(54) Titre : PROCÉDE DE TRAITEMENT DE DONNEES VIDEO CHIFFREES POUR GENERER DES DONNEES DE PROGRAMME DECHIFFREES

(54) Title: METHOD OF PROCESSING ENCRYPTED VIDEO DATA FOR GENERATING DECRYPTED PROGRAM DATA

(57) Abrégé/Abstract:

A decoder (25) excludes an encryption code or key from decrypted or non-encrypted program output data. Decrypted program representative data is generated (33, 50) from an input datastream containing encrypted program data and an associated encryption code. The encrypted program data is decrypted (130, 33, 50) using the encryption code to provide decrypted program data. An output datastream is formed containing the decrypted program data but excluding the encryption code. The encryption code may be excluded by substituting (110, 55, 60, 115) non-encryption code data for the encryption code. The output datastream may also contain ancillary data formed (115) to support decoding of the decrypted program data.

A decoder (25) excludes an encryption code or key from decrypted or non-encrypted program output data. Decrypted program representative data is generated (33, 50) from an input datastream containing encrypted program data and an associated encryption code. The encrypted program data is decrypted (130, 33, 50) using the encryption code to provide decrypted program data. An output datastream is formed containing the decrypted program data but excluding the encryption code. The encryption code may be excluded by substituting (110, 55, 60, 115) non-encryption code data for the encryption code. The output datastream may also contain ancillary data formed (115) to support decoding of the decrypted program data.

METHOD OF PROCESSING ENCRYPTED VIDEO DATA FOR
GENERATING DECRYPTED PROGRAM DATA

This invention is related to the field of digital signal
5 processing, and more particularly to the conditional access
processing, decoding, and formatting of encrypted packet data for
storage by a consumer receiver of broadcast, satellite or cable
video material, for example.

In video processing and storage applications, digital
10 video data is typically encoded to conform to the requirements of
a known standard. One such widely adopted standard is the
MPEG2 (Moving Pictures Expert Group) image encoding standard,
hereinafter referred to as the "MPEG standard". The MPEG
standard is comprised of a system encoding section (ISO/IEC
15 13818-1, 10th June 1994) and a video encoding section (ISO/IEC
13818-2, 20th January 1995), hereinafter referred to as the
"MPEG systems standard" and "MPEG video standard" respectively.
Video data encoded to the MPEG standard is in the form of a
packetized datastream which typically includes the data content
20 of many program channels (analogous to channels 1-125 in cable
TV, for example). The data content of premium program channels
such as HBO™, Cinemax™ and Showtime™, for example, is usually
protected from unauthorized access by methods such as
encryption and scrambling. These methods may be used alone,
25 repetitively, or in combination to provide a plurality of levels of
protection.

In a decoder, access to the premium channels is
typically governed by a conditional access system which manages
user billing and controls program descrambling and decryption
30 based on user entitlement. The conditional access system may
determine whether access is authorized in a variety of ways. For
example, authorization may be determined within the decoder
from user entitlement information pre-programmed on a so-called
"smart card". Alternatively, authorization may be determined at a
35 remote location and implemented within the decoder using user
entitlement information that is transmitted from the remote
location, as in a cable television pay-per-view service. The

2

entitlement information typically includes codes used to generate descrambling and decryption keys that are used for program descrambling and decryption. However, the entitlement information may instead include the keys themselves.

5 The processing of encrypted and non-encrypted program data and the management of associated encryption and scrambling codes for storage, billing and other applications presents a number of problems. One problem is presented by the need to maintain encryption code security when a program is
10 stored by a consumer in either encrypted or non-encrypted form for viewing at a later time. Further problems are involved in providing a system that permits billing on the storage or playback of a program and that permits copy protected processing of encrypted and non-encrypted program data.

15 These problems are addressed by a system according to the present invention. Hereinafter the term "encryption" encompasses scrambling functions to the extent that the functions are used to prevent unauthorized use.

 In a decoder system that processes encrypted program
20 data to provide decrypted program data for output, a compromise in encryption key security occurs if encryption keys are exported from the decoder. In particular, security is compromised if encryption keys, or encryption codes from which keys are derived, become accessible by third parties. This may occur, for
25 example, if encryption keys are output from a decoder and are stored on removable storage media or otherwise become externally accessible. Once keys are externally accessible e.g. on a storage media, their security is dependent on the sophistication of available reverse engineering and code-breaking techniques. The
30 inventors have recognized that it is desirable to provide a decoder capable of inhibiting the output of an encryption code or key.

 In accordance with the principles of the present invention, a decoder excludes an encryption code or key from decrypted or non-encrypted program output data. A method for
35 generating decrypted program representative data from an input datastream containing encrypted program data and an associated encryption code involves decrypting the encrypted program data.

WO 98/24236

PCT/US97/19374

3

The encrypted program data is decrypted using the encryption code to provide decrypted program data. An output datastream is formed containing the decrypted program data but excluding the encryption code.

5 In a feature of the invention, the encryption code is excluded from ancillary data formed to support decoding of the decrypted program data and contained in the output datastream.

In another feature of the invention, non-encryption code data is substituted for the encryption code in the output
10 datastream.

Brief Description of the Drawings

In the drawing:

15 Figure 1 shows a video receiver system, according to the invention, for adaptively generating a program representative datastream in user selectable, encrypted or non-encrypted form.

Figures 2 and 3 show a process flowchart for providing
20 a program representative datastream suitable for storage on a selectable storage medium and for executing the associated user billing.

Figure 4 shows a flowchart for a process for recovering
25 selected encrypted or non-encrypted programs from a selected storage device and for billing a user upon program recovery.

Figure 1 shows a video receiver system, according to the invention, for adaptively generating a program representative datastream, in user selectable, encrypted or non-encrypted form.
30 Although the disclosed system is described in the context of an MPEG compatible system for receiving MPEG encoded transport streams representing broadcast programs, it is exemplary only. The principles of the invention may also be applied to other types of system including non-MPEG compatible systems, involving
35 other types of encoded datastreams. Further, although the disclosed system is described as processing broadcast programs, this is exemplary only. The term 'program' is used to represent

any form of packetized data such as telephone messages, computer programs, Internet data or other communications, for example.

In overview, in the video receiver system of Figure 1, a carrier modulated with video data is received by antenna 10 and processed by unit 15. The resultant digital output signal is demodulated by demodulator 20 and decoded by decoder 30. The output from decoder 30 is processed by transport system 25 which is responsive to commands from remote control unit 125. System 25 provides compressed data outputs for storage, further decoding, or communication to other devices. System 25 incorporates a conditional access system for managing user billing and for controlling program descrambling and decryption based on user entitlement. A video receiver user selects the program he wishes to view, the programs he wishes to store, the type of storage media used and whether the programs are to be stored in encrypted or non-encrypted form by on-screen menu selection using remote control unit 125. System 25 also provides a mechanism for permitting real time or non-real time removal of encryption codes from a non-encrypted program datastream.

Video and audio decoders 85 and 80 respectively, decode the compressed data from system 25 to provide outputs for display. Data port 75 provides an interface for communication of the compressed data from system 25 to other devices such as a computer or High Definition Television (HDTV) receiver, for example. Storage device 90 stores the compressed data from system 25 on storage medium 105. Device 90, in a playback mode, also supports retrieval of the compressed data from storage medium 105 for processing by system 25 for decoding, communication to other devices or storage on a different storage medium (not shown to simplify drawing). The conditional access system within system 25 supports the decryption and billing for program storage, playback, or further processing including communication to other devices. The conditional access system of system 25 employs a different decryption and billing mechanism for processing program data received from a broadcast source than from data played back from a local storage source.

5

Considering Figure 1 in detail, a carrier modulated with video data received by antenna 10, is converted to digital form and processed by input processor 15. Processor 15 includes radio frequency (RF) tuner and intermediate frequency (IF) mixer and amplification stages for down-converting the input video signal to a lower frequency band suitable for further processing. The resultant digital output signal is demodulated by demodulator 20 and decoded by decoder 30. The output from decoder 30 is further processed by transport system 25.

10 Multiplexer (mux) 37 of service detector 33 is provided, via selector 35, with either the output from decoder 30, or the decoder 30 output further processed by NRSS (National Renewable Standards Committee) descrambling unit 40. Selector 35 detects the presence of an insertable, NRSS compatible, 15 descrambling card and provides the output of unit 40 to mux 37 only if the card is currently inserted in the video receiver unit (the NRSS removable conditional access system is defined in EIA Draft Document IS-679, Project PN-3639). Otherwise selector 35 provides the output from decoder 30 to mux 37. The presence of 20 the insertable card permits unit 40 to descramble additional premium program channels, for example, and provide additional program services to a viewer. It should be noted that NRSS unit 40 and smart card unit 130 (smart card unit 130 is discussed later) share the same system 25 interface such that only either an 25 NRSS card or a smart card may be inserted at any one time. Alternatively, the interfaces may be separate to allow series or parallel operation.

The data provided to mux 37 from selector 35 is in the form of an MPEG compliant packetized transport datastream as 30 defined in MPEG systems standard section 2.4 and includes the data content of one or more program channels. The individual packets that comprise particular program channels are identified by Packet Identifiers (PIDs). The transport stream contains ancillary data supporting transmission and decoding of transport 35 encoded data. The ancillary data includes Program Specific Information (PSI) for use in identifying the PIDs and assembling individual data packets to recover the content of all the program

WO 98/24236

PCT/US97/19374

6

channels that comprise the packetized datastream. A video receiver user selects the program he wishes to view, the programs he wishes to store, the media to be used for storage and whether the programs are to be stored in encrypted or non-encrypted form by on-screen menu selection using remote control unit 125. System controller 115 uses the selection information, provided via interface 120, to configure system 25 to select the programs for storage and display and to generate PSI suitable for the selected storage device and media. Controller 115 configures system 25 elements 45, 47, 50, 55, 65 and 95 by setting control register values within these elements via a data bus and by selecting signal paths via muxes 37 and 110 with control signal C. Controller 115 is also programmable to permit real time and non-real time removal of encryption codes from a non-encrypted program datastream that is to be stored or otherwise processed. This feature enhances encryption security by preventing the export of encryption keys beyond system 25 thereby limiting availability to third parties.

In response to control signal C, mux 37 selects either the transport stream from unit 35, or in a playback mode, a datastream retrieved from storage device 90 via store interface 95. In normal, non-playback operation, the data packets comprising the program that the user selected to view are identified by their PIDs by selection unit 45. If an encryption indicator in the header data of the selected program packets indicates the packets are encrypted, unit 45 provides the packets to decryption unit 50. Otherwise unit 45 provides non-encrypted packets to transport decoder 55. Similarly, the data packets comprising the programs that the user selected for storage are identified by their PIDs by selection unit 47. Unit 47 provides encrypted packets to decryption unit 50 or non-encrypted packets to mux 110 based on the packet header encryption indicator information.

Units 45 and 47 employ PID detection filters that match the PIDs of incoming packets provided by mux 37 with PID values pre-loaded in control registers within units 45 and 47 by controller 115. The pre-loaded PIDs are used in units 47 and 45 to

identify the data packets that are to be stored and the data packets that are to be decoded for use in providing a video image. The pre-loaded PIDs are stored in look-up tables in units 45 and 47. The PID look-up tables are memory mapped to encryption key tables in units 45 and 47 that associate encryption keys with each pre-loaded PID. The memory mapped PID and encryption key look-up tables permit units 45 and 47 to match encrypted packets containing a pre-loaded PID with associated encryption keys that permit their decryption. Non-encrypted packets do not have associated encryption keys. Units 45 and 47 provide both identified packets and their associated encryption keys to decryptor 50. The PID look-up table in unit 45 is also memory mapped to a destination table that matches packets containing pre-loaded PIDs with corresponding destination buffer locations in packet buffer 60. The encryption keys and destination buffer location addresses associated with the programs selected by a user for viewing or storage are pre-loaded into units 45 and 47 along with the assigned PIDs by controller 115.

The encryption keys are generated by ISO 7816-3 compliant smart card system 130 from encryption codes extracted from the input datastream. The generation of the encryption keys is subject to customer entitlement determined from coded information pre-stored on the insertable smart card itself (International Standards Organization document ISO 7816-3 of 1989 defines the interface and signal structures for a smart card system). Customer entitlement information may be periodically changed by updating the coded information on the insertable smart card via commands in the input datastream.

The insertable, ISO 7816-3 compliant smart card advantageously contains three algorithm functions. Two of the algorithm functions, termed the broadcast encryption algorithms, are assigned to generate encryption keys from broadcast encryption codes extracted from the input datastream in non-playback modes of system 25. A broadcast encryption algorithm generates encryption keys by decrypting broadcast encryption codes within smart card 130 itself. The third algorithm function is applied in system 25 for encrypting and decrypting the derived

broadcast encryption keys in storage and playback modes of system 25. The playback algorithm encrypts and decrypts the broadcast encryption keys within the insertable smart card itself. However, in other systems, the playback algorithm function may
5 reside elsewhere, such as in a decoder, for example.

The three encryption algorithms used in smart card
130 may be any one of a variety of types and the playback algorithm need not be the same type as the broadcast algorithm. For exemplary purposes, the broadcast and playback algorithms
10 are deemed to be Data Encryption Standard (DES) algorithm functions as defined in Federal Information Standards (FIPS) Publications 46, 74 and 81 provided by the National Technical Information Service, Department of Commerce. However, these
algorithm functions may alternatively be another type such as
15 Rivest-Shamir-Adleman (RSA) type functions.

Each of the two broadcast encryption algorithms that are resident on the smart card may be activated by control information in the input datastream. Two broadcast encryption algorithms are contained within the smart card in order to permit
20 a service provider to make a simultaneous change in broadcast encryption algorithm for all customers. A service provider makes a change in broadcast encryption algorithm by issuing a new smart card with a new algorithm to all customers safely in advance of the date the new algorithm is to be employed. On the
25 change date, the service provider simultaneously: commands the smart card to change to the new algorithm by updating the control information in the broadcast datastream; encrypts programs with the new algorithm; and inserts updated encryption codes in the broadcast datastream. A change in algorithm may be implemented
30 by a service provider on a regular basis or as frequently as desired in order to safeguard encryption system security and prevent code-breaking and unauthorized program access.

The inventors have recognized that the use of such an encryption system involving changing encryption keys poses a
35 problem for storage of programs in encrypted form. Specifically, a program stored in encrypted form along with an associated broadcast encryption code may not be able to be decrypted once

the smart card has been changed and the smart card algorithms have been updated. This is because the new algorithm on the smart card is not compatible with an encryption code associated with an earlier version smart card. Consequently, the new smart card algorithm is unable to derive the required broadcast encryption key from the stored encryption code. This means that the stored encrypted program cannot be decrypted and is unusable once a system smart card has been changed.

In order to overcome this problem, a third and different algorithm, the playback algorithm, is advantageously incorporated on the smart card. The third algorithm function, termed the playback algorithm, is used in specific operations and modes of system 25 for encrypting broadcast encryption keys to form playback encryption codes in storage and playback modes of system 25.

Once encrypted by the playback algorithm, the playback encryption codes may be securely stored, along with encrypted program content, on a storage medium. Upon playback of the encrypted program, the playback algorithm function decrypts the stored encryption codes to derive the original broadcast encryption keys to enable decryption of the encrypted program content. The derived broadcast encryption keys are used by unit 50 to decrypt encrypted program content packets as described later. The playback algorithm is not changed as frequently as the two broadcast algorithms and may be left unchanged in successive versions of smart card. This enables the stored encrypted program to be decrypted and used despite changes in smart cards and broadcast encryption algorithms.

The packets provided by units 45 and 47 to unit 50 are encrypted according to the Data Encryption Standard (DES). Decryption unit 50 of system 25 of Figure 1 employs the DES algorithm function in decrypting these encrypted packets. In other implementations of system 25 unit 50 may alternatively use other algorithm functions such as the previously mentioned RSA function. Unit 50 applies known techniques to decrypt the encrypted packets using corresponding encryption keys provided by smart card 130 via units 45 and 47. The decrypted packets

10

from unit 50 and the non-encrypted packets from unit 45 that comprise the program for display are provided to decoder 55. The decrypted packets from unit 50 and the non-encrypted packets from unit 47 that comprise the program for storage are provided 5 to mux 110.

Unit 60 contains packet buffers accessible by controller 115. One of the buffers is assigned to hold data destined for use by controller 115 and three other buffers are assigned to hold packets that are destined for use by application devices 75, 10 80 and 85. A further buffer, the substitution buffer discussed later, is used to hold data for substituting for encryption code data. Access to the packets stored in the buffers within unit 60 by both controller 115 and by application interface 70 is controlled by buffer control unit 65. Unit 45 provides a destination flag to 15 unit 65 for each packet identified by unit 45 for decoding. The flags indicate the individual unit 60 destination locations for the identified packets and are stored by control unit 65 in an internal memory table. Control unit 65 determines a series of read and write pointers associated with packets stored in buffer 60 based 20 on the First-In-First-Out (FIFO) principle. The write pointers in conjunction with the destination flags permit sequential storage of an identified packet from units 45 or 50 in the next empty location within the appropriate destination buffer in unit 60. The read pointers permit sequential reading of packets from the 25 appropriate unit 60 destination buffers by controller 115 and application interface 70.

The non-encrypted and decrypted packets provided by units 45 and 50 to decoder 55 contain a transport header as defined by section 2.4.3.2 of the MPEG systems standard. Decoder 30 55 determines from the transport header whether the non-encrypted and decrypted packets contain an adaptation field (per the MPEG systems standard). The adaptation field contains timing information including, for example, Program Clock References (PCRs) that permit synchronization and decoding of content 35 packets. Upon detection of a timing information packet, i.e., a packet containing an adaptation field, decoder 55 signals controller 115 that the packet has been received, by setting a

11

system interrupt within an interrupt mechanism. In addition, decoder 55 changes the timing packet destination flag in unit 65 and provides the packet to unit 60. By changing the unit 65 destination flag, unit 65 diverts the timing information packet 5 provided by decoder 55 to the unit 60 buffer location assigned to hold data for use by controller 115, instead of to an application buffer location.

Upon receiving the system interrupt set by decoder 55, controller 115 reads the timing information and PCR value and 10 stores it in internal memory. PCR values of successive timing information packets are used by controller 115 to adjust the system 25 master clock (27 MHz). The difference between PCR based and master clock based estimates of the time interval between the receipt of successive timing packets, generated by 15 controller 115, is used to adjust the system 25 master clock (not shown to simplify drawing). Controller 115 achieves this by applying the derived time estimate difference to adjust the input control voltage of a voltage controlled oscillator used to generate the master clock. Controller 115 resets the system interrupt after 20 storing the timing information in internal memory.

Packets received by decoder 55 from units 45 and 50 that contain program content including audio, video, caption, and other information, are directed by unit 65 from decoder 55 to the designated application device buffers in packet buffer 60. 25 Application control unit 70 sequentially retrieves the audio, video, caption and other data from the designated buffers in buffer 60 and provides the data to corresponding application devices 75, 80 and 85. The application devices comprise audio and video decoders 80 and 85 and high speed data port 75. Data port 75 30 may be used to provide high speed data such as computer programs, for example to a computer. Alternatively port 75 may be used to output data to an HDTV decoder, for example.

Packets that contain PSI information are recognized by unit 45 as destined for the controller 115 buffer in unit 60. 35 The PSI packets are directed to this buffer by unit 65 via units 45, 50 and 55 in a similar manner to that described for packets

containing program content. Controller 115 reads the PSI from unit 60 and stores it in internal memory.

Controller 115 employs the process of Figures 2 and 3 to generate a program datastream suitable for storage on medium 5 105 and to bill a user for the storage. Controller 115 also employs the process of Figures 2 and 3 both to generate a playback encryption code for storage on medium 105, and to remove the original broadcast encryption codes from the program datastream to be stored. The packet identification and direction process of 10 Figures 2 and 3 is governed by controller 115, control unit 65, and the PID, destination and encryption key look-up tables of units 45 and 47 in the manner previously described.

The CPSI (Condensed Program Specific Information) contains information related to the particular program to be 15 stored, whereas the PSI contains information related to all the programs in the datastream input to system 25. Consequently, the CPSI takes up less storage capacity and imposes less overhead than the PSI. In addition, given a fixed overhead constraint, the CPSI may be repeated in a datastream more frequently than the 20 PSI and so may be derived and applied to reduce the recovery latency of program content.

The PSI as defined in MPEG systems standard section 2.4.4 comprises four non-encrypted elements or tables of information. These are the Program Association Table (PAT), the 25 Program Map Table (PMT), the Network Information Table (NIT) and the Conditional Access Table (CAT). Each table is formed from data packets that are recognized by a particular PID. The PMT defines the PID labels that identify the individual packetized datastreams that constitute a program. These individual streams 30 are termed elementary streams in the MPEG standard. Elementary streams include datastreams such as video, audio for various languages and caption datastreams. The PAT associates a program number with the PIDs that permit identification and assembly of the packets comprising the PMT. The NIT is optional and may be 35 structured and used to define physical network parameters such as satellite transmission channel frequencies and transponder channels, for example. The CAT contains the conditional access

13

information such as encryption codes that govern access to programs that are dependent upon user entitlement.

In step 205 of Figure 2, controller 115 (Figure 1) performs an initialization procedure at system power-up following the start at step 200. In step 205, controller 115 loads the unit 45 (Figure 1) PID detection filters with the MPEG defined PID values for the PAT and CAT tables (PIDs hex value 0000 and hex value 0001 respectively). In addition, controller 115 pre-assigns the PAT and CAT packets to the controller buffer in unit 60 by updating the unit 45 destination table. The PAT and CAT packets detected by unit 45 are steered via decoder 55 to the controller buffer in unit 60 under control of unit 65. In step 205, control unit 65 signals controller 115 via a PSI interrupt that PSI packets are present in unit 60. Controller 115, upon receipt of the PSI interrupt, repetitively accesses the packets stored in its designated unit 60 buffer and stores the complete CAT and PAT data in internal memory. Controller 115 repeats this process to store complete PMT and NIT data in internal memory after determining the PIDs that identify the PMT and NIT packets from the PAT. Controller 115 continuously accesses buffer 60 and captures PSI packets in internal memory upon receipt of PSI interrupts while the receiver is powered on. As a result, controller 115 captures in its internal memory the PAT, PMT, NIT and CAT data that comprises the full PSI of the transport datastream input to system 25.

In step 210 of Figure 2, user generated data (SP, SM, SE) identifying the programs a user wishes to store, as well as those programs that are to be stored in encrypted form, and the media and device to be used for storage, is input to controller 115 (Figure 1). A user may select encrypted storage in preference to non-encrypted storage for a variety of reasons. For example, a service provider may make it cheaper to store in encrypted form as a way of limiting the number of subsequent copies a user may make. A service provider may achieve this by controlling access to the encrypted program via pre-stored smart card entitlement information. The selection data input to controller 115 is entered by a user through on-screen menu selection with

14

remote control unit 125 via interface 120. In step 215, in response to the input selection data (SP), controller 115 derives the PIDs for the selected programs for storage from the stored PSI. The unit 47 detection filters are loaded with the PIDs of the programs to be stored by controller 115. This enables unit 47 to identify the packets comprising the programs selected for storage. In step 215, controller 115 also pre-loads the unit 60 substitution buffer with null data. The null data is to be substituted for broadcast encryption codes occurring in programs broadcast in encrypted form that are selected for storage.

In step 215 of Figure 2, unit 47 (Figure 1) provides non-encrypted packets to mux 110 and provides encrypted packets (identified by an encryption indicator in the packet header data) along with associated broadcast encryption keys to decryption unit 50. The broadcast encryption keys are provided to unit 47 by controller 115 in step 215 of Figure 2, following their generation by smart card 130 (Figure 1) by decryption of encryption codes obtained from the CAT for the selected programs (SP) in the manner previously described. However, if selection data SE requests encrypted storage, unit 47 passes the encrypted packets to be stored to mux 110. Consequently, in step 215 of Figure 2, the packets comprising the programs to be stored (SP) are provided to mux 110 either in encrypted or decrypted form in response to selection data SE.

In steps 217-227, controller 115 forms condensed program specific information (CPSI) for the programs selected for storage (SP) from the full program specific information (PSI) captured from the transport datastream input to system 25. If the SE data requests encrypted storage, controller 115 performs step 227 following decision step 217. In step 227, controller 115 applies the playback algorithm function in smart card system 130 to encrypt the broadcast encryption key previously generated (by decryption of a broadcast encryption code) in step 215 to form a playback encryption code for the program to be stored. The CPSI is formed to include the playback encryption code but to exclude the broadcast encryption code originally present in the PSI of the transport datastream input to system 25. Consequently, the

15

datastream formed for the program destined for storage excludes its associated broadcast encryption code. This prevents the compromise in encryption key security that occurs when encryption keys are stored on removable storage media accessible
5 by third parties. Once keys are accessible on a storage media, their security is dependent on the sophistication of available reverse engineering and code-breaking techniques. In this system, multiple levels of security are provided by not storing the broadcast encryption codes from which the broadcast encryption
10 keys are derived and by storing the broadcast encryption keys in encrypted form. Further, even if the keys were deduced for the stored program, it would not provide access to current broadcast programs for which the broadcast encryption algorithm is regularly changed.

15 If the SE input data does not request encrypted storage, controller 115 performs step 225 following decision step 217. In step 225, controller 115 forms the CPSI of the program destined for storage from the PSI of the transport datastream input to system 25 and excludes encryption codes from the CPSI.

20 The described encryption system is exemplary only. Alternative encryption mechanisms may convey the broadcast and playback encryption codes in datastream information areas other than the PSI. Other encryption mechanisms may also require the generation and insertion of the encryption codes at
25 different intervals than is involved in the generation of the PSI. If broadcast encryption codes are not conveyed in PSI, substitution of other data for the these codes may be necessary to exclude them from the datastream formed for the program to be stored. Provision for substitution of null data for the broadcast encryption
30 codes at intervals other than those at which the CPSI occurs is discussed later. Specifically, substitution of broadcast encryption codes in real-time i.e. at packet frequency when the codes are conveyed in packet headers, for example, is discussed in connection with steps 237 - 249.

35 In step 230, controller 115 forms the CPSI data into sections in accordance with the MPEG syntax (paragraphs 2.4.4.3 - 2.4.4.11 of the MPEG systems standard). Controller 115, in step

16

230, also adds header data to the CPSI data sections to format and packetize the CPSI data for insertion into the datastream to be stored. Controller 115 creates the headers in accordance with sections 2.4.3.2 and 2.4.3.3 of the MPEG systems standard from the PSI header data stored in the controller 115 internal memory. However, CPSI section data is different in length relative to corresponding PSI section data. Therefore, new header parameters including the 'continuity count' indicator and 'payload unit start indicator' are created by controller 115 and inserted in the respective indicator fields within the header data. The new continuity count indicator created by controller 115 reflects, for example, the number of packets per PID for the CPSI elements instead of the different number of packets per PID of the corresponding PSI elements. The new payload unit start indicator created by controller 115 identifies, for example, the first byte of the CPSI section instead of the first byte of the corresponding PSI section.

Following step 230, the flowchart of Figure 2 continues with step 237 of Figure 3. Controller 115 determines, in step 237, whether broadcast encryption codes are conveyed in datastream fields other than the CPSI. Specifically, controller 115 determines whether broadcast encryption codes are conveyed in MPEG compatible adaptation fields of packet headers (per MPEG systems standard syntax section 2.4.3.4). If so, controller 115 performs step 249 to create a composite datastream that comprises CPSI packets and program content packets with null data substituted for the broadcast encryption codes in the packet headers. The encryption code substitution is performed on a packet by packet basis at packet frequency.

In step 249, the substitution packet data pre-loaded during step 215 (Figure 2) into the substitution buffer in unit 60 is provided from unit 60 to mux 110 (Figure 1) under control of controller 115. In addition, in step 249, the CPSI in the form of packetized MPEG compatible section data formed in step 230 is provided by controller 115 to mux 110 (Figure 1). Program content packet datastreams from unit 47 or unit 50 as previously discussed in connection with step 215, are also provided to mux

110. In step 249, controller 115 multiplexes between the program content datastream, the CPSI datastream, and the substitution data input to mux 110 using path select signal C to create a composite datastream that is output by mux 110 to storage interface 95. The composite datastream comprises program content packets and CPSI packets with null data substituted for the broadcast encryption codes in the packet headers.

Controller 115 synchronizes insertion of the CPSI packets and null data into the program datastream to be stored, in response to a PSI interrupt signal and a substitution timing signal from control unit 65 (Figure 1). The PSI interrupt indicates the presence of PSI packets in buffer 60 as discussed in connection with step 205. The substitution timing signal synchronizes insertion of null data with the occurrence of the broadcast encryption codes in packet headers. In this manner, the packetized sections of the CPSI are inserted into PSI locations to replace the corresponding sections of the PSI and the broadcast encryption codes are removed. The non-encrypted CPSI data is insertable in either the encrypted or non-encrypted program content datastreams that are input to mux 110 in order to create either encrypted or non-encrypted programs for storage.

It should be noted that the broadcast encryption code substitution performed in step 249 may also be applied to codes conveyed in datastream fields other than the MPEG packet header adaptation fields. Further, the encryption codes may be replaced at intervals other than those at which the adaptation fields occur. For example, null data may be substituted for encryption codes occurring in a variety of MPEG and non-MPEG compatible datastream locations including: auxiliary packets within the proprietary Digital Satellite System (DSS™); Packetized Elementary Stream (PES) fields (per MPEG systems standard syntax sections 2.5.3.7 - 2.5.4.2); Digital Storage Media Control Commands (DSMCC) fields (per MPEG systems standard syntax Appendix A); and non-MPEG packets formatted according to other data transmission protocols such as the standardized CEBus control protocol (Home Automation Standard (CEBus), EIA/IS-60, December 1989).

18

If the encryption codes are conveyed in packets in which the codes themselves are the only data items of consequence, the code carrying packets may be omitted entirely from the output datastream. This may be accomplished by discarding the packets via PID selection units 45 and 47 (Figure 1) or by omitting the packets during the multiplexing operation performed in step 249. However, data rate and data structure sensitive parameters within the output datastream syntax may need to be updated to reflect the data rate change occurring as a result of such packet data omission.

In step 249, store interface 95 (Figure 1) receives the programs to be stored in the form of the packetized datastream (hereinafter termed the CPSI stream) incorporating the CPSI and null data from mux 110. In step 254 (Figure 3), following step 249, the conditional access system within system 25 bills the User for the program storage (or communication to other devices). The User is billed by storing billing information within the insertable smart card itself. The storage of the billing information is initiated by the application of the playback algorithm but billing need not be contemporaneous with application of the algorithm. The billing information indicates that the User has stored an encrypted broadcast program. This billing information is later accessed via telephone link by the service provider and used to bill the User via a conventional billing process. Other billing mechanisms are equally possible. For example, credits may be deducted from a pre-stored credit sum within a smart card. Further, the smart card may vary billing amount based on the type of storage requested e.g. there may be one fee for storage permitting only a single copy or playback of the stored program and another fee for storage permitting unlimited copying or playback of the program. The type of storage requested is encoded within designated copy protection data in the CPSI stream itself or in packet data external to the CPSI stream. The process of Figures 2-3 used by controller 115 to generate a program datastream (the CPSI stream) suitable for storage on medium 105 and to bill a user for the storage terminates at step 258.

If controller 115 determines, in step 237, that no broadcast encryption codes are conveyed in MPEG compatible adaptation fields of packet headers, controller 115 performs steps 240 - 245. These steps mirror steps 249-258 except that because there are no broadcast encryption codes present in the datastreams input to mux 110 representing the program to be stored, there is no need for insertion of null data. Otherwise, controller 115 performs step 240 to create the CPSI stream for storage via store interface 95 and performs step 244 to bill the user for storage in similar fashion to that described in connection with steps 249 and 254. This branch of the process of Figures 2-3 terminates at step 245. However, it should be noted that the CPSI stream may alternatively be provided to other applications in steps 240 and 249 such as display or communication via interface 70 instead of storage via interface 95.

The CPSI stream from mux 110 is buffered by interface 95 to reduce gaps and bit rate variation in the data. The resultant buffered data is processed by storage device 90 to be suitable for storage on medium 105. Controller 115 initiates and controls the operation of storage device 90 (Figure 1) by command via I/O port 100 using a standardized CEBus control protocol (e.g. Home Automation Standard (CEBus), EIA/IS-60, December 1989). Storage device 90 is a linear storage medium DVHS™ type device and medium 105 is a linear sequential access type medium such as video tape, for example. Storage device 90 encodes the buffered datastream from interface 95 using known error encoding techniques such as channel coding, interleaving and Reed Solomon encoding to produce an encoded datastream suitable for storage. Unit 90 stores the resultant encoded datastream incorporating the CPSI on tape medium 105.

Although described as a DVHS™ device that stores data on a linear type storage medium in the exemplary embodiment of Figure 1, storage unit 90 may be any type of storage unit. For example, unit 90 may be a solid state or nonlinear type device for storing data in RAM or on a nonlinear medium. A nonlinear type medium is a medium that accommodates non-sequential access such as a disc medium including CDROM or DVD, for example. If

20

unit 90 and medium 105 are nonlinear or solid state type storage systems, unit 90 separates the CPSI data from the CPSI stream and stores the CPSI data in a designated directory section of the medium. This advantageously avoids repeated storage of the CPSI
5 and reduces the required storage capacity. Alternatively, unit 90 may store the CPSI stream as formed and input to unit 90, incorporating one or more repetitions of the CPSI data.

Further, system 25 of Figure 1 may incorporate a plurality of storage/retrieval paths that support the operation of a
10 plurality of storage devices of various types including linear, nonlinear and solid state types. The single storage/retrieval path shown in Figure 1 comprises units 47, 90, 95, 105 and 110, as described. By replicating these elements to create parallel storage functions, system 25 is readily extended to incorporate a plurality
15 of storage paths. The storage path and programs destined for a particular storage device are selected by user generated data (SP, SM) input to controller 115 via interface 120 following on-screen menu selection with remote control unit 125, as previously described.

20 System 25 of Figure 1 recovers programs from storage device 90 and medium 105 in a playback mode using the process of Figure 4. The recovered datastreams are processed by system 25 and provided to application devices 75, 80 and 85 for display or output, for example. Alternatively, the program datastreams
25 may be stored on other parallel storage devices (not shown in Figure 1 to simplify the drawing).

In step 505 of Figure 4, following the start at step 500, user generated data (SR, SM) is input to controller 115 of system 25 (Figure 1) identifying the programs (SR) to be recovered and
30 the storage device (SM) from which the programs are to be recovered. The user selection data is input to controller 115 via interface 120 following on-screen menu selection with remote control unit 125. It is assumed for exemplary purposes that the user selects programs to be recovered from storage device 90
35 (Figure 1).

Controller 115, in step 510, initiates recovery of the selected program datastreams by device 90 from medium 105 by

21

command via I/O port 100 using the standardized CEBus control protocol as previously discussed. Device 90 decodes the error encoded data retrieved from medium 105 to recover the corresponding data originally provided to device 90 for storage. 5 Device 90 may be a DVHS™ linear type storage unit or another type of storage unit such as a solid state RAM or nonlinear type DVD or CDROM type device. The recovered decoded datastreams are transferred, in step 510, by device 90 to interface 95. This data transfer is controlled and synchronized by controller 115 via 10 the standard CEBus. Interface 95, buffers the data received from unit 90 to adjust the time intervals between data packets to provide a buffered data output that is MPEG compatible and complies with MPEG bit rate constraints.

In step 515, controller 115 directs the buffered output 15 from interface 95 (the playback datastream) via mux 37 to PID selection units 45 and 47 using path select signal C. In step 515, controller 115 determines whether single copy or unlimited copy limitations that were encoded in the designated copy protection data in steps 244 and 254 (Figure 3), are being exceeded by the 20 recovered program. Subject to recovery being permitted, controller 115, in step 515 (Figure 4), recovers the playback encryption code that was generated in step 227 (Figure 2) from the CAT for the selected programs (SR) and provides the code to smart card unit 130 in the manner previously described in 25 connection with step 215 (Figure 2). Under control of controller 115, smart card 130, in step 515 (Figure 4), applies the playback algorithm to generate the original broadcast encryption keys from the playback encryption code. The broadcast encryption keys are provided to the PID, destination and encryption key look-up 30 tables in units 45 and 47 by controller 115 in step 515.

In step 520, units 45 and 47 and the remaining units of system 25 process the playback datastream either for storage via mux 110 or for application use via interface 70. Both the playback datastream from unit 95 and the transmitted 35 datastream from selector 35, following selection via mux 37, are processed by system 25 in a similar manner. Both these datastreams are processed in the way previously described for

22

the transmitted datastream except for the encryption key generation steps and for the CPSI processing steps. In playback mode, smart card 130 applies a playback encryption key generation algorithm instead of a broadcast key generation
5 algorithm. Smart card unit 130 applies the playback algorithm function to decrypt the encryption codes previously encoded with the playback encoding algorithm in step 227 of Figure 2. Thereby, unit 130 derives the original broadcast encryption keys for the program selected for playback (SR). The broadcast encryption
10 keys are used by DES decryption unit 50 to decrypt the encrypted program content packets in subsequent step 520 (Figure 4) in the manner previously described for the transmitted datastream. However, the playback datastream selected via mux 37 already incorporates the CPSI. Therefore, in the playback mode, controller
15 115 in step 520, does not perform the steps related to CPSI formation described in connection with Figures 2-3.

In the exemplary playback mode shown in Figure 4, system 25 in step 520, transport decodes the playback datastream to provide decoded data to application decoders 80 and 85, for
20 display. In this mode, system 25 applies the latest complete CPSI data contained in the playback datastream, in accordance with the MPEG standard, to provide a transport decoded datastream representing selected program SR.

The CPSI is applied in transport decoding the playback
25 datastream using PID filters 45 and 47, decryptor 50, decoder 55, buffer 60 and control unit 65 in a manner similar to that previously described in connection with Figure 1. The transport decoded datastream, excluding the CPSI, is provided, via interface 70, to application decoders 80 and 85 for MPEG decoding and
30 image reproduction. In other modes, system 25 provides the playback datastream incorporating the CPSI to other application devices such as to high speed data port 75, for example. The CPSI is then available to be applied in transport decoding the playback datastream, as necessary, by these application devices or
35 subsequent devices. If the playback datastream is to be stored to a second storage device other than device 90, for example, mux 110 provides the datastream, incorporating the CPSI, to the

23

second storage device via a second storage interface. Further, the second storage device and interface (neither are shown in Figure 1) mimic the operation and function of units 90 and 95 respectively. The data from interface 70, MPEG decoded by application decoders 80 and 85, is presented via audio and image reproduction devices in units 80 and 85 respectively.

In step 527 (Figure 4), the conditional access system within system 25 bills the User for the program playback. The User is billed within the insertable smart card itself by storage of billing information upon the application of the playback algorithm. The billing information indicates that the User has recovered an encrypted broadcast program. This billing information is later accessed via telephone link by the service provider and used to bill the User via a conventional billing process. Other billing mechanisms, as previously described, may equally be used. The playback process of Figure 4 terminates at step 530.

The architecture of Figure 1 is not exclusive. Other architectures may be derived in accordance with the principles of the invention to accomplish the same objectives. Further, the functions of the elements of the Figure 1 architecture and the process steps of Figure 2-4 may be implemented in whole or in part within the programmed instructions of a microprocessor. In addition, the principles of the invention apply to any system using an MPEG or non-MPEG compatible electronic program guide for conveying any of the information described herein as being conveyed in MPEG PSI tables. The invention principles are not restricted to program guides or PSI conveyed in MPEG compatible PSI tables.

What is claimed is:

1. In a video decoder for receiving and processing digital video data for output and subsequent remote or local storage, a method for processing program representative data from an input datastream containing a broadcast encrypted encryption key and associated broadcast encrypted program data, comprising the steps of:

decrypting said broadcast encrypted encryption key received in said input datastream using a first algorithm to provide a broadcast encryption key for use in decrypting said broadcast encrypted program data;

re-encrypting said broadcast encryption key using a second algorithm to provide an encrypted playback key for use in decrypting encrypted program data recovered from a storage medium; and

formatting said encrypted playback key together with said associated broadcast encrypted program data to form output data suitable for storage on a storage medium by

excluding said broadcast encrypted encryption key from said output data
and

incorporating said encrypted playback key in said output data.

2. A method according to claim 1, wherein said formatting step includes the step of

substituting null data for said broadcast encrypted encryption key.

3. A method according to claim 1, wherein said formatting step includes the step of

incorporating data structure parameters in said output data to be compatible with the data structure resulting from excluding said broadcast encrypted encryption key and incorporating said encrypted playback key.

4. In a video decoder for receiving and processing digital video data for output and subsequent remote or local storage, method for adaptively processing

program representative data from an input datastream containing a broadcast encrypted encryption key and associated broadcast encrypted program data, comprising the steps of:

receiving user generated data for selecting one of (a) a decrypted program output mode and (b) an encrypted program output mode;

decrypting said broadcast encrypted encryption key received in said input datastream using a first algorithm to provide a broadcast encryption key for use in decrypting said broadcast encrypted program data:

in a decrypted program output mode,

decrypting said broadcast encrypted program data using said broadcast encryption key to provide decrypted program data for output;

in an encrypted program output mode,

re-encrypting said broadcast encryption key using a second algorithm to provide an encrypted playback key for use in decrypting encrypted program data recovered from a storage medium; and

formatting said encrypted playback key together with said associated broadcast encrypted program data to form encrypted program data for output; and

excluding said broadcast encrypted encryption key from said decrypted program data and said encrypted program data for output.

5. A method according to claim 4, wherein said excluding step includes the step of

substituting null data for said broadcast encrypted encryption key.

6. A method according to claim 4, including the step of adaptively incorporating data structure parameters in output data in said decrypted program output mode and different data structure parameters in output data in said encrypted program output mode, in response to said user generated data.

7. A method according to claim 5, wherein said null data is substituted for said broadcast encrypted encryption key within a data field selected from one of the following data fields: an MPEG Adaptation field; an MPEG Packetized Elementary Stream (PES) field; an MPEG Digital Storage Media Control

Command (DSMCC) field; Digital Satellite System (DSS™) auxiliary packet data field; and a non-MPEG data field.

8. A method according to claim 4, wherein said formatting step includes the step of
replacing said broadcast encrypted encryption key with said encrypted playback key.

9. A method according to claim 4, wherein
said user generated data also selects a) the storage device type, and b) a particular program to be stored.

10. In a video decoder for receiving and processing digital video data for output, a method for adaptively processing program representative data from an input datastream containing a broadcast encrypted encryption key and associated broadcast encrypted program data in a first mode and an encrypted playback encryption key and associated encrypted program data recovered from a storage medium in a second mode, comprising the steps of:

receiving user generated data for selecting one of (a) said first mode, and (b) said second mode;

in response to said user generated data, selecting between

a) a first algorithm for processing said broadcast encrypted encryption key to provide a broadcast encryption key for use in decrypting said broadcast encrypted program data, and

b) a second algorithm for processing said encrypted playback encryption key to obtain said playback encryption key for use in decrypting said encrypted program data recovered from a storage medium;

in said first mode,

decrypting said broadcast encrypted program data using said broadcast encryption key to provide decrypted program data for output; and

excluding said broadcast encrypted encryption key from said decrypted program data in said data for output;

in said second mode.

decrypting said encrypted program data recovered from a storage medium using said playback encryption key to provide decrypted program data for output; and providing said output data produced in one of said first and second modes to a device for display.

11. A method according to claim 10, wherein said selecting step comprises selecting between said first and second algorithms contained in an electronic device insertable into said video decoder.

12. A method according to claim 10, including the step of adaptively incorporating data structure parameters in said output data produced in one of said first and second modes.
