## PROBES FOR IMAGING HUNTINGTIN PROTEIN

**[001]** This application claims priority to U.S. Provisional Application No. 62/043,590, filed August 29, 2014.

**[002]** The advent of molecular imaging approaches such as positron emission tomography (PET) and single photon emission computed tomography (SPECT) has enabled measurements of molecular and cellular mechanisms throughout the body in preclinical and clinical settings. Such measurements have widespread diagnostic utility and their use for evaluation of treatment responses and to assist drug development is expanding rapidly. The recent introduction of high-resolution molecular imaging technology is considered by many experts as a major breakthrough that will potentially lead to a revolutionary paradigm shift in health care and revolutionize clinical practice.

**[003]** PET involves the administration to a subject of a positron-emitting radionuclide tracer followed by detection of the positron emission (annihilation) events in the body. The radionuclide tracer is typically composed of a targeting molecule having incorporated therein one or more types of positron-emitting radionuclides.

**[004]** Many new molecular probes labeled with positron-emitting radionuclides and associated PET imaging assays are under development to target, detect, visualize, and quantify various extracellular and intracellular molecules and processes associated with diseases such as cancer, heart disease, and neurological disorders. For instance, several types of agents have been synthesized and evaluated for imaging amyloid  $\beta$  ( $A\beta$ ) plaques in patients with Alzheimer's disease (AD) including, arylbenzothiazoles, stilbenes, imidazopyridines, pyridylbenzothiazoles, pyridylbenzoxazoles and pyridylbenzofurans (Swahn *et al.*, *Bioorganic & Medicinal Chemistry Letters*, 20 (2010) 1976-1980). Furthermore, styrylbenzimidazole (SBIM) derivatives have been developed as agents for imaging neurofibrillary tangles (NFT), composed of hyperphosphorylated tau protein, in patients with AD. In binding experiments using recombinant tau and amyloid  $\beta_{1-42}$  ( $A\beta_{1-42}$ ) aggregates, 4-[(*E*)-2-(6-iodo-1*H*-benzimidazol-2-yl)ethenyl]-*N,N*-dimethylaniline (SBIM-3) showed higher affinity for the tau aggregates than  $A\beta_{1-42}$  aggregates (ratio of  $K_d$  values was 2.73). In *in vitro* autoradiography and fluorescent staining, [ $^{125}$ I]SBIM-3 (or SBIM-3) bound NFT in

sections of AD brain tissue. In biodistribution experiments using normal mice, all [<sup>125</sup>I]SBIM derivatives showed high initial uptake into (3.20-4.11%ID/g at 2 min after the injection) and rapid clearance from (0.12-0.33%ID/g at 60 min after the injection) the brain (Matsumura *et al.*, *Bioorganic & Medicinal Chemistry*, 21 (2013) 3356-3362).

**[005]** Huntington's disease (HD) is an inherited progressive neurodegenerative disorder, characterized by motor, cognitive, and psychiatric deficits as well as neurodegeneration and brain atrophy beginning in the striatum and the cortex and extending to other subcortical brain regions. It belongs to a family of neurodegenerative diseases caused by mutations in which an expanded CAG repeat tract results in long stretches of polyglutamine (polyQ) in the encoded protein. This family also includes dentatorubral-pallidoluysian atrophy (DRPLA), spinal and bulbar muscular atrophy (SBMA) and the spinocerebellar ataxias (SCAs). Apart from their polyQ repeats, the proteins involved are unrelated, and although they are all widely expressed in the central nervous system and peripheral tissues, they lead to characteristic patterns of neurodegeneration. In HD, the selective neurodegeneration of the  $\gamma$ -aminobutyric acid-releasing spiny-projection neurons of the striatum is predominant, although loss of neurons in many other brain regions has also been reported. In the unaffected population, the number of CAG repeats in the IT<sub>15</sub> gene that encodes the HD protein huntingtin (HTT protein) varies from 6 to 35; repeats of 36 or more define an HD allele. The length of the CAG expansion is inversely correlated with age of disease onset, with cases of juvenile onset characterized by expansions of more than 60 repeats. HD has a prevalence of 5-10 cases per 100,000 worldwide, which makes it the most common inherited neurodegenerative disorder. HTT protein is a 348-kDa multidomain protein that contains a polymorphic glutamine/proline-rich domain at its amino-terminus. The longer polyQ domain seems to induce conformational changes in the protein, which causes it to form intracellular aggregates that, in most cases, manifest as nuclear inclusions. However, aggregates can also form outside the nucleus. HTT protein is present in the nucleus, cell body, dendrites and nerve terminals of neurons, and is also associated with a number of organelles including the Golgi apparatus, endoplasmic reticulum and mitochondria.

**[006]** Several clinical trials are investigating means to alleviate or reduce symptoms and slow progression in clinically diagnosed HD. Consistent with other medical conditions, treatments might be ideally initiated at or before the earliest signs of

disease. There are at least two primary challenges to the design of clinical trials for pre-HD: selection of participants who are most likely to show measurable change over the course of a clinical trial, and development of outcome measures that are sensitive to interventions and can demonstrate variation over the natural history of pre-HD. In order to meet these and other challenges to preventive clinical trials, indicators of very early disease are required.

**[007]** In view of the central role of the accumulation of aggregated forms of HTT protein in the pathogenesis of HD, there is a need for molecular probes that bind to such abnormalities with high sensitivity and specificity, for molecular imaging in the living subject using PET. The compounds described herein meet this and other needs.

[009] Also provided is a method of generating diagnostic images in an individual comprising administering an effective amount of an imaging agent described herein to an individual, and generating an image of at least a part of said individual.

[010] As used in the present specification, the following words, phrases and symbols are generally intended to have the meanings as set forth below, except to the extent that the context in which they are used indicates otherwise. The following abbreviations and terms have the indicated meanings throughout:

[011] A dash (“—”) that is not between two letters or symbols is used to indicate a point of attachment for a substituent. For example, —CONH<sub>2</sub> is attached through the carbon atom.

[012] As used herein the terms “group”, “radical” or “fragment” refer to a functional group or fragment of a molecule attachable to a bond or other fragments of molecules.

[013] When a range of values is given (e.g., C<sub>1-6</sub> alkyl), each value within the range as well as all intervening ranges are included. For example, “C<sub>1-6</sub> alkyl” includes C<sub>1</sub>, C<sub>2</sub>, C<sub>3</sub>, C<sub>4</sub>, C<sub>5</sub>, C<sub>6</sub>, C<sub>1-6</sub>, C<sub>2-6</sub>, C<sub>3-6</sub>, C<sub>4-6</sub>, C<sub>5-6</sub>, C<sub>1-5</sub>, C<sub>2-5</sub>, C<sub>3-5</sub>, C<sub>4-5</sub>, C<sub>1-4</sub>, C<sub>2-4</sub>, C<sub>3-4</sub>, C<sub>1-3</sub>, C<sub>2-3</sub>, and C<sub>1-2</sub> alkyl.

[014] When a moiety is defined as being optionally substituted, it may be substituted as itself or as part of another moiety. For example, if R<sup>x</sup> is defined as “C<sub>1-6</sub> alkyl or OC<sub>1-6</sub> alkyl, wherein C<sub>1-6</sub> alkyl is optionally substituted with halogen”, then both the C<sub>1-6</sub> alkyl group alone and the C<sub>1-6</sub> alkyl that makes up part of the OC<sub>1-6</sub> alkyl group may be substituted with halogen.

[015] The term “alkyl” encompasses straight chain and branched chain having the indicated number of carbon atoms, usually from 1 to 20 carbon atoms, for example 1 to 8 carbon atoms, such as 1 to 6 carbon atoms. For example C<sub>1-6</sub> alkyl encompasses both straight and branched chain alkyl from 1 to 6 carbon atoms. Examples of alkyl groups include methyl, ethyl, propyl, isopropyl, *n*-butyl, *sec*-butyl, *tert*-butyl, pentyl, 2-pentyl, isopentyl, neopentyl, hexyl, 2-hexyl, 3-hexyl, 3-methylpentyl, and the like. When an alkyl residue having a specific number of carbons is named, all geometric isomers having that number of carbons are intended to be encompassed; thus, for example, “butyl” is meant to include *n*-butyl, *sec*-butyl, isobutyl and *tert*-butyl; “propyl” includes *n*-propyl and isopropyl. “Lower alkyl” refers to alkyl groups having 1 to 6 carbons.

[016] By “alkoxy” is meant an alkyl group of the indicated number of carbon atoms attached through an oxygen bridge such as, for example, methoxy, ethoxy, propoxy,

isopropoxy, *n*-butoxy, *sec*-butoxy, *tert*-butoxy, pentoxy, 2-pentyloxy, isopentoxy, neopentoxy, hexoxy, 2-hexoxy, 3-hexoxy, 3-methylpentoxy, and the like. Alkoxy groups will usually have from 1 to 6 carbon atoms attached through the oxygen bridge. "Lower alkoxy" refers to alkoxy groups having 1 to 6 carbons. By "cycloalkoxy" is meant a cycloalkyl group that is likewise attached through an oxygen bridge.

**[017]** "Alkynyl" refers to an unsaturated branched or straight-chain alkyl group having the indicated number of carbon atoms (e.g., 2 to 8 or 2 to 6 carbon atoms) and at least one carbon-carbon triple bond derived by the removal of two molecules of hydrogen from adjacent carbon atoms of the corresponding alkyl. Alkynyl groups include, but are not limited to, ethynyl, propynyl (e.g., prop-1-yn-1-yl, prop-2-yn-1-yl) and butynyl (e.g., but-1-yn-1-yl, but-1-yn-3-yl, but-3-yn-1-yl). "Lower alkynyl" refers to alkynyl groups having 2 to 6 carbons.

**[018]** "Aryl" indicates an aromatic carbon ring having the indicated number of carbon atoms, for example, 6 to 12 or 6 to 10 carbon atoms. Aryl groups may be monocyclic or polycyclic (e.g., bicyclic, tricyclic). In some instances, both rings of a polycyclic aryl group are aromatic (e.g., naphthyl). In other instances, polycyclic aryl groups may include a non-aromatic ring (e.g., cycloalkyl, cycloalkenyl, heterocycloalkyl, heterocycloalkenyl) fused to an aromatic ring, provided the polycyclic aryl group is bound to the parent structure via an atom in the aromatic ring. Thus, a 1,2,3,4-tetrahydronaphthalen-5-yl group (wherein the moiety is bound to the parent structure via an aromatic carbon atom) is considered an aryl group, while 1,2,3,4-tetrahydronaphthalen-1-yl (wherein the moiety is bound to the parent structure via a non-aromatic carbon atom) is not considered an aryl group. Similarly, a 1,2,3,4-tetrahydroquinolin-8-yl group (wherein the moiety is bound to the parent structure via an aromatic carbon atom) is considered an aryl group, while 1,2,3,4-tetrahydroquinolin-1-yl group (wherein the moiety is bound to the parent structure via a non-aromatic nitrogen atom) is not considered an aryl group. However, the term "aryl" does not encompass or overlap with "heteroaryl" regardless of the point of attachment (e.g., both quinolin-5-yl and quinolin-2-yl are heteroaryl groups). In some instances, aryl is phenyl or naphthyl. In certain instances, aryl is phenyl.

**[019]** Bivalent radicals formed from substituted benzene derivatives and having the free valences at ring atoms are named as substituted phenylene radicals. Bivalent radicals derived from univalent polycyclic hydrocarbon radicals whose names end in

"-yl" by removal of one hydrogen atom from the carbon atom with the free valence are named by adding "-idene" to the name of the corresponding univalent radical, e.g., a naphthyl group with two points of attachment is termed naphthylidene.

**[020]** "Cycloalkyl" indicates a non-aromatic, fully saturated carbocyclic ring having the indicated number of carbon atoms, for example, 3 to 10, or 3 to 8, or 3 to 6 ring carbon atoms. Cycloalkyl groups may be monocyclic or polycyclic (e.g., bicyclic, tricyclic). Examples of cycloalkyl groups include cyclopropyl, cyclobutyl, cyclopentyl, and cyclohexyl, as well as bridged and caged ring groups (e.g., norbornane, bicyclo[2.2.2]octane). In addition, one ring of a polycyclic cycloalkyl group may be aromatic, provided the polycyclic cycloalkyl group is bound to the parent structure via a non-aromatic carbon. For example, a 1,2,3,4-tetrahydronaphthalen-1-yl group (wherein the moiety is bound to the parent structure via a non-aromatic carbon atom) is a cycloalkyl group, while 1,2,3,4-tetrahydronaphthalen-5-yl (wherein the moiety is bound to the parent structure via an aromatic carbon atom) is not considered a cycloalkyl group.

**[021]** "Cycloalkenyl" indicates a non-aromatic carbocyclic ring, containing the indicated number of carbon atoms (e.g., 3 to 10, or 3 to 8, or 3 to 6 ring carbon atoms) and at least one carbon-carbon double bond derived by the removal of one molecule of hydrogen from adjacent carbon atoms of the corresponding cycloalkyl. Cycloalkenyl groups may be monocyclic or polycyclic (e.g., bicyclic, tricyclic). Examples of cycloalkenyl groups include cyclopropenyl, cyclobutenyl, cyclopentenyl, cyclopentadienyl, and cyclohexenyl, as well as bridged and caged ring groups (e.g., bicyclo[2.2.2]octene). In addition, one ring of a polycyclic cycloalkenyl group may be aromatic, provided the polycyclic alkenyl group is bound to the parent structure via a non-aromatic carbon atom. For example, inden-1-yl (wherein the moiety is bound to the parent structure via a non-aromatic carbon atom) is considered a cycloalkenyl group, while inden-4-yl (wherein the moiety is bound to the parent structure via an aromatic carbon atom) is not considered a cycloalkenyl group.

**[022]** The term "halo" includes fluoro, chloro, bromo, and iodo, and the term "halogen" includes fluorine, chlorine, bromine, and iodine.

**[023]** "Haloalkyl" includes straight and branched carbon chains having the indicated number of carbon atoms (e.g., 1 to 6 carbon atoms) substituted with at least one halogen atom. In instances wherein the haloalkyl group contains more than one halogen atom, the halogens may be the same (e.g., dichloromethyl) or different (e.g.,

chlorofluoromethyl). Examples of haloalkyl groups include, but are not limited to, chloromethyl, dichloromethyl, trichloromethyl, fluoromethyl, difluoromethyl, trifluoromethyl, chlorofluoromethyl, 2-fluoroethyl, 2,2-difluoroethyl, 2,2,2-trifluoroethyl, 1,2-difluoroethyl, 2-chloroethyl, 2,2-dichloroethyl, 2,2,2-trichloroethyl, 1,2-dichloroethyl, pentachloroethyl, and pentafluoroethyl.

**[024]** "Heteroaryl" indicates an aromatic ring containing the indicated number of atoms (e.g., 5 to 12, or 5 to 10 membered heteroaryl) made up of one or more heteroatoms (e.g., 1, 2, 3 or 4 heteroatoms) selected from N, O and S and with the remaining ring atoms being carbon. Heteroaryl groups do not contain adjacent S and O atoms. In some embodiments, the total number of S and O atoms in the heteroaryl group is not more than 2. In some embodiments, the total number of S and O atoms in the heteroaryl group is not more than 1. Unless otherwise indicated, heteroaryl groups may be bound to the parent structure by a carbon or nitrogen atom, as valency permits. For example, "pyridyl" includes 2-pyridyl, 3-pyridyl and 4-pyridyl groups, and "pyrrolyl" includes 1-pyrrolyl, 2-pyrrolyl and 3-pyrrolyl groups. When nitrogen is present in a heteroaryl ring, it may, where the nature of the adjacent atoms and groups permits, exist in an oxidized state (i.e.,  $N^+-O^-$ ). Additionally, when sulfur is present in a heteroaryl ring, it may, where the nature of the adjacent atoms and groups permits, exist in an oxidized state (i.e.,  $S^+-O^-$  or  $SO_2$ ). Heteroaryl groups may be monocyclic or polycyclic (e.g., bicyclic, tricyclic).

**[025]** In some instances, a heteroaryl group is monocyclic. Examples include pyrrole, pyrazole, imidazole, triazole (e.g., 1,2,3-triazole, 1,2,4-triazole, 1,3,4-triazole), tetrazole, furan, isoxazole, oxazole, oxadiazole (e.g., 1,2,3-oxadiazole, 1,2,4-oxadiazole, 1,3,4-oxadiazole), thiophene, isothiazole, thiazole, thiadiazole (e.g., 1,2,3-thiadiazole, 1,2,4-thiadiazole, 1,3,4-thiadiazole), pyridine, pyridazine, pyrimidine, pyrazine, triazine (e.g., 1,2,4-triazine, 1,3,5-triazine) and tetrazine.

**[026]** In some instances, both rings of a polycyclic heteroaryl group are aromatic. Examples include indole, isoindole, indazole, benzimidazole, benzotriazole, benzofuran, benzoxazole, benzisoxazole, benzoxadiazole, benzothiophene, benzothiazole, benzoisothiazole, benzothiadiazole, 1*H*-pyrrolo[2,3-*b*]pyridine, 1*H*-pyrazolo[3,4-*b*]pyridine, 3*H*-imidazo[4,5-*b*]pyridine, 3*H*-[1,2,3]triazolo[4,5-*b*]pyridine, 1*H*-pyrrolo[3,2-*b*]pyridine, 1*H*-pyrazolo[4,3-*b*]pyridine, 1*H*-imidazo[4,5-*b*]pyridine, 1*H*-[1,2,3]triazolo[4,5-*b*]pyridine, 1*H*-pyrrolo[2,3-*c*]pyridine, 1*H*-pyrazolo[3,4-*c*]pyridine, 3*H*-imidazo[4,5-*c*]pyridine, 3*H*-[1,2,3]triazolo[4,5-

**[027]** In other instances, polycyclic heteroaryl groups may include a non-aromatic ring (e.g., cycloalkyl, cycloalkenyl, heterocycloalkyl, heterocycloalkenyl) fused to a heteroaryl ring, provided the polycyclic heteroaryl group is bound to the parent structure via an atom in the aromatic ring. For example, a 4,5,6,7-tetrahydrobenzo[*d*]thiazol-2-yl group (wherein the moiety is bound to the parent structure via an aromatic carbon atom) is considered a heteroaryl group, while 4,5,6,7-tetrahydrobenzo[*d*]thiazol-5-yl (wherein the moiety is bound to the parent structure via a non-aromatic carbon atom) is not considered a heteroaryl group.

**[028]** "Heterocycloalkyl" indicates a non-aromatic, fully saturated ring having the indicated number of atoms (e.g., 3 to 10, or 3 to 7, membered heterocycloalkyl) made up of one or more heteroatoms (e.g., 1, 2, 3 or 4 heteroatoms) selected from N, O and S and with the remaining ring atoms being carbon. Heterocycloalkyl groups may be monocyclic or polycyclic (e.g., bicyclic, tricyclic).

**[029]** Examples of monocyclic heterocycloalkyl groups include oxiranyl, aziridinyl, azetidiny, pyrrolidinyl, imidazolidinyl, pyrazolidinyl, piperidinyl, piperazinyl, morpholinyl and thiomorpholinyl.

**[030]** When nitrogen is present in a heterocycloalkyl ring, it may, where the nature of the adjacent atoms and groups permits, exist in an oxidized state (i.e., N<sup>+</sup>-O<sup>-</sup>).

Examples include piperidinyl *N*-oxide and morpholinyl-*N*-oxide. Additionally, when sulfur is present in a heterocycloalkyl ring, it may, where the nature of the adjacent atoms and groups permits, exist in an oxidized state (i.e.,  $S^+-O^-$  or  $-SO_2-$ ). Examples include thiomorpholine *S*-oxide and thiomorpholine *S,S*-dioxide.

**[031]** In addition, one ring of a polycyclic heterocycloalkyl group may be aromatic (e.g., aryl or heteroaryl), provided the polycyclic heterocycloalkyl group is bound to the parent structure via a non-aromatic carbon or nitrogen atom. For example, a 1,2,3,4-tetrahydroquinolin-1-yl group (wherein the moiety is bound to the parent structure via a non-aromatic nitrogen atom) is considered a heterocycloalkyl group, while 1,2,3,4-tetrahydroquinolin-8-yl group (wherein the moiety is bound to the parent structure via an aromatic carbon atom) is not considered a heterocycloalkyl group.

**[032]** "Heterocycloalkenyl" indicates a non-aromatic ring having the indicated number of atoms (e.g., 3 to 10, or 3 to 7, membered heterocycloalkyl) made up of one or more heteroatoms (e.g., 1, 2, 3 or 4 heteroatoms) selected from N, O and S and with the remaining ring atoms being carbon, and at least one double bond derived by the removal of one molecule of hydrogen from adjacent carbon atoms, adjacent nitrogen atoms, or adjacent carbon and nitrogen atoms of the corresponding heterocycloalkyl. Heterocycloalkenyl groups may be monocyclic or polycyclic (e.g., bicyclic, tricyclic). When nitrogen is present in a heterocycloalkenyl ring, it may, where the nature of the adjacent atoms and groups permits, exist in an oxidized state (i.e.,  $N^+-O^-$ ). Additionally, when sulfur is present in a heterocycloalkenyl ring, it may, where the nature of the adjacent atoms and groups permits, exist in an oxidized state (i.e.,  $S^+-O^-$  or  $-SO_2-$ ). Examples of heterocycloalkenyl groups include dihydrofuranyl (e.g., 2,3-dihydrofuranyl, 2,5-dihydrofuranyl), dihydrothiophenyl (e.g., 2,3-dihydrothiophenyl, 2,5-dihydrothiophenyl), dihydropyrrolyl (e.g., 2,3-dihydro-1*H*-pyrrolyl, 2,5-dihydro-1*H*-pyrrolyl), dihydroimidazolyl (e.g., 2,3-dihydro-1*H*-imidazolyl, 4,5-dihydro-1*H*-imidazolyl), pyranyl, dihydropyranyl (e.g., 3,4-dihydro-2*H*-pyranyl, 3,6-dihydro-2*H*-pyranyl), tetrahydropyridinyl (e.g., 1,2,3,4-tetrahydropyridinyl, 1,2,3,6-tetrahydropyridinyl) and dihydropyridine (e.g., 1,2-dihydropyridine, 1,4-dihydropyridine). In addition, one ring of a polycyclic heterocycloalkenyl group may be aromatic (e.g., aryl or heteroaryl), provided the polycyclic heterocycloalkenyl group is bound to the parent structure via a non-aromatic carbon or nitrogen atom. For example, a 1,2-dihydroquinolin-1-yl group

(wherein the moiety is bound to the parent structure via a non-aromatic nitrogen atom) is considered a heterocycloalkenyl group, while 1,2-dihydroquinolin-8-yl group (wherein the moiety is bound to the parent structure via an aromatic carbon atom) is not considered a heterocycloalkenyl group.

**[033]** By "optional" or "optionally" is meant that the subsequently described event or circumstance may or may not occur, and that the description includes instances where the event or circumstance occurs and instances in which it does not. For example, "optionally substituted alkyl" encompasses both "alkyl" and "substituted alkyl" as defined herein. It will be understood by those skilled in the art, with respect to any group containing one or more substituents, that such groups are not intended to introduce any substitution or substitution patterns that are sterically impractical, synthetically non-feasible, and/or inherently unstable.

**[034]** The term "substituted", as used herein, means that any one or more hydrogens on the designated atom or group is replaced with a selection from the indicated group, provided that the designated atom's normal valence is not exceeded. When a substituent is oxo (i.e., =O) then 2 hydrogens on the atom are replaced. Combinations of substituents and/or variables are permissible only if such combinations result in stable compounds or useful synthetic intermediates. A stable compound or stable structure is meant to imply a compound that is sufficiently robust to survive isolation from a reaction mixture, and subsequent formulation as an agent having at least practical utility. Unless otherwise specified, substituents are named into the core structure. For example, it is to be understood that when (cycloalkyl)alkyl is listed as a possible substituent, the point of attachment of this substituent to the core structure is in the alkyl portion.

**[035]** The terms "substituted"alkyl (including without limitation C<sub>1</sub>-C<sub>4</sub> alkyl), cycloalkyl, cycloalkenyl, aryl, heterocycloalkyl, heterocycloalkenyl, and heteroaryl, unless otherwise expressly defined, refer respectively to alkyl, cycloalkyl, cycloalkenyl, aryl, heterocycloalkyl, heterocycloalkenyl, and heteroaryl, wherein one or more (such as up to 5, for example, up to 3) hydrogen atoms are replaced by a substituent independently chosen from:

**[037]** The term “substituted amino” also refers to the group  $-NR^eR^f$  wherein  $R^e$  and  $R^f$ , together with the nitrogen to which they are bound, form an optionally substituted 5- to 7-membered nitrogen-containing, non-aromatic, heterocycle which optionally contains 1 or 2 additional heteroatoms chosen from nitrogen, oxygen, and sulfur.

**[038]** “Aminocarbonyl” encompasses a group of the formula  $-(C=O)(\text{optionally substituted amino})$  wherein substituted amino is as described herein.

**[039]** Compounds described herein include, but are not limited to, their optical isomers, racemates, and other mixtures thereof. In those situations, the single enantiomers or diastereoisomers, *i.e.*, optically active forms, can be obtained by asymmetric synthesis or by resolution of the racemates. Resolution of the racemates can be accomplished, for example, by conventional methods such as crystallization in

the presence of a resolving agent, or chromatography, using, for example a chiral high- pressure liquid chromatography (HPLC) column. The term “isomers” refers to different compounds that have the same molecular formula. The term “stereoisomers” refers to isomers that differ only in the way the atoms are arranged in space. The term “enantiomers” refers to stereoisomers that are non-superimposable mirror images of each other. A 1:1 mixture of a pair of enantiomers is a “racemic” mixture. The symbol “(±)” may be used to designate a racemic mixture where appropriate. The term “diastereoisomers” refers to stereoisomers that have at least two asymmetric atoms, but which are not mirror-images of each other. The absolute stereochemistry is specified according to the Cahn-Ingold-Prelog *R-S* system. When a compound is a pure enantiomer the stereochemistry at each chiral carbon can be specified by either *R* or *S*. Resolved compounds whose absolute configuration is unknown can be designated (+) or (-) depending on the direction (dextro- or levorotatory) which they rotate plane polarized light at the wavelength of the sodium D line.

**[040]** Where compounds described herein exist in various tautomeric forms, the term “compound” includes all tautomeric forms of the compound. Such compounds also include crystal forms including polymorphs and clathrates. Similarly, the term “salt” includes all tautomeric forms and crystal forms of the compound. The term “tautomers” refers to structurally distinct isomers that interconvert by tautomerization. Tautomerization is a form of isomerization and includes prototropic or proton-shift tautomerization, which is considered a subset of acid-base chemistry. Prototropic tautomerization or proton-shift tautomerization involves the migration of a proton accompanied by changes in bond order, often the interchange of a single bond with an adjacent double bond. Where tautomerization is possible (*e.g.* in solution), a chemical equilibrium of tautomers can be reached. An example of tautomerization is keto-enol tautomerization. A specific example of keto-enol tautomerization is the interconversion of pentane-2,4-dione and 4-hydroxypent-3-en-2-one tautomers. Another example of tautomerization is phenol-keto tautomerization. A specific example of phenol-keto tautomerization is the interconversion of pyridin-4-ol and pyridin-4(1*H*)-one tautomers.

**[041]** Pharmaceutically acceptable forms of the compounds recited herein include pharmaceutically acceptable salts, and mixtures thereof. In some embodiments, the compounds described herein are in the form of pharmaceutically acceptable salts.

[042] “Pharmaceutically acceptable salts” include, but are not limited to salts with inorganic acids, such as hydrochlorate, phosphate, diphosphate, hydrobromate, sulfate, sulfinate, nitrate, and like salts; as well as salts with an organic acid, such as malate, maleate, fumarate, tartrate, succinate, citrate, lactate, methanesulfonate, *p*-toluenesulfonate, 2-hydroxyethylsulfonate, benzoate, salicylate, stearate, haloalkanoate such as trifluoroacetate, and alkanoate such as acetate,  $\text{HOOC}-(\text{CH}_2)_n-\text{COOH}$  where *n* is 0-4, and like salts. Similarly, pharmaceutically acceptable cations include, but are not limited to sodium, potassium, calcium, aluminum, lithium, and ammonium. In addition, if the compounds described herein are obtained as an acid addition salt, the free base can be obtained by basifying a solution of the acid salt. Conversely, if the product is a free base, an addition salt, particularly a pharmaceutically acceptable addition salt, may be produced by dissolving the free base in a suitable organic solvent and treating the solution with an acid, in accordance with conventional procedures for preparing acid addition salts from base compounds. Those skilled in the art will recognize various synthetic methodologies that may be used to prepare non-toxic pharmaceutically acceptable addition salts.

[043] The term “administering”, as used herein in conjunction with a diagnostic agent, such as, for example, a positron-emitter labeled compound described herein, means administering directly into or onto a target tissue or to administer the diagnostic agent systemically to a patient whereby the diagnostic agent is used to image the tissue or a pathology associated with the tissue to which it is targeted. “Administering” a composition may be accomplished by injection, infusion, or by either method in combination with other known techniques.

[044] The term “Curie” (Ci) is a unit of measurement of radioactivity. One Ci refers to that amount of any radioactive material that will decay at a rate of  $3.7 \times 10^{10}$  disintegrations per second. The term “milliCurie” (mCi) refers to  $10^{-3}$  Curie. It is understood that the International System (SI) unit of radioactivity, the Becquerel, is equal to one disintegration/second. Thus one Becquerel =  $2.7 \times 10^{-11}$  Curie.

**[080]** The compounds of Formula I, or a pharmaceutically acceptable salt thereof are labeled with one or more positron-emitting radionuclides. Suitable positron-emitting radionuclides that may be incorporated in the compounds described herein, but are not limited to, <sup>11</sup>C, <sup>13</sup>N, <sup>15</sup>O, <sup>18</sup>F, <sup>52</sup>Fe, <sup>62</sup>Cu, <sup>64</sup>Cu, <sup>68</sup>Ga, <sup>74</sup>As, <sup>82</sup>Rb, <sup>89</sup>Zr, <sup>122</sup>I, and <sup>124</sup>I. In some embodiments, the one or more positron-emitting radionuclides are selected from: <sup>11</sup>C, <sup>13</sup>N, <sup>15</sup>O, <sup>18</sup>F, <sup>76</sup>Br, and <sup>124</sup>I. In some embodiments the one or more positron-emitting radionuclides are selected from <sup>11</sup>C, <sup>13</sup>N, <sup>15</sup>O, and <sup>18</sup>F.

[081] Non-metal radionuclides may be covalently linked to the compounds described herein by a reaction well known from the state of art. When the radionuclide is a metallic positron-emitter, it is understood that labeling may require the use of a chelating agent. Such chelating agents are well known from the state of the art.

[082] A PET imaging agent may be labelled with the positron emitter  $^{11}\text{C}$  or  $^{18}\text{F}$ . Methods for the introduction of  $^{11}\text{C}$  may include, but are not limited to, alkylation with  $^{11}\text{C}$ iodomethane or  $^{11}\text{C}$ methyl triflate. Carbon-11 has a half-life of approximately 20 minutes, thus  $^{11}\text{C}$  needs to be generated in an on-site cyclotron, and is generally produced as  $^{11}\text{C}$ carbon dioxide. The  $^{11}\text{C}$ carbon dioxide is converted to the chemical species appropriate for the radiosynthesis (generally  $^{11}\text{C}$ iodomethane or the like), and the synthesis of the radiopharmaceutical is completed and used on-site in a PET imaging study after the appropriate radiochemical purity and specific activity have been determined. Typical methods of introducing  $^{18}\text{F}$  may include but are not limited to displacement of a halide, tosylate, or other leaving group with  $^{18}\text{F}$ tetrabutylammonium fluoride or  $^{18}\text{F}$ potassium fluoride kryptofix-222. Fluorine-18 has a half life of approximately 110 minutes, thus synthesis of  $^{18}\text{F}$  radiopharmaceuticals need not necessarily have to occur at the site of the cyclotron nor proximal to the PET imaging study center. General methods for the introduction of these positron emitters are described in the literature (Miller et al., *Angewandte Chemie International Edition*, 47 (2008), 8998-9033).

**[089]** Provided herein are compounds having suitable HTT protein aggregate or  $\beta$ -amyloid protein aggregate binding kinetics to function as efficient imaging agents for HTT protein aggregates or  $\beta$ -amyloid protein aggregates. The requirements of the compounds of the invention to function as efficient imaging agents for HTT protein aggregates are: 1) a high affinity for HTT protein aggregates; 2) a low affinity for nearby structures; 3) slow dissociation kinetics from HTT protein aggregates, which may conveniently be expressed as the dissociation rate constant  $k_{\text{diss}}$  as defined in the following equation, wherein A and B refer to the HTT protein aggregate and the imaging agent, and  $k_{\text{assn}}$  is the association rate constant.

$$d[AB]/dt = k_{\text{assn}}[A][B] - k_{\text{diss}}[AB]$$

**[090]** The part of the brain most affected by HD, and thus most likely to contain HTT protein abnormalities, is a group of nerve cells at the base of the brain known collectively as the basal ganglia. The basal ganglia organize muscle-driven movements of the body, or "motor movement." The major components of the basal ganglia are the caudate and the putamen (together known as the striatum) and the globus pallidus (external and internal regions). The substantia nigra and the subthalamic nucleus are often included as part of the basal ganglia as well.

[091] The term basal ganglia, refers to a group of subcortical nuclei responsible primarily for motor control, as well as other roles such as motor learning, executive functions and behaviors, and emotions. Disruption of the basal ganglia network forms the basis for several movement disorders. Normal function of the basal ganglia requires fine tuning of neuronal excitability within each nucleus to determine the exact degree of movement facilitation or inhibition at any given moment. This is mediated by the complex organization of the striatum, where the excitability of medium spiny neurons is controlled by several pre- and postsynaptic mechanisms as well as interneuron activity, and secured by several recurrent or internal basal ganglia circuits. The motor circuit of the basal ganglia has two entry points, the striatum and the subthalamic nucleus, and an output, the globus pallidus pars interna, which connects to the cortex via the motor thalamus.

[092] Provided are methods for imaging part of the brain of an individual involving administering a positron-emitter labeled compound described herein to the individual, *e.g.* into the individual's vascular system, from where it passes through the blood-brain barrier, and then generating an image of at least the part of the individual's brain to which the compound has distributed.

R., Lippincott Williams & Wilkins; 20th edition (Dec. 15, 2000) ISBN 0-912734-04-3 and Pharmaceutical Dosage Forms and Drug Delivery Systems; Ansel, N. C. et al. 7th Edition ISBN 0-683305-72-7.

**[096]** Also provided are uses of positron-emitter labeled compounds described herein for the manufacture of an imaging agent for use in a method of diagnosis of an individual.

**[097]** Provided are methods of generating diagnostic images comprising proton emission tomography (PET). PET involves the administration of a positron-emitting radionuclide tracer to an individual. Once the tracer has had sufficient time to associate with the target of interest, the individual is placed within a scanning device comprising a ring of scintillation detectors. An emitted positron travels through the individual's tissue for a short (isotope-dependent) distance, until it interacts with an electron. The interaction annihilates both the electron and the positron, producing a pair of photons moving in approximately opposite directions. These are detected when they reach a scintillator in the scanning device. Photons that do not arrive in pairs are ignored.

**[098]** Also provided are methods of generating diagnostic images comprising PET with concurrent computed tomography imaging (PET/CT), or with concurrent magnetic resonance imaging (PET/MRI). Computed tomography uses X-rays to show the structure of the brain, while magnetic resonance imaging uses magnetic fields and radio waves.

## EXAMPLES

### General Experimental details

**[0101]** Commercially available reagents and solvents (HPLC grade) were used without further purification. <sup>1</sup>H NMR spectra were recorded on a Bruker DRX 500 MHz spectrometer or a Bruker DPX 250 MHz spectrometer in deuterated solvents. Chemical shifts ( $\delta$ ) are in parts per million. SCX chromatography was performed with Biotage Isolute Flash SCX-2 loading the sample in methanol and eluting with methanol then 5% ammonia in methanol.

**[0102]** Analytical HPLC-MS (METCR1278), was performed on Shimadzu LCMS-2010EV systems using reverse phase Atlantis dC18 columns (3  $\mu$ m, 2.1 X 50 mm), gradient 5-100% B (A = water/ 0.1% formic acid, B = acetonitrile / 0.1% formic acid) over 3 minutes injection volume 3  $\mu$ L, flow = 1.0 mL/minute. UV spectra were recorded at 215 nm using a SPD-M20A photo diode array detector. Mass spectra were obtained over the range m/z 150 to 850 at a sampling rate of 2 scans per second using a LCMS2010EV. Data were integrated and reported using Shimadzu LCMS-Solutions and PsiPort software.

**[0103]** Alternatively, (METCR1416) analytical HPLC-MS on Shimadzu LCMS-2010EV systems using reverse phase Water Atlantis dC18 columns (3  $\mu$ m, 2.1 X 100 mm), gradient 5-100% B (A = water/ 0.1% formic acid, B = acetonitrile / 0.1% formic acid) over 7 minutes, injection volume 3  $\mu$ L, flow = 0.6 mL/minute. UV spectra were recorded at 215 nm using a SPD-M20A photo diode array detector. Mass spectra were obtained over the range m/z 150 to 850 at a sampling rate of 2 scans per second using a LCMS2010EV. Data were integrated and reported using Shimadzu LCMS-Solutions and PsiPort software.

**[0104]** Alternatively, (MET-uHPLC-AB-101) analytical HPLC-MS were performed on a Waters Acquity UPLC system with Waters PDA and ELS detectors using a Phenomenex Kinetex-XB C-18 column, (1.7  $\mu$ m, 2.1 mm X 100 mm at a column temperature of 40 °C, gradient 5-100% B (A = water / 0.1% formic acid; B = acetonitrile / 0.1% formic acid) over 5.3 minutes, then 100% B for 0.5 minute, flow = 0.6 mL/minute. UV spectra were recorded at 215 nm using a Waters Acquity photo diode array. Mass spectra were obtained over the range m/z 150 to 850 at a sampling rate of 5 scans per second using a Waters SQD. Data were integrated and reported using Waters MassLynx and OpenLynx software.

**[0105]** All example compounds display an LC purity of >95% unless stated otherwise.

**Step 1, Method 1: 2-(5-Fluoro-1-benzofuran-2-yl)-N-methylimidazo[1,2-a]pyridin-3-amine**

**[0106]** To a solution of pyridin-2-amine (0.20 g, 2 mmol) and 5-fluorobenzofuran-2-carboxaldehyde (0.35 g, 2 mmol) in methanol (10 mL) was added methyl isocyanide (0.09 mL, 1.9 mmol), followed by acetic acid (0.5 mL). The reaction was stirred at room temperature for 4 days. 1 M sodium hydroxide (5 mL) was added and the methanol was evaporated. Water (10 mL) was added, the mixture washed with ethyl acetate and acidified with 1 M hydrochloric acid. The precipitate was filtered off, and then washed with water and ethyl acetate to give the title compound 0.26 g (46% yield) as a yellow solid.

#### Q46 Radioligand Binding Assay

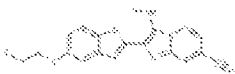

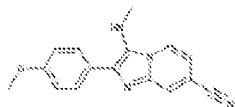

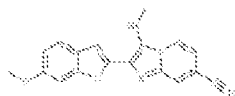

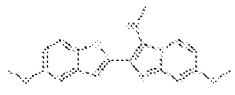

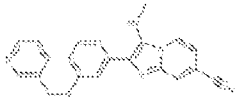

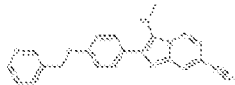

[0197] For radioligand binding assays (RBA) GST-Q46 protein was generated based on a previous publication (Scherzinger et al. Cell, Vol. 90, 549–558, August 8, 1997). For experiments 33  $\mu$ M GST-Q46 was incubated with 150  $\mu$ g/mL thrombin in assay buffer (150 mM NaCl, 50 mM Tris pH 8.0) and 2 mM CaCl<sub>2</sub> for 16 hours at 37 °C. Aggregated Q46 was pelleted by centrifugation for 5 minutes at 13,000 rpm in a bench top centrifuge and re-dissolved in the same volume of assay buffer. Test compounds were prepared by titration in DMSO at 11 concentrations from 33  $\mu$ M to 1 nM. For the RBA, Q46 protein aggregates and test compounds were pre-incubated in assay buffer for 20 minutes at room temperature, in 140  $\mu$ L/well in a 96-well plate (pp, round bottom). Then, ligand was added in 10  $\mu$ L/well and incubated for 60 minutes at 37 °C. Final assay concentrations were 1  $\mu$ M to 30 pM test compound, 5  $\mu$ M Q46 protein (equivalent monomer concentration) and 10 nM ligand [<sup>3</sup>H<sub>3</sub>]MK-3328 (Harrison et al., *ACS Med. Chem. Lett.*, 2 (2011), pp 498–502). Samples were transferred onto GF/B filter plates and washed 2 x with 200  $\mu$ L PBS using a Filtermate Harvester. After drying filter plates for 1 hour at 37 °C, the back of the plates was sealed with foil and 30  $\mu$ L/well scintillation fluid (Packard MicroScint 40) was added, incubated for 15 minutes in the dark and counted in a

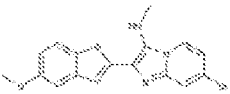

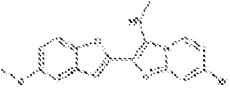

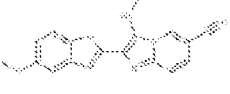

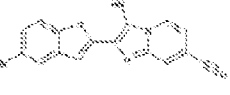

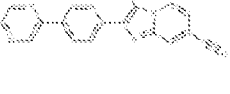

TopCount reader. For analysis, replicate data from independent assay plates were normalized towards 0% and 100% inhibition using control wells of vehicle (0% inhibition) and 3  $\mu$ M unlabelled MK-3328 (100% inhibition). IC<sub>50</sub> values were determined with a sigmoidal inhibition model with four variables (top, bottom, slope, IC<sub>50</sub>) in a global fit using the normalized replicate data.
