(54) SYSTEM FOR READING OUT BAR CODED LABELS

(71) We, MITSUBISHI DENKI KABUSHIKI KAISHA, of 2-3 Marunouchi 2-chome, Chiyodaku, Tokyo, Japan, a Japanese Company, do hereby declare the invention, 5 for which we pray that a patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement:—

10 This invention relates to a system for reading out bar coded labels employed with point-of-sales (which is abbreviated to P.O.S.) systems and the like.

15 In order to read out the array of bar coded labels affixed to goods to indicate the type, price, etc. thereof, it has been already proposed to place one of goods having bar coded labels affixed thereto on a merchandise pedestal, pick up an associated bar coded label by a television camera through 20 a transparent window provided on the pedestal, and process the resulting video signal thereby to read out a signal expressed by an array of bar codes printed on the 25 picked-up label. Also in order to correctly read out the bar coded labels by the television camera, scanning lines produced in the television camera are required to coincide in direction with an array of bar 30 codes on each label. To this end, a raster formed on the television camera of the scanning lines produced therein has been rotated at a predetermined speed while an associated bar coded label is picked up by 35 the television camera. When it has been determined that a corresponding video signal from the television camera is of a predetermined code configuration by processing the signal, the bar coded label is read 40 out from that video signal on the presumption that the scanning lines have coincided in direction with the array of the bar codes on the label. However the rotation of the raster on the television camera has led to 45 the necessity of making the television camera into a complicated construction. Also where a multiplicity of such television cameras are used in a single store such as

in a supermarket, it has been required to 50 rotate a raster formed on each of the television cameras and process the resulting video signal from each camera. Therefore there has arisen a problem that equipment in its entirety become expensive.

An object of the present invention is to 55 provide a new and improved system for reading out the array of bar codes printed on bar coded labels which allows television cameras of simple construction compared to the above mentioned cameras to be used.

The present invention provides a system 60 for reading out bar coded labels, comprising at least one television camera means for detecting a bar coded label affixed to each of goods and producing a video signal indicating an array of bar codes printed on the bar coded label, a single video signal writing and reading unit arranged to write the video signal from the television camera means therein as a spatial video pattern and to scan the written video pattern while the scanning direction of said pattern is related thereby to read, as an electrical signal, the video pattern out therefrom, and a signal extraction unit for processing the electrical signal read out from the video signal writing and reading unit to extract the array of bar codes on the picked up label.

In a preferred embodiment of the present invention the system for reading out bar coded labels may comprise a plurality of register units, each including a pick up section having a television camera for detecting bar coded labels affixed to goods and producing a video signal thereof, and a register section for effecting receipts and payments of cash; a single writing and reproducing unit operatively coupled to all of the plurality of register units and including a first multiplexer and a video signal writing and reading means, the first multiplexer arranged to switch the video signals from the respective television cameras in a predetermined order to deliver the switched video signals to the video signal writing and reading means, the video signal writing and

reading means including a plain writing portion into which the video signals are entered thereof in the same pattern as the intact video signals picked up by the associated television cameras and from which the written video signals are read out one at a time while the scanning direction of the pattern of video signals is related; a signal extraction unit including video processing means for converting the video signal read out from the video signal writing and reading means a digital signal, data detector means for determining whether or not the digital signal is a regular coded signal, and a second multiplexer for delivering the regular coded signal from the data detector means to the register section disposed in an associated one of the register units, and control means for controlling the switching operation of the first multiplexer, the writing and reading of the video signal writing and reading means and the switching operation of the second multiplexer.

The present invention will become more readily apparent from the following detailed description taken in conjunction with the accompanying drawing in which:

Figure 1 is a plan view of a bar coded label illustrating directions in which a television camera involved scans the label;

Figures 2A and 2B are diagrams illustrating video signals produced by scanning the bar coded label of Figure 1 in the directions shown in Figure 1 by the television camera; and

Figure 3 is a block diagram of a system for reading out bar coded labels constructed in accordance with the principles of the present invention.

Bar coded labels such as shown by the reference numeral 1 in Figure 1 are generally affixed to goods include the array of bar codes 2 printed thereon to extend more or less widthwise of the label indicating the type, price, etc. of an associated goods item. The array of bar codes 2 is usually picked up by a television camera involved (not shown) to be read out. In order to correctly read out the bar coded labels, scanning lines produced in the television camera are required to be properly located with respect to an array of bar codes on each label. That is, the scanning lines are required to coincide in direction with the array of bar codes. For example, if the scanning lines run along the longitudinal line labelled H_1 of the label 1, that is to say, if the scanning lines coincide in direction with the array of bar codes 2 then the television camera can produce a video signal having a correct waveform as shown in Figure 2A. However if the scanning lines run along a line H_2 oblique to the longitudinal line H_1 as shown in Figure 1, then the resulting video signal has a waveform

such as shown in Figure 2B. That is, the signal does not include signal portions representing a leading and a tailing code respectively. Thus the label cannot be correctly read out.

In order to prevent the video signal from a television camera from having a waveform such as shown in Figure 2B, it has been already proposed to rotate a raster formed on the television camera of scanning lines produced therein. This measure has not only made the television camera into a complicated construction but also, with a multiplicity of such television cameras used in a single store, the equipment in its entirety has been expensive.

In order to eliminate the disadvantages of the prior art practice as above described, the present invention provides a system for reading out bar coded labels comprising at least one television camera for picking up bar coded labels, the scanning direction of the camera or cameras remaining unchanged, and a unit for writing and reading a video signal from the television camera or cameras. The writing and reading out unit is operative to read out the written video signal while the scanning direction of the video signal is changing. Then a signal extraction unit processes the read video signal in a predetermined order to sense a signal represented by an array of bar codes on the label.

Figure 3 shows a system for reading out bar coded labels constructed in accordance with the principles of the present invention. The arrangement illustrated comprises a plurality, in this case, n of register units $10a, 10b, \dots, 10n$. Each of the register units $10a, 10b, \dots, 10n$ includes a pick up section 12 and a register section 14 each suffixed with the same reference character as that identifying the mating register unit. For example, the pick up section $12a$ is disposed in the register unit $10a$ and the register section $14b$ is disposed in the register unit $10b$. Each pick up section 12 is provided with a merchandise pedestal 16 on which goods with bar coded labels (not shown) are adapted to be successively placed and with a television camera 18 disposed below the pedestal 16 to pick up bar coded labels affixed to goods placed on the pedestal 16 one at a time. Each register section 14 includes a register (not shown) also performing the calculations, a display device 20 for displaying summations and the like during the accurate account operation, a typewriter 22 for typewriting characters and figures, a drawer 24 for receipt and payments of cash, a keyboard 26 for manually entering their required data into the register, and a control terminal 28 through 130

which electrical signals can externally enter the register.

All the pick up sections 12a, 12b, . . . 12n are connected to a single writing and reproducing unit generally designated by the reference numeral 30. The writing and reproducing unit 30 includes a first multiplexer 32 connected to outputs of all the television cameras 18 to switch video signals therefrom in order to write the video signals one at a time, and a video signal writing and reading device 34 connected to the multiplexer 32. The writing and reading device 34 is formed of a scan converter and includes a plain writing portion divided into a plurality of writing areas located in predetermined positions A, B, C, . . . The video signal from each television camera passes through the first multiplexer 32 to be written in into that writing area located at an allotted one of the predetermined positions and in the same pattern as the intact video signal produced by the associated television camera. The writing and reproducing unit 34 is further operative to read out the written video signals while a raster involved is rotated in scanning direction.

The video signal read out from the writing and reading device 34 is supplied to a data extraction unit generally designated by the reference numeral 36. The data extraction unit device 36 includes a video processing device 38 connected to the writing and reading device 34 to process the video signal therefrom to deliver a signal in the digital form corresponding to an array of bar codes printed on that bar coded label picked up by the associated television camera to a data detector 40. The data detector 40 examines the digital signal from the video processing device 38 to detect if the examined video signal forms a regular coded signal as will be described hereinafter. The regular video signal as detected by the data detector 40 is applied to a second multiplexer 42, which is, in turn, operative to switch the predetermined video signals to separately supply them to the register sections 14a, 14b, . . . 14n allotted therefor.

As shown in Figure 3, a control device generally designated by the reference numerals 44 is connected at the input to separate outputs of all the pick up sections 12a, 12b, . . . 12n and at the outputs to the first and second multiplexers 32 and 42 respectively and the writing and reading device 34. Thus the control device 44 is operative to control time points at which the first multiplexer 32 switches the video signals delivered thereto from the individual television cameras to introduce them into the allotted portions of the writing and reading device 34 and to correspondingly

specify writing and reading positions on the writing and reading device 34. The control device 44 further serves to control the second multiplexer 42 to deliver the coded signals from the data detector 40 to the associated register sections 14a, 14b, . . . 14n respectively.

The arrangement of Figure 3 is operated as follows: Bar coded labels affixed to those goods placed on the merchandise pedestals 16 located in the respective register units 10a, 10b, . . . 10n are successively picked up by the television cameras 18 and the resulting video signals are entered into the first multiplexer 32. In this case, it is to be noted that the raster each television camera has a predetermined fixed direction.

The video signals from the plurality of the pick up sections 12a, 12b, . . . 12n are switched by the first multiplexer 32 so that the video signals from the television cameras are introduced into the allotted writing portions of the video signal writing and reading device 34 under the control of the control device 44.

In order to switch and select the video signals from the television cameras, the n pedestals 14 can be successively scanned by the mating television cameras in a predetermined order. This measure is advantageous in that the resulting construction is simplified and the control is also simple. Alternatively, a sensor switch (not shown) may be provided on each pickup section 10 to sense each of those merchandise pedestals 16 on which goods have been placed. Then sensed signals from the sensor switches are applied to the first multiplexer 32 to give a "write command" to the latter. Then only the video signals from the pickup sections from which the "write commands" originate are switched to be introduced into the appropriate positions on the writing and reading device 34. The latter measure is advantageous in that the processing time becomes short because, with a multiplicity of pickup sections disposed, only those pedestals 16 having goods placed thereon are processed.

The video signals thus passed through the first multiplexer 32 are written in on the writing and reading device 34 at the predetermined positions A, B, C, . . . corresponding to those pickup sections from which the video signals have been issued respectively.

The video signals thus written are read out in non-destructive manner from each of the writing positions while the scanning direction is changed. After the video signal has been read out from an associated one of the writing positions, a content written in that writing position is erased in

readiness for the next succeeding writing and reading.

The writing and reading device 34 may have the writing positions as predetermined by the respective pickup sections. In this measure the writing and reading positions can be simply controlled because the writing positions are preliminarily determined by the respective pick up sections. Alternatively all the pickup sections may possess the entire writing positions in common. Each time "write command" has been given, an associated video signal is written in a vacant writing position. The latter measure is advantageous in that the resulting writing device can be small-sized. This is because the number of the writing areas is smaller than that of the pickup sections.

In this way an array of bar codes on a bar coded label has been scanned for reading out and written in the writing and reading device 34 under the control of the control device 44. In this case, the scanning lines coincide in direction with the array of bar codes thus written as shown at the line H_1 in Figure 1 then a video signal is produced corresponding to the array of bar codes as shown in Figure 2A. The video processing device 38 converts this video signal to logic voltages so that any portion of the signal higher than a predetermined level has a voltage of logic ONE and any portion of the signal lower than this level has a voltage of logic ZERO. Then the data detector 40 examines the configuration of the logic signal to determine if the examined signal is a regular signal having as determined by the data detector 40 is delivered to the register section 14 disposed in an associated one of the register units 10a, 10b, . . . 10n through the second multiplexer 42 under the control of the control device 44.

When the signal from the second multiplexer 42 is received, the register section actuates the register (not shown), the display device 20 and the typewriter 22 disposed therein to display the required data such as a price of an article of commerce indicated by the array of bar codes and perform the addition operation as determined.

From the foregoing it is seen that video signals from bar coded labels picked up by the n pickup sections are successively processed by a single set of the writing and reading unit and the signal extraction unit after which the processed signals are delivered to the associated register sections, respectively thereby to perform their own summation operations.

While the present invention has been illustrated and described in conjunction with a single preferred embodiment thereof it is to be understood that numerous

changes and modifications may be resorted to without departing from the scope of the present invention. For example, the present invention has been described by reference to a single writing and reproducing unit and a single signal extraction unit connected to process video signals from a plurality of fixed television cameras but because the television camera can be constructed more simply and compactly as compared with those having a rotating raster the invention may be used to construct reading systems including a portable pickup section to read out bar coded labels. This is because the present invention simplifies the scanning by the television camera. In the latter case, the present invention is particularly suitable for handling heavy goods because such goods are not required to be intentionally placed on the merchandise pedestals.

WHAT WE CLAIM IS:—

1. A system for reading out bar coded labels, comprising at least one television camera means for detecting a bar coded label affixed to each of goods and producing a video signal indicating an array of bar codes printed on the bar coded label, a single video writing and reading unit arranged to write said video signal from said television camera means therein as a spatial video pattern and to scan said written video pattern while the scanning direction of said pattern is rotated thereby to read, as an electrical signal, said video pattern out therefrom, and a signal extraction unit for processing said electrical signal read out from said video signal writing and reading unit to extract said array of bar codes on said label. 100

2. A system for reading out bar coded labels as claimed in claim 1 wherein said video signal writing and reading unit is formed of a scan converter. 110

3. A system for reading out bar coded labels as claimed in claim 1 wherein said signal extraction unit includes video processing means for converting said video signal read out from said video signal writing and reading means to a digital signal, and data detector means for determining whether or not said digital signal is a regular coded signal. 115

4. A system for reading out bar coded labels, comprising a plurality of register units, each unit including a pickup section having a television camera for detecting bar coded labels affixed to goods and producing a video signal thereof, and a register section for effecting receipts and payments of cash; a single writing and reproducing unit operatively coupled to all of said plurality of register units and including a first multiplexer and a video signal writing and 125

130

reading means, said first multiplexer arranged to switch said video signals from said respective television cameras in a pre-determined order to deliver said switched 5 video signals to said video signal writing and reading means, said video signal writing and reading means including a plain writing portion into which said video signals are entered in the same pattern as the intact video signals detected by the associated television cameras, and from which said written video signals are read out one at a time while the scanning direction of the pattern of video signals is related; a 10 signal extraction unit including video processing means for converting said video signal read out from said video signal writing and reading means to a digital signal, data detector means for determining 15 whether or not said digital signal is a regular coded signal, and a second multiplexer for delivering said regular coded signals from said data detector means to said register section disposed in an associated one 20 of said register units; and control means for controlling the switching operation of said first multiplexer, the writing and reading of said video signal writing and reading means and the switching operation of said 25 second multiplexer.

30 5. A system for reading out bar coded

labels as claimed in claim 4 wherein each of said pickup section includes a merchandise pedestal, and said television camera included in each of said pickup section detects a bar coded label affixed to each of goods placed on said merchandise pedestal. 35

6. A system for reading out bar coded labels as claimed in claim 4 or claim 5 wherein said first multiplexer successively switches said video signals from said television cameras disposed in said plurality of register units to successively deliver said video signals to said video signal writing and reading means. 40

7. A system for reading out bar coded labels as claimed in claim 5 wherein said first multiplexer switches only said video signals from said television cameras disposed in the pickup sections having goods placed on said merchandise pedestals to deliver the switched video signals to said video signal writing and reading means. 45

8. A system for reading out bar coded labels as claimed in any of claims 4 to 7 wherein said video signal writing and reading means is formed of a scan converter. 50
