Title: SYSTEM AND METHOD FOR BACKGROUND DOWNLOAD OF DIGITAL CONTENT TO AN INTERMITTENTLY CONNECTED PERIPHERAL DEVICE VIA A WIRELESS DEVICE

Abstract: A system and method for downloading graphical images to a display device from a server through a wireless communication network within a predetermined time interval. In one embodiment, a docking station for a wireless device is provided with a connector for connecting the display device, and docking station provides a dial tone to the display device within the predetermined time interval and requests connection to the server through the wireless device. The docking station will not provide the dial tone outside of the predetermined time interval.

SYSTEM AND METHOD FOR BACKGROUND DOWNLOAD OF DIGITAL CONTENT TO AN INTERMITTENTLY CONNECTED PERIPHERAL DEVICE VIA A WIRELESS DEVICE

BACKGROUND OF THE INVENTION

[0001] The present invention generally relates to wireless telecommunication. More specifically, the present invention relates to a system and method for delivering digital content to a wireless telecommunication device intermittently connected to a peripheral device.

DESCRIPTION OF THE RELATED ART

[0002] The variety of wireless telecommunication devices is increasing with cellular telephones, personal digital assistants (PDAs), pagers, and other voice and data devices accessing terrestrial wireless networks. To attract new customers, wireless service providers offer significant amounts of airtime and many people have taken advantage of these offers such that the persons have forgone the traditional landline based telephones and used the wireless telephones as their primary telecommunications devices. Because of this initial surplus of airtime, the consumers have begun to use wireless telecommunications devices as a medium for data transfer, namely downloading data from a server to their computers or other computer appliances. This shift in consumer behavior has increased traffic volume in wireless communications network and slowed down the overall voice and data traffic, especially during peak network time usage.

[0003] The wireless service providers attempted to address the problem of increased usage by increasing the wireless network capacity, which is expensive, and encouraging more use of network at off peak time by offering cheaper connection fees and minutes during the off peak period. However, these attempts at modifying consumer behavior to use off-peak airtime have mostly been unsuccessful. Most consumers still connect to the wireless network during daytime, peak hours and few people are willing to take advantage of low traffic, nighttime hours of the wireless network.

[0004] There exist devices that are developed to take advantage of low traffic in a traditional land-based telephone network by automatically dialing a telephone number at a predefined hour, but these devices cannot interface with wireless devices. There are also other telecommunication devices that attempt to arbitrage the communication rates, typically for long-distance telephone rates, and transfer data across telephone lines at the most favorite rate.
Accordingly, it would be advantageous to provide a system and method that allows wireless device users to transfer data at least partially across a wireless network during low traffic volume hours. It is thus to such a system and method that the present invention is primarily directed.

SUMMARY OF THE INVENTION

The present invention is an apparatus and method that allow the use of a wireless telecommunication device, such as a wireless telephone, for downloading graphical images to a display device during a predetermined, off-peak interval when the traffic volume on a wireless network is low. In one embodiment, the present invention is a device, such as a docking station, that has a wireless device interface, a timing circuit, a telephone number detector, a dial tone generator, and a controller. The device, at a predetermined time, provides a dial tone to the display device and receives destination telephone information from the display device. The destination telephone number is typically associated to a server. The predetermined time usually is when the wireless network traffic volume is low, such as in the middle of the night, and the device will not provide the dial tone outside of the predetermined time. After receiving the destination telephone number, the device sends the destination telephone number to the wireless device and requests the wireless device to establish a connection across the wireless network with the destination telephone number. After the destination telephone number answers, the device establishes a connection between the wireless device and the display device, and the display device then proceeds to download the graphical images from the server.

In another embodiment, the present invention is a device that has a transceiver, a timing circuit, a controller, a storage unit, and a display unit. The device can connect to a remote server through a wireless network and download graphical images from the remote server. The device communicates with the wireless network and transmits a destination telephone number via its transceiver. After connecting to the remote server, the device downloads the graphical images and stores them in the storage unit for sequential display at the display unit. The apparatus communicates with the wireless network within a predetermined time window when the wireless network has a low traffic volume.

In a further embodiment, the present invention is a device that has a display device, a docking station interface, a controller, and a storage unit. The device connects
to a docking station and receives graphical images from the docking station for display
at the display device.

[0009] Other objects, advantages, and features of the present invention will become
apparent after review of the hereinafter set forth Brief Description of the Drawings,
Detailed Description of the Invention, and the Claims.

DETAILED DESCRIPTION OF THE INVENTION

[0022] In this description, the terms “communication device,” “wireless device,”
“wireless telephone,” “wireless communications device,” and “wireless handset” are
used interchangeably, and the term “application” as used herein is intended to
ecompass executable and nonexecutable software files, raw data, aggregated data,
patches, and other code segments. Further, like numerals refer to like elements
throughout the several views. With advent of 3rd generation (3G) wireless
communication technology, more bandwidth has become available for wireless
communications, and handsets and wireless telecommunication devices, such as cellular
telephones, pagers, personal digital assistants (PDAs) have increasing wireless
capabilities.
[0023] Fig. 1 depicts a prior art cellular telecommunication network 100. The communication network 100 includes one or more communication towers 106, each connected to a base station (BS) 110 and serving users with communication devices 102. The communication devices 106 can be cellular telephones, pagers, personal digital assistants (PDAs), laptop computers, or other hand-held, stationary, or portable communication devices that use a wireless and cellular telecommunication network. The commands and data input by each user are transmitted as digital data to a communication tower 106. The communication between a user using a communication device 102 and the communication tower 106 can be based on different technologies, such as code division multiplexed access (CDMA), time division multiplexed access (TDMA), frequency division multiplexed access (FDMA), the global system for mobile communications (GSM), or other protocols that may be used in a wireless communications network or a data communications network. The data from each user is sent from the communication tower 106 to a base station (BS) 110, and forwarded to a mobile switching center (MSC) 114, which can be connected to a public switched telephone network (PSTN) 118 and the Internet 120.

[0024] The MSC 113 may be connected to a server 116 that supports different applications available to subscribers using the wireless communications devices 102. Optionally, the server 116 can be part of the MSC 113. The server 116 can be operated by the wireless service supplier or a third party. The server 116 stores graphical images that can be downloaded by wireless subscribers. The wireless subscribers can be identified by mobile identification number (MIN) or the wireless device’s electronic identification number (EIN).

[0025] Fig. 2 is an architecture 200 of an embodiment of the graphical display. A display device 206 is connected to a docking station 202 for a wireless telephone 102. The docking station 202 is also connected to a power outlet 204 and charges the battery of the wireless telephone 102. In addition to providing charge to the battery, the docking station 202 connects the display device 206 to the wireless telephone 102 in data transfer interconnection. The wireless telephone 102 accordingly provides wireless communications to the communication tower 106.

[0026] The display device 206 can be a picture frame capable of displaying digital graphical images, such as Digital Photo Receiver from Ceiva™. The display device 206 can be connected to the docking station 202 with a twisted pair telephone line, other cable, or other data connectors, such as Universal Serial Bus (USB) connectors. The
docking station 202 has a female RJ-11 connector for receiving the telephone line from the display device 206. Alternatively, the docking station 202 can be equipped with USB connector, serial bus connector, parallel bus connector, or other data connectors. In this embodiment, the docking station 202 provides communication between the display apparatus 206 and the wireless telephone 102.

[0027] Fig. 3 illustrates an embodiment of the system where a display device 306 equipped with a wireless transceiver is used. In this embodiment, the display device 306 communicates directly through wireless transmission with a communication tower 106. The display device 306 dials a destination telephone associated with a server 116 and establishes connection with the server 116 through the wireless communication network. The graphical images are downloaded directly from the server 116 to the display device 306 through the wireless communications network.

[0028] Fig. 4 illustrates an architecture 400 of an embodiment of a docking station 202. The docking station 202 has a controller 401, a power module 402, a dial tone generator 404, a telephone number detector 406, timing circuit 408, and a wireless device interface 410. The power module 402 allows the docking station 202 to work as a charging station for the wireless telephone 102. The dial tone generator 404 provides a dial tone to a RJ-11 jack 414.

[0029] However, before providing the dial tone to the RJ-11 jack 414, the controller 401 checks with the timing circuit 408 whether the present time is within a predefined period. The docking station 202 only provides the dial tone to the RJ-11 jack 414 within the predefined period. This prevents the display device 206 from connecting to the wireless telecommunications network outside of the predefined period. The predefined or predetermined period can be set by the user, and is typically between 10 PM and 5 AM when the wireless telecommunications network has low traffic volume.

[0030] If the display device 206 requests access to the server 116 during the predetermined period, the docking station 202 provides the connection to the wireless telecommunications network. The display device 206 equipped with dialing capability can connect to the docking station 202 via the RJ-11 jack 414. The docking station 202 provides a voltage, typically 48 volts, to the RJ-11 and can detect the drop in voltage when the display apparatus 206 connected to the RJ-11 is "off-hook." When the display device 206 goes "off-hook," the dial tone generator 404 generates a dial tone to the display device 206.
When the dial tone becomes available to the display device 206, the display device 206 proceeds to dial a destination telephone number. The dialed number is received by the docking station 202 and processed by the telephone number detector unit 406. The telephone number detector unit 406 verifies whether the number received within a predetermined period form a recognizable destination telephone number. If the telephone number received within the predefined period has 7, 9, or 10 digits and follows the North American Numbering Plan (NANP), the telephone number is sent to the wireless device interface unit 410. The wireless device interface unit 410 communicates with the wireless telephone 102 through a predefined protocol and forwards the telephone number received from the display device 206 to the wireless telephone 102. The wireless telephone 102 receives the telephone number and requests connection to the telephone number via the wireless network.

Fig. 5 is a flow chart 500 for a connection process using the docking station 202 of Fig. 4. The docking station 202 checks the present time is within the predefined period, step 501, whether the wireless telephone is in the cradle and idle, i.e., docked in the docking station 202, step 502, and finally whether the display device 206 is attempting to dial out, i.e., gone “off-hook,” step 503. If all the above tests are true, then the docking station 202 provides a dial tone, step 504, to the display device 206.

After a number is received from the display device 206, step 506, the docking station 202 checks whether the number is a telephone number, step 508. If it is not a telephone number, the docking station provides an error signal to the display device, step 510. The error signal can be a busy signal to the RJ-11 jack. After providing the error signal, the docking station 202 checks whether the display device 206 has hung up, step 512. The docking station 202 continues to provide the error signal until the display device 206 hangs up.

If the number received is a telephone number, the docking station 202 sends the number to the wireless telephone 102 for dialing, step 514. After the wireless telephone 102 dials the telephone number and establishes a connection with the server, the docking station 202 connects the wireless telephone with the display device, step 516, and monitors the connection, step 518. The docking station 202 continuously checks whether the connection has ended, step 520. When the connection has ended, the docking station breaks the connection between the wireless telephone 102 and the display device 206.
Fig. 6 illustrates an architecture 600 of an embodiment of a display device 206. The display device 206 has a display unit 602, a storage unit 604, a controller 606, a docking station interface unit 608, and an external connector 610. The display device 206 connects to a docking station and serves as an extended storage place for graphical images. The connection may be done via a USB, a serial port, a parallel port, or any other means for connecting computing devices. After the connection is made, the display device 206 can receive graphical images from the docking station, and the graphical images are stored in the storage unit 604. The controller 606 will then control the display of the images on the display unit 602.

The display device of Fig. 6 does not require extended features because it relies on the docking station for determining when and how to connect to a server. The display device 206 of Fig. 6 accordingly performs only storage and display functions.

Fig. 7 is a flow chart 700 for a connection process for a docking station connected to the display device of Fig. 6. The docking station checks whether the wireless handset is docked, step 702, whether the current time is the preset time, step 704, and whether the display device is connected, step 706, before dialing the server, step 708. After connecting to the server, step 710, the docking station provides user identification information to the server, step 712. The server verifies the user is a subscriber and then sends graphical images to the docking station via wireless transmission. The docking station receives the graphical image data, step 714, and sends it to the display device for storage, step 716.

Fig. 8 is a flow chart 800 for the display device of Fig. 6. The display device checks whether there is any incoming graphical image data, step 802. If the display device is connected to the docking station and receiving graphical images, the display device receives graphical image data, step 804, and stores the data in the storage unit 604, step 806. The display device continues to receive and store the data until there is no more incoming data.

After receiving incoming data, the controller 606 retrieves an image from the storage unit 604, step 808, resets a timer, step 810, and displays the image on the display unit 602. The image is displayed for a predetermined period. When the timer expires, step 814, the controller 606 repeats the cycle by first checking whether there is incoming data, then retrieving next image for display.

Fig. 9 is architecture 900 of the display device 306 shown in Fig. 3. The display device 306 has a controller 902, a storage unit 904, a display unit 906, a timing
circuit 908, a user interface 910, and a transceiver 912. The display device 306 is capable of initiating a wireless call to a server by connecting to a wireless network and transmitting a destination telephone number via the transceiver 912. The user can set the destination telephone number and a predefined period for connecting to the server through the user interface 910. The display device 306 then only makes the connection to the server within the predefined period.

[0041] Fig. 10 is a flow chart 1000 for displaying graphical images on the display device of Fig. 9. The controller 902 retrieves an image from the storage unit 604, step 1002, resets the timer, step 1004, and sends the image to the display unit 906 for display, step 1006. When the timer expires, step 1008, a new graphical image is retrieved and displayed.

[0042] Fig. 11 is a flow chart 1100 for downloading graphical images by the display device of Fig. 9. The display device determines whether it is time to connect to the server for downloading graphical image data, step 1101. If it is the predetermined time, the display device retrieves the destination telephone number for the server and dials the server, step 1102. After connecting to the server, step 1104, the display device provides identification information, step 1106, to the server. After the server verifies that the display device belongs to a subscriber, the server transmits graphical image data to the display device. The display device receives the data, step 1108, and stores the data in the storage unit 904, step 1110. After receiving the data, the display device disconnects from the server, step 1112.

[0043] Fig. 12 is an illustration of another embodiment of the system. In this embodiment 1200 the display device has a built-in wireless telephone docking and charging station. The display/docking station 1200 has a cradle for charging a wireless telephone and a display device for displaying graphical images. The apparatus 1200 can dial the server via the wireless telephone, receive the graphical images, and display the graphical images on the attached display unit.

[0044] The following is a description of a use scenario for the present invention. A user purchases a display device 206 and a docking station 202 and subscribes to a picture downloading service from a service provider. The picture downloading service can be provided by a wireless service provider or an independent third party. A user identification number and/or a password is assigned to the user. The docking station 202 can serve as a battery charging station for user's wireless telephone.
[0045] The user programs the docking station 202 so that the docking station 202 allows an intermittently connected peripheral, such as the display device 206, to dial out through the wireless telephone only during a predefined period, such as from 10:00 PM to 5:00 AM. Any attempt to connect to the wireless network outside of the predefined period will fail.

[0046] The user programs a destination telephone number associated with the service provider into the display device 206, and the user can also set a predefined period for connecting to the service provider. Finally, the user connects the display device 206 to the docking station 202. Friends and relatives of the user can upload pictures to a server belonging to the service provider and these pictures will then be available for user to download at user’s convenience.

[0047] Generally, the user carries the wireless device 102 during the daytime, and at nighttime the wireless device 102 is placed in the docking station 202 to charge the battery. While the wireless device 102 is charging its battery and the traffic volume of the wireless network is low, the display device 206, or other peripheral, takes advantage of this low traffic, and possibly low connection fee time, to connect to the server for downloading new pictures.

[0048] At the predetermined time, the display apparatus goes “off-hook,” and checks for dial tone. The docking station 202, upon detecting the display device 206 has gone off-hook and verifying the time and the availability of the wireless device 102, provides the dial tone and waits for a dialed telephone number. After collecting digits for a predetermined period, the docking station checks whether the collected digits are a telephone number.

[0049] If the display device 206 goes off-hook outside of the predefined period, the docking station 202 will not provide the dial done, and the display device 206 will not be able to connect to the server.

[0050] After verifying the digits are a telephone number, the docking station 202 checks whether the wireless telephone is docked. If the wireless device 102 is docked, the docking station 202 sends the telephone number to the wireless device 102 and requests a connection. The wireless device 102 dials the telephone number associated with the server and connects the server with the docking station 202. The docking station 202 opens a path between the wireless device 102 and the display device 206, and the display device 206 then proceeds to request pictures for downloading.
After downloading the pictures, the display device 206 hangs up. The hang up is detected by the docking station 202, and the docking station 202 proceeds to send a hang up signal to the wireless device 102. The display device 206 proceeds to display the pictures sequentially.

In view of the method being executable on a wireless service provider’s computer device or a wireless communications device, the present invention includes a program resident in a computer readable medium, where the program directs a server or other computer device having a computer platform to perform the steps of the method. The computer readable medium can be the memory of the server, or can be in a connective database. Further, the computer readable medium can be in a secondary storage media that is loadable onto a wireless communications device computer platform, such as a magnetic disk or tape, optical disk, hard disk, flash memory, or other storage media as is known in the art.

In the context of the invention, the method may be implemented, for example, by operating portion(s) of the wireless network to execute a sequence of machine-readable instructions, such as wireless communications device or the server. The instructions can reside in various types of signal-bearing or data storage primary, secondary, or tertiary media. The media may comprise, for example, RAM (not shown) accessible by, or residing within, the components of the wireless network. Whether contained in RAM, a diskette, or other secondary storage media, the instructions may be stored on a variety of machine-readable data storage media, such as DASD storage (e.g., a conventional “hard drive” or a RAID array), magnetic tape, electronic read-only memory (e.g., ROM, EPROM, or EEPROM), flash memory cards, an optical storage device (e.g. CD-ROM, WORM, DVD, digital optical tape), paper “punch” cards, or other suitable data storage media including digital and analog transmission media.

While the invention has been particularly shown and described with reference to a preferred embodiment thereof, it will be understood by those skilled in the art that various changes in form and detail maybe made without departing from the spirit and scope of the present invention as set for the in the following claims. Furthermore, although elements of the invention may be described or claimed in the singular, the plural is contemplated unless limitation to the singular is explicitly stated.
What is claimed is:

1. A docking station for connecting a display device to a server through a wireless communication connection, wherein the docking station interfaces with a wireless device, and the display device being connected to the docking station and being capable of placing a call to the server through a public switched telephone network, the docking station further selectively permitting the display device to call the server only during a predetermined period of time.

2. The docking station of claim 1, further comprising a dial tone generator, wherein the dial tone generator provides a dial tone to the display device.

3. The docking station of claim 1, further comprising a telephone number detector, the telephone number detector receiving dialed number information from the display device and checking for a destination telephone number.

4. The docking station of claim 1, further comprising a timing circuit, wherein a preset time is stored.

5. The docking station of claim 4, further comprising a controller, wherein the controller checks the timing circuit to determine whether to send a destination telephone number to the wireless device.

6. The docking station of claim 1, further comprising a wireless device interface module, the wireless device interface module having a connection to the wireless device, wherein the wireless device interface receives a destination telephone number and transmits the destination telephone number to the wireless device.

7. The docking station of claim 1, further comprising a power module, wherein the power module provides electricity for charging a battery in the wireless device.

8. The docking station of claim 1, further comprising a connector for providing connection to the display apparatus.
9. The docking station of claim 8, wherein the connector is a telephone connector.

10. A method for connecting a display device to a server at a predetermined time and receiving graphical images from the server for displaying by the display device, comprising:
    a step for receiving a destination telephone number associated with the server;
    a step for checking if current time is within a predetermined time interval;
    if the current time is within the predetermined time interval, a step for transmitting the destination telephone number to a wireless device;
    a step for requesting the wireless device to dial the destination telephone number;
    a step for receiving the graphical images through the wireless device; and
    a step for transmitting the graphical images to the display device.

11. The method of claim 10, further comprising a step for receiving a predetermined time interval from a user.

12. The method of claim 10, further comprising a step for verifying that the wireless device is connected to a docking station.

13. The method of claim 10, further comprising a step for verifying that the wireless device is idle.

14. The method of claim 12, further comprising a step for, if the wireless device is connected to the docking station and idle, providing a dial tone to the display device.

15. The method of claim 10, further comprising:
    if the current time is not the predetermined time interval, a step for generating a busy signal; and
    a step for transmitting the busy signal to the display device.
16. The method of claim 10, further comprising a step for verifying the destination telephone number is a recognizable telephone number.

17. An apparatus for receiving graphical images from a wireless network and displaying the data received, comprising:
   means for storing a predetermined time interval received from a user;
   means for transmitting a destination telephone number to the wireless network and for receiving the graphical images from the wireless network;
   means for storing the graphical images received from the wireless network; and
   means for displaying the graphical images received from the wireless network during the stored predetermined time interval.

18. The apparatus of claim 17, further comprising means for receiving instructions from the user.

19. A method for receiving graphical images through wireless transmission from a server in communication with a wireless network and displaying the graphical images on a display device, wherein the graphical images are transmitted during a predetermined time interval, comprising:
   a step for receiving information indicating the predetermined time interval;
   a step for receiving a destination telephone number;
   if current time is the predetermined time, a step for connecting to the destination telephone number via a wireless telephone network;
   a step for receiving the graphical images; and
   a step for displaying the graphical images.

20. The method of claim 19, further comprising a step for transmitting the destination telephone number via wireless communication to the wireless network.

21. A computer program stored in a computer readable medium that, when executed by a computer device connectively couples a display device to a wireless device, causes the computer device to perform the steps of:
   receiving a destination telephone number associated with the server;
   checking if current time is within a predetermined time interval;
if the current time is within the predetermined time interval, transmitting the
destination telephone number to a wireless device;
requesting the wireless device to dial the destination telephone number;
receiving the graphical images through the wireless device; and
transmitting the graphical images to the display device.

22. The computer program of claim 21, further causing the computer device
to perform the step of receiving a predetermined time interval from a user.

23. The computer program of claim 21, further causing the computer device
to perform the step of verifying that the wireless device is connected to a docking
station.

24. The computer program of claim 21, further causing the computer device
to perform the step of verifying that the wireless device is idle.

25. The computer program of claim 22, further causing the computer device
to perform the step of, if the wireless device is connected to the docking station and idle,
providing a dial tone to the display device.

26. The computer program of claim 21, further causing the computer device
to perform the step of:
if the current time is not the predetermined time interval, generating a busy
signal; and
transmitting the busy signal to the display device.

27. The computer program of claim 21, further causing the computer device
to perform the step of verifying the destination telephone number is a recognizable
telephone number.
