be compared, limiting itself to those characterized by a high degree of homology and identity. Among these sequences characterized by an optimal alignment at the primary structure level and for which structural data are available, a further selection was conducted, concentrating only on the resolved structures with high resolution or otherwise with resolution comparable to that of the structures obtained by us (i.e. no greater than 2.5Å). This approach assures a much more accurate alignment of the tertiary structures and a much more significant estimates of the structural differences, expressed in RMS (root mean square deviation: square root of the mean square deviation; Carugo and Pongor, 2001 and 2003). Low resolution data provide rather indicative, and definitely less precise information on the actual relative position of each individual atom in space.

To assess the degree of superposition of each individual structure, of human origin or engineered, the RMS was calculated between atoms of alpha carbon constituting the respective amino acid skeletons, not considering atom pairs with an RMS exceeding 2Å. From this analysis, an information is obtained which must therefore take into account not only the diversity between the structures (expressed by the value of RMS), but also the percentage of atoms of alpha carbon actually employed in calculating each RMS.

These tertiary structure level resemblance data were associated to the comparative analysis of the primary sequences both in terms of identity and of homology.

It is hence deduced that the selection of the optimal framework for humanization is configured as a three-variable problem, which can thus be represented in space, both when associating the homology level and the degree of identity to the structural alignment. This type of analysis was then conducted also reducing the regions in question in the two types of alignment to the regions of the respective frameworks.

Comparing the distributions of the antibodies considered in the space of the three analyzed variables (respectively, value of RMS, percentages of atoms on which RMS was calculated and a similitude index between primary structures, i.e. percentage of overall identity, of overall homology, of identity at the framework level, of homology at

the framework level) with the optimal position in the space of the three variables that each antibody would occupy if it were of human origin, it is possibly clearly to identify the human origin antibody that most approaches this ideal position at the level of primary and tertiary structure. To rationalize this result, in each of the four analyses the
5 deviations from the hypothetical optimal position are calculated for each position of the humanized or human origin antibodies considered.

On the basis of this method of selection, it is possible to choose the acceptor framework in the subsequent process of CDR grafting for the humanization of a given antibody.

In general, it is necessary to minimize the substitutions of amino acid residues of human
10 origin with residues of murine origin, for the introduction of murine residues increases the risk that the antibody will induce a HAMA response in the human patient. On the other hand, the complementarity determining regions (CDRs) contain the residues with the greater probability of interacting with the antigen and for this reason they must be maintained in the humanized antibody. They are defined by means of the sequence
15 according to Kabat or by means of the structure according to Chothia. The advantage of using the second system to define them is that in general the CDRs are shorter and hence the humanized antibody is constituted by a lesser fraction of xenogenic fragments. In any case it has been demonstrated that generally following Kabat's definitions it is possible drastically to reduce the number of cycles required for
20 humanization. Once the CDRs are defined, it is necessary to identify the canonical classes (defined by Chothia and Lesk) to which they belong and subsequently maintain the canonical residues in the humanized antibodies.

It is also essential to analyze the residues that mediate the interaction between the light chain and the heavy chain of the variable domains (Table 1), maintaining any unusual
25 residues in the humanized antibody (Singer *et al.*, 1993; Daugherty *et al.*;1991; De Martino *et al.*, 1991).

Moreover, further amino acids to be maintained are selected based on their possible influence on the conformation of the CDRs and/or on the interaction with the antigen. When the amino acid differs between the framework of animal origin and the equivalent
30 acceptor framework of human original, the amino acid of the acceptor framework should be substituted by the equivalent murine residue, if it is reasonable to expect that the amino acid is in direct non covalent contact with the antigen, or is adjacent to a

CDR region, or in any case interacts with a CDR region (it is situated within 4-6 Å from a CDR region).

TABLE 1

Residues that mediate the interaction between the light chain and the heavy chain of the variable domains

In particular, a further analysis involves other residues which define the so-called Vernier zone, a zone that stabilizes the structure of the CDRs; it is important to maintain the characteristics of this region.

Other residues candidate for mutation are amino acids of the acceptor framework which are unusual for a human immunoglobulin in that position. These residues can be substituted with amino acids deriving from the equivalent position of more typical human immunoglobulins or alternatively residues originating from the equivalent position of the donor framework can be introduced into the acceptor framework when said amino acids are typical for the human immunoglobulins in those particular positions.

Moreover, again on the basis of the consensus sequences of human immunoglobulins, mutations are introduced in the humanized form which insert residues preserved in the human instead of the unusual residues present both in the donor and in the acceptor framework.

5 The respective pairs of crystallographic structures are then modified, first effecting the grafting of the CDRs of animal origin in the human frameworks. Then, all the mutations and retro-mutations described above are introduced. The modified structures are then assembled in composite immunoglobulins. The resulting models are refined by minimizing mechanical energy (in terms of torsion angles and binding angles and
10 distances) using the force field.

For all other regions, different from the specific amino acid substitutions discussed above, the framework regions of the humanized immunoglobulins are usually substantially identical to the framework regions of the human antibodies from which they were derived. In any case in these engineered proteins obtained by grafting, the
15 framework regions can vary relative to the native sequence at the primary structure level due to many amino acid substitutions, deletions or insertions, terminal or intermediate, and other changes. Naturally, most of the residues in the framework region brings a very small or even non-existent contribution to the specificity or affinity of an antibody. Therefore, many individual conservative substitutions in the residues of the framework
20 can be tolerated without appreciable variations of the specificity or affinity in the resulting humanized immunoglobulin. In general, nevertheless, such substitutions are not desirable. It is possible to obtain modifications in the nucleotide sequence with a variety of widely employed techniques, such as site-specific mutagenesis (Gillman & Smith, 1979; Roberts *et al.*, 1987).

25 Alternative, polypeptide fragments can be produced, comprising only a part of the primary structure of the antibody, which fragments retain one or more peculiar activities of the immunoglobulins (e.g., the binding activity). These polypeptide fragments can be produced by means of proteolytic digestion starting from intact antibodies or inserting stop codons in the desired positions in the carriers bearing the coding DNA sequences
30 for the variable regions of the heavy and light chain by means of site specific mutagenesis (in particular after the CH1 region to produce Fab fragments or after the hinge region to produce (Fab')₂ fragments. Antibodies in the form of scFv can be obtained by joining the variable regions of the heavy chain and of the light chain by

means of a linker (Huston *et al.*, 1988; Bird *et al.*, 1988). The Fv or Fab fragments can be expressed in *E. coli* (Buchner and Rudolph, 1991; Skerra *et al.*, 1991) or also in eukaryotic cells, preferably mammal derived. Considering that like many other genes, the genes of the immunoglobulin super family contain distinct functional regions, each characterized by one or more specific biological activities, the genes can be fused to functional regions deriving from other genes (e.g. enzymes) to produce fusion proteins (e.g. immunotoxins) provided with new properties.

The expression of humanized immunoglobulin sequences in bacteria can be used to select humanized immunoglobulin sequences, characterized by higher affinity mutagenizing the CDR regions and producing phage libraries for phage display. Using these libraries, it is possible to perform a screening in the search for variants at the level of the CDRs of the humanized immunoglobulins that have a higher affinity and/or binding specificity for the antigens. Methods to obtain phage-display libraries bearing sequences of the variable regions of immunoglobulins have been amply reported (Cesareni, 1992; Swimmer *et al.*, 1992; Gram *et al.*, 1992; Clackson *et al.*, 1991; Scott & Smith, 1990; Garrard *et al.*, 1991). The sequences resulting from the variants of humanized immunoglobulins, whose CDRs were thus remodeled, are subsequently expressed in a host that is suitable to assure a high expression thereof.

As stated above, the DNA sequences are expressed in the host cells after being operatively bound (i.e. positioned in such a way as to assure their functionality) to expression control sequences. These carriers can typically be replicated in the host organism as episomes or as an integral part of the chromosome DNA. Commonly, the expression carriers contain a selectable marker to allow to identify the cells that have been transformed with the DNA sequences of interest.

For the production of the humanized immunoglobulins of the invention in recombinant form of scFv or in Fab form, prokaryotic systems are preferred. *E. coli* is one of the prokaryotic hosts that is particularly useful for cloning the DNA sequences of the present invention. Moreover, a great number of well characterized promoters is available, e.g. lac or trp operon or β -lactamase or λ phage. Typically, these promoters control expression and bear binding site for the ribosome, for the correct start and finish of transcription and translation. It is possible to increase the half-life of the humanized immunoglobulins of the invention produced in prokaryotic systems by conjugation with polyethylene glycol (PEG).

Other single-cell organisms, such as yeasts, can be used for expression. The host of choice is *Saccharomyces*, using suitable carriers provided with expression control, replication termination and origin sequences.

5 Insect cell cultures can also be used to produce the humanized immunoglobulins of the invention, typically using cells of S2 *Drosophila* transfected in stable fashion or cells of *Spodoptera frugiperda* with the expression system based on the Baculovirus (Putlitz *et al.*, 1990).

10 Plants and cultures of vegetable cells can be used for the expression of the humanized immunoglobulins of the invention. (Larrick & Fry, 1991; Benvenuto *et al.*, 1991; Durin *et al.*, 1990; Hiatt *et al.*, 1989).

However, in all these cases it is impossible to obtain the correct type of glycosylation necessary to assure the effector function in the activation of the human immune system. For this purpose, it is possible to use tissue cultures of mammal cells to express the polypeptides of the present invention in integral form of IgG1, which have proven to be
15 the most effective isotype among seric immunoglobulins in the induction of the immune response (Winnacker, 1987). It should be stressed that, considering that the isotype determines the lytic potential of an antibody, generally the IgG1 isotype is used for therapeutic purposes (since it induces the immune response, both cell-mediated and mediated by the system of the complement), whilst the IgG4 is used for diagnostic
20 applications (Riechmann *et al.*, 1988). In particular, mammal cell are preferred, considering the great number of host cell lines developed for the secretion of intact immunoglobulins, among them the CHO cell lines, several lines of COS, the HeLa cells, myeloma cell lines (NS0, SP/2, YB/0 e P3X63.Ag8.653), transformed B cells or hybridomas. Expression carriers for these cells can include expression control
25 sequences, such as a replication origin, a promoter, an enhancer (Queen *et al.*, 1986), and the sequences required for ribosome binding, RNA splicing and polyadenylation, and sequences for transcription termination. The expression control sequences of choice are promoters deriving from immunoglobulin genes and from viruses, such as SV40, Adenovirus, Bovine Papilloma Virus, Cytomegalovirus and the like. Generally, the
30 expression vector includes a selectable marker, such as the resistance to neomycin.

For the expression of humanized antibodies, it is preferable to cultivate the mammal cell lines with a serum-free medium. For example, the HUDREG-55 cell line can easily be

grown in Serum-Free and Protein-Free Hybridoma Medium Cat. No. S-2897 from Sigma (St. Louis, Mo.).

The genes coding the humanized immunoglobulins of the invention can be used to generate non human transgenic animals, which express the humanized immunoglobulins of interest, typically in a retrievable body fluid such as milk or serum. Such transgenes comprise the polynucleotide sequence coding the humanized immunoglobulins operatively bound to a promoter, usually with an enhancer sequence, such as that of the rodent immunoglobulin or the promoter/enhancer of the casein gene (Buhler *et al.*, 1990; Meade *et al.*, 1990). The transgenes can be transferred into the cells or embryos by means of homologous recombination constructs. Among non human animals used: mouse, rat, sheep, bovine and goat (WO91/08216).

Once they are expressed as intact antibodies, their dimers, the individual light and heavy chains, or in other forms the immunoglobulins of the present invention can be purified following standard procedures, such as precipitation with ammonium sulfate, affinity columns, chromatography on column (Scopes, 1982). For pharmaceutical applications, substantially pure immunoglobulins are necessary, with minimum homogeneity between 90 and 95%, but preferably between 98 and 99% or even higher. Once purified, partially or to the desired homogeneity, proteins can be used for therapeutic use (also in extra-body fashion), for diagnostic use (imaging for the diagnostics of tumors or of Alzheimer's Disease) or to develop and perform biochemical assays, immunofluorescent colorings and the like (see, in general, Lefkovits and Pernis, 1979 and 1981).

A pharmaceutical application of the present invention pertains to the use of humanized immunoglobulin MNAC13 in the form of immunotoxin to eliminate TrkA-expressing cells (in the case of pancreas and prostate tumors). The immunotoxins are characterized by two components and are particularly suitable to kill particular cells both *in vitro* and *in vivo*. One component of the cytotoxic agent that is generally lethal for a cell is absorbed or if it interacts with the cell surface. The second component provides the means to address the toxic agent to a specific target cell type, such as the cells that express the epitope of the TrkA receptor. The two components are chemically bound to each other by means of any one of the great variety of chemical procedures available. For example, when the cytotoxic agent is a protein and the second component is an intact immunoglobulin the link can be mediated by cross-binding and heterobifunctional

agents (SPDP, carbodiimide, glutaraldehyde). Alternatively, the two components can be bound genetically (Chaudhary *et al.*, 1989). The production of various immunotoxins is reported by Thorpe *et al.* (1982).

A great number of cytotoxic agents are suitable for application as immunotoxins.

5 Cytotoxic agents can include radionuclides such as iodine 131 or other isotopes of iodine, yttrium 90, rhenium 188 and bismuth 212 or other isotopes that emit alpha particles, a great number of chemotherapeutic drugs such as vindesin, methotrexate, adriamycin and cisplatin; and cytotoxic proteins, such as proteins that inhibit and ribosomes (such as the pokeweed antiviral protein, the *Pseudomonas* exotoxin A and the
10 diphtheric toxin, ricin A and clavin of vegetable origin) or agents active at the cell surface level (such as phospholipase enzymes such as phospholipase C) – eds. Baldwin and Byers, 1985; Olsnes and Phil, 1982. It should be stressed that the cytotoxic region of the immunotoxin can itself be immunogenic and consequently limit the clinical usefulness of the fusion protein in case of chronic or long term therapy.
15 An alternative to avoid the problem of the immunogenicity of the toxin is to express in fusion with the binding domain of the antibody a protein able to interact with the DNA and bind to this fusion protein the expression carrier that contains the toxin expression cassette. The numerous positive charges of protamin, a human protein that binds the DNA, can interact in stable fashion with the negative charges of the DNA, generating a
20 fusion partner for the neutral charge antibody, much more stable and less immunogenic than the toxin itself. After internalization of the antibody-plasmide complex via receptor mediated endocytosis, the expression of the toxin causes the death of the cell. Moreover, selectivity towards the target cell to be eliminated can be further enhanced by inserting inducible or cell-specific promoters into the toxin expression cassette. This
25 approach is aimed at maximizing the selective elimination of tumor cells while minimizing toxicity side effects (Chen *et al.*, 1995).

The component that addresses the immunotoxin to the correct target includes the MNAC13 humanized immunoglobulin of the present invention in the form of intact immunoglobulin or of the binding fragment or as Fab or Fv fragment. Typically, the
30 antibodies in the immunotoxins are of the human isotype IgM or IgG, but other constant regions can be used as well.

The antibodies and the pharmaceutical compositions of this invention are particularly useful for administration, following any effective methodology to address the antibodies

at the level of the tissue involved in the pathology. This includes (but is not limited to): intraperitoneal, intramuscular, intravenous, subcutaneous, intratracheal, oral, enteral, parenteral, intranasal or dermal administration. The antibodies of the present invention can typically be administered for local application by injection (intraperitoneal or intracranial – typically in a cerebral ventricle – or intrapericardiac or intrabursal) of liquid formulations or by ingestion of solid formulations (in the form of pills, tablets, capsules) or of liquid formulations (in the form of emulsions and solutions). Compositions for parenteral administration commonly comprise a solution of immunoglobulin dissolved in a compatible, preferably aqueous solution. The concentration of the antibody in these formulations can vary from less than 0.005% to 15-20% and it is selected mainly according to the volumes of the liquid, its viscosity, etc., and according to the particular administration mode selected.

Alternatively, the antibodies can be prepared for administration in solid form. The antibodies can be combined with different inert or excipient substances, which can include ligands such as microcrystalline cellulose, gelatin or Arabic rubber; recipients such lactose or starch; agents such as alginic acid, Primogel or corn starch; lubricants such as magnesium stearate, colloidal silicon dioxide; sweeteners such as saccharose or saccharin; or flavors, such as mint and methyl salicylate. Other pharmaceutical administration systems include hydrogel, hydroxymethylcellulose, liposomes, microcapsules, microemulsions, microspheres, etc. Local injections directly in the tissues affected by illness such as tumors is a preferential method for the administration of the antibodies of the present invention.

The antibodies of the invention can be frozen or lyophilized and reconstituted immediately before use in a suitable buffer. Considering that lyophilization and reconstitution can determine a variable loss in the activity of the antibody (for conventional immunoglobulins, class IgM antibodies tend to have a greater loss of activities than class IgG antibodies), administration levels must be calibrated to compensate for this fact.

Thanks to their high blocking capacity, the compositions containing the antibodies of the present invention can be administered for prophylactic and/or therapeutic treatments to prevent or reduce the inflammatory component associated to pathological situations or chronic pain, in particular chronic visceral pain (associated to physiological

disorders, such as dysmenorrhea, dyspepsia, gastrointestinal reflux, pancreatitis, visceralgia or irritable intestine syndrome).

In prophylactic applications, compositions containing antibodies of the present invention are administered to patients who do not yet suffer from a particular pathology
5 to enhance their resistance.

The antibodies of the present invention also provide a method for reducing the volume of prostate or pancreas tumors and for preventing further tumor growth or reduce the rate of growth of the tumor. This effect can be mediated by both the humanized antibodies of the present invention because they are extremely effective in the
10 neutralization of the interaction between NGF and TrkA, necessary to sustain tumor growth and progression in autocrine or paracrine fashion. Moreover the humanized form of MNAC13 interacts with a membrane receptor and hence can also be used for the direct elimination of neoplastic cells because they are able to activate the host's immune response (if administered in the form of IgG1) or to convey a cytotoxic agent localizing
15 it at the level of the cancerous mass (if administered in the form of immunotoxin).

Their administration in the tumor site preferably takes place through direct and localized injection into the tissue or near the tumor site. For systemic administration, doses vary from 0.05 mg/kg per day to 500 mg/kg per day, although dosages in the lower region of the range are preferred because they are easier to administer. Dosages can be calibrated
20 for example to guarantee a particular level in the plasma of the antibody (in the range of about 5-30 mg/ml, preferably between 10-15 mg/ml) and maintain this level for a given period of time until the clinical results are achieved. Humanized antibodies should be eliminated much more slowly and require lower dosages to maintain an effective level in the plasma; moreover, considering the high affinity, administration is less frequent
25 and less sizable than with antibodies having lower affinity. The therapeutically effective dosage of each antibody can be determined during the treatment, based on the reduction in the volume of the tumor or on the rate of growth of the tumor or ideally on the total disappearance of the cancerous pathological state. Effective methods for measuring or assessing the stage of pancreatic or prostatic tumors are based on the measurement of
30 the prostate specific antigen (PSA) in blood, on the measurement of the survival time for pancreas tumors, on the measurement of the slowing or inhibition of diffusion for metastases in the case of both tumor.

For direct injection at the level of the tumor site, dosage depends on different factors including the type, stage and volume of the tumor, along with many other variables. Depending on tumor volume, typical therapeutic doses may vary from 0.01 mg/mm and 10 mg/mm injections which can be administered with the necessary frequency. Another
5 method to assess the effectiveness of a particular treatment is to evaluate the inhibition of the TrkA receptor, e.g. by measuring its activity by means of ELISA assay (Angeles *et al.*, 1996).

It is important to stress that, TrkA is configured not only as a therapeutic target but also as a diagnostic target for *in vivo* imaging, e.g. for imaging of TrkA positive tumors (as a
10 positive or negative marker, depending on tumor type and origin) and imaging on cells of the basal forebrain (as a precocious marker of insurgence of Alzheimer's disease). The MNAC13 humanized antibody of the present invention can also find a wide variety of *in vitro* applications (ELISA, IRMA, RIA, immunohistochemistry).

For diagnostic purposes, the antibodies can be both marked and unmarked. Unmarked
15 antibodies can be used in combination with other marked antibodies (secondary antibodies), which are reactive against humanized, or human antibodies (e.g. specific antibodies for the constant regions of human immunoglobulins). Alternatively, antibodies can be marked directly. A wide variety of markings can be used, e.g. radionuclides, fluorophores, colorings, enzymes, enzymatic substrates, enzymatic
20 factors, enzymatic inhibitors, ligands (in particular aptenic), etc. Numerous types of immunologic assays are available in the sector.

In particular, for imaging diagnostic applications, to the antibody is conjugated an agent that is detectable or marked in isotopic manner (using radioisotopes of iodine, indium, technetium) or in paramagnetic manner (paramagnetic atoms or ions, such as transition
25 elements, actinides and rare earths; in particular, manganese II, copper II and cobalt II) as described by Goding (1986) and Paik *et al.* (1982). Imaging procedures entail the intravenous, intraperitoneal or subcutaneous injection (in lymphatic drainage regions to identify lymph node metastases) and they use detectors of radionuclide emissions (such as scintillation β counters) in the case of immunoscintigraphy; if a paramagnetic
30 marking is used instead, an NMR (Nuclear Magnetic Resonance) spectrometer is used.

The invention shall now be described in its non limiting embodiments, with reference to the following figures:

RESULTS

X-RAY STRUCTURES OF THE Fab FRAGMENT OF THE MNAC13 AND α D11 MONOCLONAL ANTIBODIES

Both monoclonal antibodies were obtained and purified according to standard procedures. The MNAC13 IgG1 and α D11 IgG2a immunoglobulins were expressed in the supernatant by means of culture of hybridoma cells and concentrated by precipitation with 29% ammonium sulfate followed by dialysis in PBS. Both immunoglobulins were purified by affinity chromatography using a column of Protein G Sepharose (Pharmacia).

Following dialysis in phosphate buffer 10 mM pH 7, EDTA 20 mM using Spectra-Por 12/14K membranes (Spectrum) at 4° C, each sample was concentrated by means of Centricon^{*} 50KDa ultrafiltration units (Amicon) and incubated with 13mM Cys and treated with immobilized papaine (Pierce) (with an enzyme : substrate ratio of 1:15) for 5 h at 37°C. The procedure for purifying the respective Fab fragments is diversified, although it is always based on ionic exchange chromatography.

In the case of MNAC13, after dialysis against Tris HCl 100mM pH 8.0, it was possible to eliminate the Fc fragments through a DEAE-Sephacel column (Pharmacia) balanced with the same buffer. FabMNAC13 was collected in the excluded volume whilst the Fc fragments and a fraction of undigested IgG1 were eluted with 250mM NaCl. The Fab fragment was separated from undigested IgG1 by gel filtration on a Superdex G75 (Pharmacia) column balanced with Tris HCl 100mM pH 8.0, NaCl 150mM . The homogeneity and purity of the fractions was controlled by electrophoretic separation on 12% polyacrylamide gel followed by coloring with Coomassie (Figure 1A). The

*-trademark

concentration of the purified protein was determined by means of Lowry assay (Bio-Rad). From 1l of hybridoma supernatant, it was possible to obtain up to 3 mg of MNAC13 Fab (with purity exceeding 99%).

In terms of the purification of the Fab fragment of the α D11 antibody, the sample treated with papaine was dialyzed against 10 mM pH 7.8 phosphate buffer: the Fc fragments were eliminated through a DEAE-Sephacel^{*} column (Pharmacia) balanced with this same buffer. The Fab fragment of α D11 was collected in the excluded volume, whilst the Fc fragments and a fraction of undigested IgG2a were eluted with 250mM pH 6.8 phosphate buffer. The Fab fragment was separated from the undigested IgG2a by means of filtration gel on a Superdex^{*} G75 column (Pharmacia) balanced with 10 mM pH 7.8 phosphate buffer, NaCl 150mM. The homogeneity and purity of the fractions was controlled by electrophoretic separation on 12% polyacrylamide gel followed by coloring with Coomassie (Figure 2A). The concentration of the purified protein was determined by means of Lowry assay (Bio-Rad). From 1l of hybridoma supernatant, it was possible to obtain up to 6 mg of α D11 Fab (with purity exceeding 99%).

Both the Fab fragment of the MNAC13 antibody purified in 10mM Tris pH 8.0, 50mM NaCl, and the Fab fragment of the α D11 antibody purified in 10mM Na phosphate pH 7.8 and 50mM NaCl were concentrated to 5-10 mg/ml by means of Centricon 30KDa ultrafiltration unit (Amicon). The crystallization experiments were conducted following the hanging-drop method at 16°C following a factorial combination approach (Jancarik & Kim, 1991) using Crystal Screen I and II (Hampton Research -Laguna Niguel, CA, USA-) and Screening Kit (Jena BioSciences).

Drops of 2 μ l of the concentrated proteic sample were added to an equal volume of the solution containing the precipitant agent and balanced by diffusion with a solution in the reservoir (0.7 ml) in 24 well Linbro plates.

In terms of the Fab fragment of the MNAC13 antibody, the most promising initial result, obtained with equal volumes of protein and precipitant containing 2M ammonium sulfate, 5% v/v isopropanol (Crystal Screen^{*} II, Reactant #5), was optimized until obtaining crystals that grow in about one week, similar to what is shown in Figure 1B.

In terms of the Fab fragment of the α D11 antibody, the most promising initial result, obtained using equal volumes of protein and precipitant containing 20% PEG4000, 0.6M NaCl, 100mM MES pH 6.5 (Kit number 4, solution C2), required a long

*-trademark

optimization process, modifying the composition of the precipitant agent to PEG4000, 0.6M NaCl, 100mM BTP pH 5.5 and the ratios between protein and precipitant solution (1.5 : 1) until obtaining crystals that grow in about one week, similar to what is shown in Figure 2B.

In both cases, an initial set of low resolution data was collected on the XRD1 diffraction line of the ELETTRA synchrotron (Trieste, Italy), and then a second, more complete set of data at higher resolution was collected on the ID14-EH1 diffraction line of the ESRF synchrotron (Grenoble, France). The crystals were frozen under liquid nitrogen flow with the cooling system by Oxford Cryosystems (Oxford, UK), using in the case of the Fab fragment of the MNAC13 antibody a solution containing 2.2 M ammonium sulfate, 6% v/v isopropanol and 20% v/v glycerol as cryoprotector. A representative high resolution diffraction spectrum for each protein is shown in Figures 1B and 2B.

All four sets of X-ray diffraction data were processed, indexed, integrated and subsequently scaled using the *DENZO* and *SCALEPACK* programs (Otwinowski & Minor, 1997) respectively, while the *CCP4* (Collaborative Computational Project, Number 4, 1994) package was used for data reduction. The statistics for the collection and processing of high and low resolution data of the crystals of the Fab fragment of the MNAC13 antibody are set out in the following table:

X-ray source	ELETTRA	ESRF
Wavelength (Å)	1.000	0.934
Detector	mar345	marCCD
Spatial group	P2 ₁ 2 ₁ 2 ₁	P2 ₁ 2 ₁ 2 ₁
Parameters of the unitary cell		
a (Å)	52.78	52.73
b (Å)	67.53	67.55
c (Å)	111.51	111.43
Mosaicity (°)	0.40	0.47
Resolution interval (Å)	12.0 - 2.50	17.0 - 1.80
	(2.59 - 2.50)	(1.83-1.80)
No. measures	98688	414115
No. of reflexes observed with I ≥ 0	56918	227914
No. of unique reflexes with I ≥ 0	14203 (1371)	38392 (1893)
Completeness (%)	99.5 (99.3)	99.5 (99.6)

Redundancy	4.0 (4.0)	5.9 (4.9)
$\langle I/\sigma(I) \rangle$ of the measured data	9.4 (4.7)	8.2 (1.1)
R_{sym} (%)	5.7 (15.2)	6.3 (39.8)

5 Similarly, the following table summarizes the statistics for the collection and processing of high and low resolution data of the crystals of the Fab fragment of the $\square$ D11 antibody:

	X-ray source	ELETTRA	ESRF
	Wavelength (Å)	1.000	0.934
10	Detector	marCCD	marCCD
	Spatial group	P1	C2
	Parameters of the unitary cell		
	a (Å)	42.685	114.801
	b (Å)	50.626	69.354
15	c (Å)	102.697	64.104
	α (°)	81.977	90
	β (°)	89.116	117.02
	γ (°)	85.957	90
	Mosaicity (°)	0.44	0.40
20	Resolution interval (Å)	47.6 - 2.57 (2.8 - 2.7)	17.0 - 1.70 (1.75-1.70)
	No. measures	124456	492594
	No. of reflexes observed with $I \geq 0$	74241	399184
25	No. of unique reflexes with $I \geq 0$	23413 (2162)	47951 (3198)
	Completeness (%)	98.2 (92.4)	97.2 (78.4)
	Redundancy	5.7 (5.2)	6.7 (7.5)
	$\langle I/\sigma(I) \rangle$ of the measured data	29.6 (6.7)	9.5 (2.1)
	R_{sym} (%)	11.0 (33.5)	5.8 (27.8)

30 Where the values in parenthesis refer to the shell with the highest resolution.
Considering the high number of available structures of Fab fragments, the most convenient method to determine the structure of both proteins was Molecular Substitution. In a research in the Protein Data Bank (Berman *et al.*, 2000) for

homologous structures, the selection criteria gave priority to the combination between comparable resolution and highest level of sequence identity. On these bases, respectively, were selected

for MNAC13: 1BM3: the structure of the complex between Fab fragment of the Opg2 Fab immunoglobulin and the peptide recognized by it (Kodandapani *et al.*, 1999),
5 resolved at a resolution 2.0Å and provided with a sequence identity respectively of 70 and 88% for the heavy and light chain.

for αD11: 1CIC: the structure of the complex of idiotype-anti-idiotype Fab fragments FabD1.3-FabE225 (Bentley *et al.*, 1990), resolved at a resolution 2.5Å and provided
10 with a sequence identity respectively of 82 and 82.65% for the heavy and light chain.

The determination of both structures was obtained by the Molecular Substitution method using the *AMoRe* program (Navaza, 1994), with the respective models using separately the constant domains and variable domains considering the extreme variability of the angle formed by the axis of binary pseudosymmetry between the
15 variable and constant regions. The solution obtained in the determination of the structure, of the Fab fragment of MNAC13 following refined with rigid body is shown in the following table:

Peak	α	β	γ	x	y	z	C _f	R _f	C _I	C _p
V	106.5	20.7	143.9	.1004	.0757	.04680				
C	94.5	13.9	173.3	.1684	.3073	.7355	53.7	39.8	54.8	32.4

Similarly, the solution obtained in the determination of the structure of the Fab fragment
20 of αD11 following refinement with rigid body for the spatial group C2 is shown in the following table:

Peak	α	β	γ	x	y	z	C _f	R _f	C _I	C _p
V	151.0	155.4	43.0	.1424	.0005	.449				
C	17.8	63.7	73.2	.3625	.9532	.1991	55.0	38.9	49.7	35.9

Where V= variable domain

C= constant domain

25 α , β , γ = Eurlian angles (°).

x,y,z = Translation (fractionary).

C_f = Correlation of the amplitudes (x100).

R_f = Crystallographic R factor (x100).

C_i = Correlation of the intensities (x100).

C_p = Correlation of the truncated Patterson function (x100).

The subsequent refinement of the two structures was obtained by means of a cyclic procedures, comprising two alternated phase: manual construction of the model using the interactive software for computer graphics "O" (Kleywegt and Jones, 1994); positional refinement and refinement of B isotropic thermal factors using automatic protocols of the CNS suite, Crystallography and NMR System (Brünger *et al.*, 1998). The procedure after some phases of refinement with rigid body, contemplated different refinement cycles. Once the insertion of all mutations and deletion is completed to complete the models, the localization of the water molecules and any ions and ligands was conducted. At the end, maintaining the model as close as possible to the ideal values in terms of stereochemical, the positional weight w_a and the weight of the thermal factor B r -weight were optimized. The statistics and the final parameters that describe the quality of the model obtained for the Fab fragment of the MNAC13 antibody are summarized in the following table:

Number of protein atoms	3244
Number of solvent atoms	351
Number of sulfate ions	4
Number of Tris molecules	1
Number of isopropanol molecules	1
Resolution interval (Å)	39-1.778
Final R factor	19.35%
Final R_{free} factor (calculated on 10% of the data)	23.22%
Rms Deviations	
Binding distances (Å)	0.008
Binding angles (°)	1.456
Dihedral angles (°)	27.29
Improper angles (°)	0.928
Mean Isotrope Thermal Factor (Å ²)	
Complete protein	23.55
Light chain	24.14
Heavy chain	22.99

Ions (sulfate)	55.94
Tris	46.06
Isopropanol	32.60

Similarly, the statistics and the final parameters that describe the quality of the model obtained for the Fab fragment of the α D11 antibody are summarized in the following table:

	Number of protein atoms	3229
10	Number of solvent atoms	403
	Number of chloride ions	1
	Resolution interval (Å)	30-1.70
	Final R factor	19.54%
	Final R _{free} factor (calculated on 10% of the data)	24.22%
15	Rms Deviations	
	Binding distances (Å)	0.0096
	Angoli di legame (°)	1.6571
	Angoli dieDihedral angle (°)	27.40
20	Improper angles (°)	1.048
	Mean Isotrope Thermal Factor (A ²)	
	Complete protein	25.58
	Light chain	24.14
	Heavy chain	22.99
25	Water molecules	38.80
	Ions (chloride)	20.58

Moreover, both models were examined by final geometry analysis with the PROCHECK suite (Laskowski *et al.*, 1993) as shown in the respective tables and in the respective Ramachandran charts (Figures 1D and 2D).

30 USE OF THE X-RAY STRUCTURES OF THE Fab FRAGMENT OF THE MNAC13
and α D11 MONOCLONAL ANTIBODIES IN THE SELECTION OF A
FRAMEWORK OF HUMAN ORIGIN

In the selection of human antibody framework, the approach described above was follows, which combines on the degree of identity between the antibody of murine and human origin at the primary sequence level to the degree of structural similarity of the polypeptide skeletons.

5 In particular, a series of possible acceptor frameworks of human origin or humanized antibodies was selected on the basis of the highest level both of homology and of identity of the primary structures by a search in the BLAST database. This selection was conducted for both blocking antibodies both considering the entire variable regions of the antibodies and narrowing the search to the framework regions.

10 Within each group of selected antibodies, only those for which structural data with high resolution or otherwise with resolution comparable to that of the structures obtained by us (i.e. no greater than 2.5Å) are available were considered, conducting a search in PDB (Protein Data Bank). The respective amino acid skeleton were then superimposed using the "superimpose" software (Diederichs, 1995).

15 Figures 3G and 4G show the result of the alignment between the Fv region (respectively of MNAC13 and α D11) and the tertiary structures of the alpha carbon atom skeletons of the humanized or human origin antibodies, selected on the basis of the optimal alignment of the primary structures with the antibody to be humanized and of the high resolution of the available structural data.

20 To assess the degree of superposition of each individual structure, of human origin or engineered, both with MNAC13 and with α D11 the RMS was calculated between atoms of alpha carbon constituting the respective amino acid skeletons, not considering atom pairs with an RMS exceeding 2Å.

The selection of the optimal framework for humanization is configured as a three-
25 variable problem, which can thus be represented in space, both when associating the homology level and the degree of identity to the structural alignment. This type of analysis was then conducted also reducing the regions in question in the two types of alignment to the regions of the respective frameworks.

As shown in Figures 3 and 4, the distributions of the antibodies considered in the space
30 of the three analyzed variables (respectively, value of RMS, percentages of atoms on which RMS was calculated and a similitude index between primary structures, i.e. percentage of overall identity –A-, of overall homology –C-, of identity at the

framework level –B-, of homology at the framework level –D-) are mutually coherent and consistent for both cases considered.

Moreover, comparing these distributions with the optimal position in the space of the three variables which each antibody would occupy if it were of human origin, it is possible clearly to identify the human origin antibody that most approximates this ideal position at the primary and tertiary structure level. To rationalize, in the case of both antibodies, this result, in each of the four analyses the deviations from the hypothetical optimal position were calculated for each position of the humanized or human origin antibodies considered (Figure 3E and 3F for MNAC13 and Figure 4E and 4F for α D11). In this case, too, the results are consistent and confirm the previous indications.

On the basis of this method of selection, two different humanized antibodies were selected as acceptor framework in the subsequent process of CDR grafting for the humanization of the two antibodies neutralizing the NGF/TrkA interaction. In particular, Figures 3H and 4H show the structural alignment at the level of the Fv region of the two blocking antibodies with the respective selected humanized antibody, i.e. using the PDB, 1JPS codes for α D11 and 1AD0 codes for MNAC13. Figures 3I and 4I compare the same region of the murine antibody with the model of the same antibody following CDR grafting.

Once the CDRs are defined, the canonical classes (defined by Chothia and Lesk) to which they belong were identified and subsequently the canonical residues in the humanized antibody were maintained: for each antibody, they were highlighted with underlined character in Figure 5 and Figure 6.

In regard to the subsequent analysis of the retro-mutations to be introduced, to maintain the residues that mediate the interaction between the light chain and the heavy chain of the variable domains, the following retro-mutations were inserted to maintain the interface between the two domains:

L46 and H35, H37 for MNAC13

L34, L46, L92 and H35 for α D11.

Moreover, to maintain the characteristics of the Vernier zone, the following retro-mutations were made:

L98 for MNAC13

H71 for α D11 (which in any case regard substitutions for amino acid residues represented in human consensus sequences).

Subsequently, following the comparison with the main consensus sequences of human immunoglobulins, the following retro-mutations were made:

L1, L2, L13, L50, L73, L104 and H24, H48, H49, H73, H76, H82B, H87, H90, H93 for MNAC13

5 L56 for α D11

Moreover, again on the basis of the consensus sequences of human immunoglobulins, in the humanized form of MNAC13 the following mutations were introduced which insert residues preserved in the human instead of the unusual residues present both in the donor and in the acceptor framework.

10 L42 (L $\rightarrow$ Q), L83 (I $\rightarrow$ V) and H83 (Q $\rightarrow$ R), H89 (I $\rightarrow$ V).

For the same reason, the following mutation was introduced in the humanized form of α D11. H67 (V $\rightarrow$ F).

The respective pairs of crystallographic structures were modified, first effecting the grafting of the CDRs of animal origin in the humanized frameworks. Then, all the mutations and retro-mutations described above were introduced. The modified structures were then assembled in composite immunoglobulins. The resulting models were refined by minimizing mechanical energy (in terms of torsion angles and binding angles and distances) using the force field.

HUMANIZATION OF THE MNAC13 AND α D11 MONOCLONAL ANTIBODIES

20 After selecting the donor humanized antibody of the framework to achieve the CDR grafting of MNAC13, the respectively variable regions are designed which combine the murine CDRs of MNAC13 with the framework of the humanized antibody modified according to the mutations set out above. A similar procedure was followed for α D11. Substantially, the two humanized variable regions can be obtained by a procedure based on the overlap assembly PCR method, using oligonucleotides of about 80 bases, which alternate the sense and anti-sense filament with consecutive superposed for a length of 20 bases in such a way as to allow the formation of partially dual filament molecules as a result of hybridation (Figures 7B and 8B). After filling discontinuities by means of Vent polymerase, the dual filament is amplified for PCR using as primers two short oligonucleotides bearing the sequences at the 5' of the dual filament itself together with restriction sites suitable for the subsequent directional cloning (respectively ApaLI/BglIII for the cloning of the variable domain of the light chain and BssHII/BstEII for the cloning of the variable domain of the heavy chain), after digestion with

respective restriction enzymes, in the *pVExpress* plasmid for the variable domain of the light chain (Figure 9A) and in the *pVHexpress* plasmid for the variable domain of the heavy chain (Figure 9B). These carriers allow to express in fusion with the cloned sequences the constant domains of human origin respectively C κ and CH1, CH2 and CH3. Using these vectors, it is therefore possible to express both antibodies in the form of IgG1 molecules (Figure 9C and 9D1) in human cell lines like those listed above.

To obtain both humanized antibodies in the form of Fab fragments, it is sufficient to act solely on the carrier in which the heavy chain is cloned. In particular, it is possible to substitute the entire constant part with the sole CH1 domain amplified for PCR using specific primers provided with restriction sites at the extremes for the *SacII-XbaI* directional cloning (as shown in Figure 9D2).

Lastly, to obtain the MNAC13 humanized antibody in the form of immunotoxin, it is possible to express at the carboxy-terminal of the constant domain CH1 the basic protamin protein amplified for PCR using specific primers provided with the restriction site at the extreme for non direction XbaI cloning (as shown in Figure 9D3).

EXPRESSION AND BINDING ASSAY OF THE MNAC AND α D11 HUMANIZED ANTIBODIES

250 thousand COS cells were co-transfected with 1 μ g of coding plasmidic DNA for VH at VK of each humanized antibody (a total of 2 μ g) by means of FuGENE according to recommended protocol (Roche). The constructs were used to obtain the humanized antibodies in the form of IgG1.

In parallel to the co-transfections of the constructs described above, the corresponding chimeric forms were co-transfected for each antibody, i.e.:

the murine VH of MNAC13 cloned in CMV pVH express and the murine Vk of MNAC13 cloned in CMV pVk express;

in regard to α D11 the rat VH is cloned in fusion with the C γ of human origin in pcDNA1 and the rat Vk is cloned in fusion with the C γ of human origin pcDNA1.

After 72 hours from the transfection, the supernatant containing the immunoglobulins expressed by the host cells was collected, and concentrated using Centriprep 50 (Amicon).

The ability to recognize the respective ligands of the two humanized antibodies was verified by means of ELISA assay and compared with respective chimeric forms. The results are shown in Figure 10 and 11.

For immobilization on plastic, 96 well Maxi sorb plates were incubated at 4°C overnight with a solution containing the respective ligands of the two antibodies (the purified recombinant immunoadhesin TrkA Camel and the murine NGF purified from submandibular glands) at a concentration of 10 µg/ml in 0.1M pH 9.6 sodium carbonate buffer.

After one hour of blocking with PBS containing 3% milk (MPBS) at ambient temperature, concentrated supernatants were incubated with serial dilutions (1:2, 1:20; 1:200) and in parallel also with the supernatant of non transfected COS cells (negative control).

After incubation with the primary antibody (which recognizes the constant Cγ region of human origin) and with the secondary antibody (anti-rabbit conjugated with peroxidase), it is possible to detect the binding activity as optical density at 450 nm (OD450) by means of incubation with the TMB substrate (TECNA). The respective monoclonal antibodies at a concentration of 500 ng/ml were included as positive controls.

Figure 10B shows the results of a similar ELISA assay conducted after purification by means of affinity chromatography of the expressed immunoglobulins.

In detail, the supernatants of the transfected cells were collected and, after removing cellular detritus by centrifuging, they were incubated with 100 µl of Protein G Sepharose and after extensive washings with PBS each protein was eluted with 1 mM HCl and the pH was neutralized immediately after elution with 1 M Tris pH 8.8. The respective concentrations were estimated with Lowry assay.

CLAIMS

1. A method for producing a humanized antibody comprising VH and VL variable regions of an animal antibody of known sequence, comprising the steps of:
 - a) experimentally obtaining a crystallographic structure of the VH and VL regions of the animal antibody;
 - b) pre-selecting a series of 1 to n possible framework acceptors of human origin or of humanized antibodies, whose structures were determined experimentally with a resolution of no greater than 2.5 Å, wherein selected framework acceptors have a high level of homology and identity with the primary sequence of the framework of the animal antibody;
 - c) conducting a structural comparison between the VH and VL variable regions of the animal antibody and the VH and VL regions of the framework acceptors of human origin or of humanized antibodies, respectively, by comparing on a three-variable graph:
 - i) the value of the root mean square deviation (RMS, Å), wherein the RMS is calculated between atoms of alpha carbon constituting the respective amino acid skeletons, not considering atom pairs with an RMS exceeding 2 Å,
 - ii) the percentages of alpha carbon atoms on which RMS was calculated, and
 - iii) the percentage identity and/or homology of the overall primary structure and/or of the primary structure of the framework, in order to identify the VH region and the VL region of human origin or of humanized antibody with the smallest distance from the ideal coordinates, RMS=0 Å, 100% alpha carbon atoms and 100% sequence identity/homology;
 - d) grafting in appropriate positions the sequences of the CDR regions of the animal antibody into the VH region and the VL region of human origin or of the humanized antibody identified in c); wherein the modifications of the antibody take place with recombinant DNA techniques.
2. The method of claim 1, further comprising a step e) of retromutating one or more amino acid residues of the human VH and VL regions identified in (c).
3. The method of claim 1 or 2, wherein the animal antibody is an anti-TrkA antibody.

4. Method as claimed in claim 3, wherein the animal anti-TrkA antibody is the MNAC13 antibody, which comprises the VH sequences SEQ. ID NO. 22 and VL sequence SEQ ID NO. 24.
5. Method as claimed in claim 4, wherein the humanized VH and VL variable sequences have the following sequences: VH: HumMNAC13VH (SEQ ID No. 37), and VL: HumMNAC13Vk (SEQ ID No. 38).
6. An anti-TrkA humanized animal antibody obtainable according to the method as claimed in claim 5.
7. The anti-TrkA humanized animal antibody according to claim 6, wherein the humanized VH and VL variable sequences are more than 95% identical to the sequence SEQ ID No. 37 and the sequence SEQ ID No. 38 respectively.
8. The anti-TrkA humanized animal antibody according to claim 6 comprising the VH sequence SEQ ID No. 37 and the VL sequence SEQ ID No. 38.

FIG. 1 (1 of 2)

FIG. 1 (2 of 2)

FIG. 2 (1 of 2)

FIG. 2 (2 of 2)

FIG. 3 (1 of 2)

E. identity with MNAC13

F. homology with MNAC13

FIG. 3 (2 of 2)

Figure 1 consists of two 3D scatter plots, A and B, illustrating the relationship between RMS (Root Mean Square deviation), %IDENTITA' COMPLESSIVA (Overall Identity), and %ATOMI (Percentage of Atoms) for various protein structures. The vertical axis represents %ATOMI, ranging from 40 to 95. The horizontal axis represents RMS, ranging from 0.0 to 1.0. The depth axis represents %IDENTITA' COMPLESSIVA, ranging from 50 to 90.

Plot A: Shows a cluster of points for various protein structures. The structures are labeled: 1FNS, 1CZ8, 1JPS, 1AD0, 1BJ1, 1FVC, 1VGE, 1AQK, 1FGV, 2FB4, 8FAB, 7FAB, and 1JV3. The points are concentrated in the upper right region, indicating high identity and low RMS.

Plot B: Shows a more dispersed distribution of points for the same protein structures. The structures are labeled: 1BJ1, 1CZ8, 1JPS, 1FNS, 1VGE, 1AD0, 1AQK, 1FVC, 1JV3, 2FB4, 8FAB, 7FAB, and 1JV3. The points are more spread out, indicating a wider range of identity and RMS values.

B. homology with $\alpha D11$
