There is disclosed herein a bipolar fetal monitoring electrode having an electrode body (12a), a spiral electrode (13) terminating in a point for engaging with fetal scalp, and a reference electrode (14) insulated from the spiral electrode. The end of the electrode from which the spiral extends includes one or more protrusions (22, 24) in the form of points, ramps, ribs or the like to increase the resistance of the spiral from unwinding from fetal scalp to which it is attached and thus to help prevent the spiral from unwinding spontaneously.

DESCRIPTION

Spiral Electrode With Contact Retainer

Background

The present invention relates to a bipolar electrode structure particularly suitable for use in fetal heart monitoring.

Various forms of monitoring electrode structures have been developed. These include, for example, a body organ electrode shown in U.S. Patent No. 3,416,534 which is arranged for insertion into the body through a hypodermic needle and to function as a pacemaker electrode, and a similar type shown in U.S. Patent No. 3,472,234. Both of these electrodes have a spiral configuration for attachment to a body organ. Other examples are the implantable electrode shown in Patent No. 3,737,779, and the double spiral fetal electrode shown in Patent No. 3,770,650.

A type of electrode to which the present invention is particularly directed is shown in greater detail in applicant's U.S. Patent No. 3,890,420 and No. 3,910,271, and in Figures 8-10 of Hon U.S. Patent No. Re. 28,990.

Figure 1 of the present application illustrates this form of prior art electrode which comprises a bipolar electrode formed by injection molding to form a body 12 having a first spiral electrode 13 at the forward end thereof and a second wafer electrode 14 at the rear end thereof. The first and second electrodes 13 and 14 are made of a conductive metal such as stainless steel or the like, and each is respectively connected to first and second insulated wire conductors 15 and 16. The exposed surface of the wafer electrode 14 generally is approximately twice the exposed surface area of the electrode 13. The other ends of the conductors 17 and 16 are connected in a manner well known in the art to electronic monitoring equipment (not shown) suitable for monitoring fetal heartbeat, heart
rate or the like. U.S. Patent No. 3,890,420 discloses a method and molding apparatus for forming the electrode structure of Figure 1.

The spiral electrode of the type shown in Figure 1 has been widely accepted and has overcome the various problems of the "forceps-endoscope" and the "sliding sleeve-clip" type of electrodes, both of which include clips but which must be squeezed onto the fetal epidermis. The spiral electrode of Figure 1, on the other hand, can be readily easily inserted through the vagina and cervix of a woman in labor or about to be in labor by suitable applying devices of the nature shown in No. 3,910,271 and Re. 28,990 and, thus, in many instances can be quickly and effectively applied to the fetus during an early stage of labor, and which can be quickly and easily removed.

However, it has been found through years of use of the form of spiral electrode of the type shown in Figure 1 that the doctor will apply one electrode by screwing into the fetal epidermis, but in many instances it comes off and a second one (and sometimes even more) must be applied. It generally is too cumbersome to attempt to reapply a first electrode which has become detached and, thus, that electrode usually is removed and another electrode applied. Because of the nature of the spiral, and the "lead" or angle of the spiral 13, there is a tendency for the spiral to unwind or unscrew itself spontaneously or inadvertently from the fetal scalp after being connected to the fetal scalp by the doctor. This not only necessitates one or more additional electrodes to be tried, but also results in undue trauma to the fetal scalp.

The present invention involves a modification of a portion of the spiral electrode of the type shown in Figure 1 so as to provide improved frictional contact between a surface of the electrode and the fetal skin to thereby minimize the opportunity for the spiral to unwind itself. According to exemplary embodiments of the present
invention, the surface of the spiral electrode which is to contact the fetal scalp is provided with protrusions in the form of, for example, points, ribs, ramps or the like to cause added friction or interference, or to gather scalp, so as to reduce or minimize the possibility for the spiral to unwind or unscrew spontaneously or inadvertently from the scalp.

Accordingly, it is a principal object of the present invention to provide an improved form of spiral electrode.

Another object of this invention is to provide a spiral electrode wherein the end that contacts skin is modified to increase the friction or interference between the electrode and the skin so as to minimize loosening or unwinding of the electrode from the skin.

A further object of this invention is to provide a new form of fetal monitoring spiral electrode having protrusions in the form of, for example, a plurality of points, ramps, ribs or the like, molded in the surface of the electrode which contacts the skin so as to minimize inadvertent detachment of the electrode from the skin.

These and other objects and advantages of the present invention will become better understood through a consideration of the following description, taken in conjunction with the drawings in which:

In The Drawings

Figure 1 is a perspective view of a conventional prior art fetal monitoring spiral electrode;

Figure 2a is a side elevational view and Figure 2b is a partial top plan view of a first embodiment of a modified spiral electrode according to the present invention including protrusions in the form of points molded as part of the electrode,

Figure 3a is a side elevational view and Figure 3b is a partial top plan view illustrating another embodiment with protrusions in the form of points molded as part of the electrode, and
Figure 4a is a side elevational view and Figure 4b is a partial plan view of a third embodiment of an electrode having protrusions in the form of thin ribs molded as part of the electrode.

Turning now to the drawings, and again to the prior art electrode in Figure 1, the spiral 13 and wafer 14 electrodes are molded into the electrode body 12 as previously discussed and as more fully described in, for example, Patent No. 3,890,420. The electrode of Figure 1 includes the cylindrical plastic body 12 which has a first, proximal end 18 and a second, distal end 19. The spiral 13 of the electrode is pointed at 20 and when it is screwed into the fetal scalp, the first end 18 of the body 12 normally, at least initially, is adjacent the skin, and the second end 19 is disposed away from the fetal scalp. Because of the "lead" or angle (like screw threads) of the spiral 13 as noted earlier, there is a tendency for the electrode to unwind or unscrew spontaneously from the fetal scalp.

Turning now to the exemplary embodiments shown in Figures 2-4, like parts bear like or similar reference numerals to those in Figure 1. Thus, in each of Figures 2 through 4 an injection molded electrode body is illustrated at 12a, and a spiral electrode 13, a wafer electrode 14, and one of the electrical conductors 15 are all shown (the spiral 13 is partially omitted from Figs. 2b, 3b and 4b for clarity). A different reference numeral 12a is used for the plastic body of the electrode because a first, distal end 18a thereof is modified according to the present invention from the conventional electrode of Figure 1. In each instance, the first surface 18a which confronts the skin of the fetus is modified in a manner to increase the friction or resistance, or to provide fetal skin gathering ability, so as to prevent or minimize spontaneous unwinding of the spiral 13 from the fetal skin.
In the arrangement shown in Figures 2a-2b, first and second protrusions in the form of right angle points 22 and 24 are provided. These preferably are molded into the body 12a during molding of the electrode. The points 22 and 24 are basically right angle triangular in shape, with first surfaces 22a and 24a essentially parallel to the longitudinal axis of the electrode, and second surfaces 22b and 24b being inclined downwardly toward the surface 18a from the respective apex 22c and 24c of the points. The heights of the points 22 and 24 typically may range from approximately .015 to .020 inch as illustrated in Figure 2a, with 22 being shorter than 24 so as to maintain about an equal distance between the apexes 22c and 24c of these points and the spiral 13 (see Fig. 2a). Thus, the height difference of the points essentially is varied as the angle of the spiral 13. The points 22 and 24 may extend from the outer periphery 26 (note Figure 2b) radially inwardly partially toward the center of the surface 18a as best seen in Figure 2b.

These points 22 and 24 molded as part of the electrode with one straight side (22a, 24a) serve to minimize the opportunity for the spiral to spontaneously unwind itself. However, the spiral can be readily easily removed from the fetal scalp by slightly pulling the electrode away from the scalp and unwinding the electrode. The points 22 and 24 thus act as an impediment to unscrewing the electrode from the fetal scalp by essentially digging into the flexible scalp or serving to gather the skin between points to thereby increase the friction between the surface 18a and the scalp.

The embodiment shown in Figures 3a-3b is similar to that shown in Figures 2a-2b, but in this case, protrusions in the form of points 32 and 34 are essentially in the form of forty-five degree triangles (when viewed from the periphery of the electrode as seen in Figure 3a, thereby forming inclined sides (32a, 34a, and 32b, 34b) having an included angle of forty-five degrees extending to
respective apexes 32c and 34c. As in the embodiment of Figure 2, the points 32 and 34 can extend from the periphery 26 of the electrode body 12a radially toward the center on the surface 18a as best seen in Figure 3b. The points 32 and 34 help to gather the scalp between these points so as to minimize the opportunity for the spiral to unwind spontaneously. A typical height for the ribs 32 and 34 ranges from .010 to .017 inch as shown in Figure 3a, with the rib 32 being the shorter and rib 34 being the taller.

Turning now to the embodiment of Figures 4a-4b, the same illustrates a pair of relatively thin ribs 42 and 44. In this embodiment, these ribs are rectangular as shown in Figure 4 and extend radially from the periphery 26 toward the center of the surface 18a. The tops 42c and 44c can be flat as shown and substantially parallel to the surface 18a. A typical thickness for these ribs is approximately .010 inch wide, with the height of the two ribs 42 and 44 varying from approximately .010 to .017 inch as shown in Figure 4a. These thin ribs 42 and 44 cause interference to help keep the spiral from unwinding spontaneously. These ribs can be slightly flexible so as to bend and help to lock the scalp between the wire spiral 13 and the surface or base 18a.

The protrusions, such as the points and ribs as shown in Figures 2 through 4, help to increase the friction or interference between the electrode body 12a and the fetal skin either through their "roughness" to increase friction or interference, or through gathering fetal skin between the points or ribs, and along with the slight resilience of the spiral 13 to thus help minimize unwinding of the spiral 13. On the other hand, the electrodes still can be easily removed when necessary by pulling slightly on the conductors (e.g., 15 and 16) in a direction away from the fetal scalp (toward the bottom of the drawings in Figures 2a, 3a and 4a) which helps pull the protrusions away from the skin because of the resilience of the spiral 13.
Because of this action, including the slight flexibility of the spiral 13, the interference or resistance is reduced to thereby allow the spiral 13 to be unscrewed upon demand (e.g., after delivery) in a manner already well familiar to physicians.

While specific exemplary embodiments of configurations of points, ramps, ribs and the like have been shown and discussed, it will be apparent to those skilled in the art that the shapes, numbers, widths, lengths, and the like of these protrusions from the base or surface 18a of the electrode can be modified in shape, number and the like, the important aspect of the invention being that the base or surface 18a is modified or roughened in a manner to engage the fetal scalp and increase the resistance to spontaneous unwinding of the spiral from the scalp.

While embodiments of the present invention have been shown and described, various modifications may be made without departing from the scope of the present invention, and all such modifications and equivalents are intended to be covered.
Claims

1. An electrode structure for use in fetal heart monitoring comprising
   a substantially cylindrical electrode body formed of electrically insulating material and having a first end and a second end,
   a spiral electrode extending from the first end of the body and terminating in a pointed end adapted to pierce a fetal epidermal layer,
   a second electrode extending from the electrode body, said second electrode being spaced from and electrically insulated from the spiral electrode, and
   the first end of the electrode body having at least a protrusion underlying a portion of the spiral electrode to increase the resistance of the electrode structure from unwinding from the fetal epidermal layer.

2. An electrode as in Claim 1 with a plurality of said protrusions.

3. An electrode as in Claim 2 wherein said protrusions comprise a pair of points molded as part of the electrode body each having a straight side substantially parallel to a longitudinal axis of the electrode body.

4. An electrode as in Claim 2 wherein said protrusions comprise a plurality of points in the form of substantially forty-five degree triangles extending from the first end and terminating in apexes underlying a part of the spiral electrode.

5. An electrode as in Claim 2 wherein said protrusions comprise a plurality of relatively thin ribs extending from said first surface.
6. An electrode as in Claim 2 wherein each of said protrusions extends to a height from the first end of the electrode body different than that of any other protrusion in the plurality of protrusions.

7. An electrode as in Claim 6 wherein said protrusions extend from the first end to form apexes underlying portions of the spiral electrode, and the apexes are substantially equidistant from the portions of the spiral electrode which they underlie.

8. An electrode structure for use in fetal heart monitoring comprising
   an elongated and substantially cylindrical electrode body formed of electrically insulating material and having a first end and a second end,
   a spiral electrode extending from the first end of the body and terminating in a pointed end adapted to pierce a fetal epidermal layer,
   a second wafer electrode extending from the second end of the electrode body, said, second electrode being electrically insulated from the spiral electrode,
   electrical conductors connected to the respective spiral and wafer electrodes, and
   the first end of the electrode body having a plurality of protrusions underlying a portion of the spiral electrode and arranged substantially equidistant from a portion of the spiral electrode to increase the resistance of the electrode structure from unwinding from the fetal epidermal layer.

9. An electrode as in Claim 8 wherein said protrusions comprise a pair of points molded as part of the electrode body each having a straight side substantially parallel to a longitudinal axis of the electrode body and an inclined side.
10. An electrode as in Claim 9 wherein said protrusions extend from the first end to form apexes underlying portions of the spiral electrode.

11. An electrode as in Claim 8 wherein said protrusions comprise a plurality of points in the form of substantially forty-five degree triangles extending from the first end and terminating in apexes underlying a part of the spiral electrode.

12. An electrode as in Claim 8 wherein said protrusions comprise a plurality of relatively thin ribs extending from said first end surface.

13. The electrode of claim 12 wherein the protrusions are slightly flexible.

14. The electrode of claim 8 wherein the protrusions are straight and not parallel to each other.

15. The electrode of claim 11 wherein the protrusions contact each other.

16. The electrode of claim 8 wherein the protrusions are grouped sufficiently close together to permit gathering of the fetal epidermal layer between them.

17. An electrode comprising a substantially cylindrical electrode body having a first end and a second end, a spiral electrode extending from the first end and having a pointed end, a second electrode extending from the second end of the electrode body, said second electrode electrically insulated from the spiral electrode,
11

electrical conductors connected to the spiral and second electrodes,
a first protrusion on the first end of the electrode body extending radially inwardly from a peripheral cylindrical edge of the electrode body and at least partly underlying the spiral electrode, and
a second protrusion on the first end of the electrode body extending radially inwardly from the peripheral cylindrical edge of the electrode body and at least partly underlying the spiral electrode, the first protrusion having a first height and the second protrusion having a second height, greater than the first height, over the first end of the electrode body, such that the first protrusion and the second protrusion are substantially equally spaced apart from the spiral electrode.

18. The electrode of claim 17 wherein the first protrusion is adjacent the second protrusion.

19. An electrode structure for use in fetal heart monitoring comprising
a substantially cylindrical electrode body formed of electrically insulating material and having a first end and a second end,
a spiral electrode extending from the first end of the body and terminating in a pointed end adapted to pierce a fetal epidermal layer,
a second electrode extending from the electrode body, said second electrode being spaced from and electrically insulated from the spiral electrode, and the first end of the electrode body having at least a protrusion underlying a portion of the spiral electrode to increase the resistance of the electrode structure from unwinding from the fetal epidermal layer.
1. An electrode for use in fetal heart monitoring comprising:
   a substantially cylindrical electrode body formed of electrically insulating material and having a first end
   and a second end,
   a spiral electrode extending from the first end of the body and terminating in a pointed end adapted to pierce a fetal epidermal layer,
   a second electrode extending from the electrode body, said second electrode being spaced apart from and electrically insulated from the spiral electrode, and
   the first end of the electrode having at least a protrusion underlying a portion of the spiral electrode to increase the resistance of the electrode structure from unwinding from the epidermal layer.

2. An electrode as in Claim 1 with a plurality of said protrusions.

3. An electrode as in Claim 2 wherein said protrusions comprise a pair of points molded as part of the electrode body each having a straight side substantially parallel to a longitudinal axis of the electrode body.

4. An electrode as in Claim 2 wherein said protrusions comprise a plurality of points in the form of substantially forty-five degree triangles extending from the first end and terminating in apexes underlying a part of the spiral electrode.

5. An electrode as in Claim 2 wherein said protrusions comprise a plurality of relatively thin ribs extending from said first surface.

6. An electrode as in claim 2 wherein each of said protrusions extends to a height from the first end of the electrode body different than that of any other protrusion in the plurality of protrusions.

7. An electrode as in Claim 2 wherein said protrusions extend from the first end to form apexes underlying portions of the spiral electrode.
8. An electrode as in Claim 7 wherein the apexes are substantially equidistant from the portions of the spiral electrode which they underlie.

9. The electrode of Claim 2 wherein the protrusions are slightly flexible.

10. The electrode of Claim 2 wherein the protrusions are straight and not parallel to each other.

11. The electrode of Claim 2 wherein the protrusions contact each other.

12. The electrode of Claim 2 wherein the protrusions are grouped sufficiently close together to permit gathering of the fetal epidermal layer between them.
