A stabilization device for bone parts or vertebrae includes two bone anchoring devices for anchoring in the bone parts or vertebrae. At least one of the bone anchoring devices includes an anchoring element with an anchoring section for anchoring in a bone part or a vertebra and a head, and a receiving part for receiving a stabilization rod. The receiving part has a seat for receiving the head so that the head can pivot with respect to the receiving part. The stabilization device includes a first pressure element which is movable in the receiving part so that it can be pressed onto the head to lock the angular position of the head. The stabilization device includes at least two stabilization rod sections, and at least two guiding channels within the receiving part which have a distance from each other for guiding through the at least two stabilization rod sections so that the rod sections do not touch each other.
BONE ANCHORING DEVICE AND
STABILIZATION DEVICE FOR BONE PARTS
OR VERTEBRAE COMPRISING SUCH A
BONE ANCHORING DEVICE

CROSS-REFERENCE TO RELATED
APPLICATION(S)

[0001] The present application is a continuation of U.S. patent application Ser. No. 12/571,299, filed Sep. 30, 2009, which claims the benefit of U.S. Provisional Patent Application Ser. No. 61/103,858, filed Oct. 8, 2008, the contents of which are hereby incorporated by reference in their entirety, and claims priority from European Patent Application No. 08 017 644.9, filed Oct. 8, 2008, the contents of which are hereby incorporated by reference in their entirety.

BACKGROUND

[0002] The invention relates to a bone anchoring device, in particular to a polyaxial bone screw which is connected to two stabilization rods and to a stabilization device having such a bone anchoring device, in particular for the stabilization of the spine.

[0003] A dynamic stabilization device for bones, in particular for vertebrae, is described in US 2004/0049190 A1. The stabilization device includes two bone anchoring elements, at least one of which is a polyaxial bone screw and a rigid rod with a longitudinal axis connecting them. An elastic element is inserted between the two bone anchoring elements. The elastic element acts on the bone anchoring elements to exert a force in a direction of the longitudinal axis. One of the bone anchoring elements is fixedly connected to the rod to prevent translational movement of the rod and the other bone anchoring element is slidably connected to the rod.

[0004] EP 1 800 614 A1 describes a dynamic stabilization device for bones or for vertebrae having at least two bone anchoring elements and at least one connection element in the form of an elastic loop connecting the bone anchoring elements. In one embodiment, the bone anchoring element is in the form of a polyaxial bone screw having a receiving part which accommodates to two elastic loops each of which can be connected to a second bone anchoring element.

[0005] Based on the foregoing, there is a need to provide a bone anchoring device and a stabilization device comprising such a bone anchoring device which allows the dynamic stabilization of bone parts or vertebrae and which allows a variable design of elastic properties of the dynamic stabilization device.

SUMMARY

[0006] The provision of a modular double-rod, i.e., two rods, allows to design the bone anchoring device more compact in terms of the height of the bone anchoring device, since each rod can be designed smaller than a single rod. The low profile cross-section of two rods compared to one single rod has also the advantage that the stiffness of the rods is enhanced. The stability in view of bending or torsional loads of the double-rod system is also enhanced.

[0007] The dynamic properties of the stabilization device can be adjusted by selecting appropriate rods and/or adjusting the sliding motion of the rods by stops and/or dampening elements. The dynamic properties of the rods can vary. For example the rods can have the same or different elastic properties. They can be made of the same or different material.

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] FIG. 1 shows a perspective side view of the stabilization device.

[0009] FIG. 2 shows a perspective exploded view of the stabilization device.

[0010] FIG. 3 shows an exploded view of the bone anchoring device according to a first embodiment.

[0011] FIG. 4 shows a perspective view of the bone anchoring device of FIG. 3 in an assembled state.

[0012] FIG. 5 shows a perspective view from the side of the first pressure element in a first embodiment.

[0013] FIG. 6 shows a perspective view of the second pressure element in a first embodiment.

[0014] FIG. 7 shows a partially sectional view of the bone anchoring device with the first and second pressure element according to the first embodiment.

[0015] FIG. 8 shows a partially sectional view of the bone anchoring device with the first and second pressure element according to a second embodiment.

[0016] FIG. 9 shows an exploded perspective view of the bone anchoring device with a first and second pressure element according to a third embodiment.

[0017] FIG. 10 shows a perspective view of the bone anchoring device of FIG. 9 in an assembled state.

[0018] FIG. 11 shows a perspective view of a rod according to another embodiment.

DETAILED DESCRIPTION

[0019] The invention is now described in detail with reference to the embodiment of the stabilization device shown in FIGS. 1 to 8. The stabilization device includes a first polyaxial pedicle screw 1, a second pedicle screw 2 and two rods 3a, 3b connecting them for stabilizing two adjacent vertebrae. The two rods 3a, 3b may be separate rods as shown in FIG. 2. Alternatively, as shown in FIG. 11, the rods 3a, 3b may be connected or formed in one-piece to define a single rod 3.

[0020] On each rod a spring element 4a, 4b is provided and the rods 3a, 3b are connected by rod connectors 5, 6. The rods 3a, 3b are fixedly clamped in the second pedicle screw 2 and can slide through the first pedicle screw 1 as shown by the arrows. The sliding motion is limited by means of the rod connector 6 which connects the free ends of the rods 3a, 3b and acts as a stop. The springs 4a, 4b and the rod connector 5 limit the sliding motion of the rods 3a, 3b relative to the first pedicle screw 1 in the direction of the second pedicle screw 2. The springs provide elastic damping. The rod connectors 5, 6 are sleeve shaped with two channels 5a, 5b, 6a, 6b, respectively, for guiding through the rods 3a, 3b. The distance of the channels corresponds to the distance of the rods in which they are guided through the pedicle screws. The rod connectors 5, 6 connect the rod 3a, 3b by means of a press-fit connection i.e. the diameter of the channels is selected such that the rods are firmly connected. The rod connectors 5, 6 can be made of an elastomer material or any other body compatible material.

[0021] The springs 4a, 4b in this embodiment are shown as helical springs encompassing the rods 3a, 3b like sleeves. They can be made of any body compatible material, in particular of titanium, nickel titanium alloys, for example nitinol, or other materials.

[0022] The rods 3a, 3b exhibit a flexibility under forces having a component perpendicular to the rod axis, such as bending forces. For this purpose the rods are made of non-
compressible materials, such as stainless steel, titanium, nickel titanium alloys, such as nitinol, PEEK or carbon reinforced PEEK or other body compatible materials. [0023] It should be noted that the rod connectors and the springs are only examples for the function of connecting the two rods, providing a stop and providing a dampening to the sliding motion.

[0024] Next, the first pedicle screw 1 will be described in detail with reference to FIGS. 3 to 7. The pedicle screw 1 comprises a screw element 10 with a threaded shank 11 and a spherically segment-shaped head 12. At the free end of the head 12 a recess 13 is provided for engagement with a tool. The pedicle screw 1 further comprises a receiving part 20 with a first end 21 and a second 22 and a coaxial bore 23 extending from the first end in the direction of the second end. At the second end 22 the bore 23 tapers to provide an opening and a seat 24 for the screw head 12 as shown in particular in FIG. 7.

[0025] The receiving part 20 further comprises a recess 25 extending from the first end 21 in the direction of the second end 22 which provides a channel through the receiving part in a direction perpendicular to the bore axis of bore 23 for guiding through the rods 3a, 3b. The recess provides two free legs 26a, 26b. Near the first end 21 the free legs 26a, 26b have an internal thread 27 for cooperation with a fixation screw 30. The screw element 10 and the receiving part 20 as well as the fixation screw 30 are made of a rigid body compatible material, such as a body compatible metal like stainless steel or titanium or a titanium alloy, such as nitinol.

[0026] For locking the head 12 and in consequence the angular position of the screw element 10 within the seat 24 of the receiving 20 a first pressure element 40 and a second pressure element 50 are provided. The first pressure element 40 and the second pressure element 50 also form guiding elements for guiding the rods 3a, 3b through the receiving part 20. The first pressure element 40 has a substantially cylindrical body part 41 which is sized such that the first pressure element 40 can be inserted in the receiving part and moved in an axial direction within the bore 23. At its side facing the head 12 of the screw element the first pressure element 40 comprises a cylindrical recess 42 shown in FIG. 7 in which a cylindrical insert 43 is provided. The insert 43 has on its side facing the head 12 of the screw element a spherical recess 44 the radius of which fits to the radius of spherical head 12 of the screw element.

[0027] The first pressure element 40 further comprises a cuboid body part 45 which is shaped so as to fit in the recess 25 of the receiving part 20 as shown in particular in FIGS. 3 and 4. The width of the body part 45 corresponds to the width of the recess 25 and the length is selected such that the first pressure element is flush with the outer surface 28 of the receiving part 20 as shown in FIG. 4. On its side opposite to the recess 42 the cuboid body part includes two cylinder segment-shaped recesses 46a, 46b the cylinder radius of which is slightly larger than the radius of the rods 3a, 3b. The recesses 46a, 46b extend perpendicular to the axis of the coaxial bore 23 of the receiving part 20. The recesses 46a, 46b form channels for receiving the rods 3a, 3b. Since the recesses 46a, 46b are spaced apart from each other a rib 47 is formed between them. The depth of the recesses 46a, 46b is preferably slightly larger than the radius of the rods 3a, 3b. The first pressure element 40 also has a coaxial bore 48 for providing access to the head 12 of the screw element with a tool. Similarly, the cylindrical insert 43 has a coaxial bore 49. The cylindrical body part 41 and the cuboid body part 25 are shown to be made in one piece so that cylindrical segment-shaped flanges 41a, 41b are provided on each side of the channel 46a, 46b. The flanges facilitate the guidance of the first pressure element 40 within the receiving part 20. The cuboid body part 45 prevents rotation of the first pressure element within the receiving part once the first pressure element is inserted into the recess 25.

[0028] The second pressure element 50 is substantially cuboid shaped with a width and length corresponding to that of the cuboid body part 45 of the first pressure element 40. Therefore, it also fits into the recess 25 of the receiving part. On its long sides it comprises two cylindrical segment-shaped flanges 51a, 51b corresponding to the flanges 41a, 41b of the first pressure element. On its side opposite to the first pressure element 40, the second pressure element 50 comprises a cylindrical recess 52 and a coaxial cylindrical projection 53 in which a corresponding ring-shaped projection 31 and a cylindrical recess 32 of the fixation screw 30 engage, as shown in FIG. 7. Thereby, the fixation screw 30 can be rotatably connected to the pressure element 50.

[0029] On its side facing the first pressure element, the second pressure element 50 comprises two longitudinal cylinder segment-shaped recesses 56a, 56b which are complementary in their size and distance to the channels 46a, 46b of the first pressure element. The channels 56a, 56b are spaced apart by a rib 57.

[0030] In the assembled state shown in FIG. 7 the first pressure element presses via the insert 43 onto the head 12. The second pressure element 50 presses onto the first pressure element 40 thereby providing closed channels for the rods 3a, 3b which are accommodated therein with a gap 60 to the wall of the channel. Since the fixation screw 30 is rotatably connected to the second pressure element, the fixation screw 30 can be tightened when the second pressure element 50 is inserted.

[0031] The first pressure element and the second pressure element can be made of a material which facilitates sliding of the rods 3a, 3b. For example, the pressure elements can be made of titanium or a nickel titanium alloy which is coated or of PEEK or carbon reinforced PEEK. The insert 43 is preferably made of the same material as the head 12 of the screw, for example of a body compatible metal. Instead of providing the insert 43 the first pressure element itself can have a spherical recess to press onto the head. Instead of providing the first and second pressure element of a material which facilitates sliding or which is coated or treated to facilitate sliding, the rods 3a, 3b themselves can have a surface which facilitates sliding, for example a coated or otherwise treated surface.

[0032] The second pedicle screw 2 shown in FIGS. 1, 2 and 8 differs from the first pedicle screw 1 in the design of the first and second pressure elements. All other parts are identical and have the same reference numerals. Therefore, the description thereof is not repeated. The shape of the first pressure element 40 and of the second pressure element 50 of the second pedicle screw 2 is the same as that of the first pressure element 40 and the second pressure element 50 of the first pedicle screw 1. However, the size of the channels 46a, 46b, 56a, 56b is smaller than that of the channels and second pressure element of the first pedicle screw. The radius of the channels is adapted to the radius of the rods 3a, 3b and depth of the channels is smaller than the radius of the rods 3a, 3b such that, as shown in FIG. 8, in the assembled state the rods 3a, 3b are clamped between the first pressure element 40 and the second pressure element 50.
A second embodiment of the stabilization device is shown in FIGS. 9 and 10 without the rods. The second embodiment differs from the first embodiment described with reference to FIGS. 1 to 8 only in the shape of the first and second pressure elements 400, 500. The length of the channels 460a, 460b is smaller than the diameter of the cylindrical body part 410. Therefore, the first pressure element 400 and the second pressure element 500 are arranged completely within the cylindrical bore 23 of the receiving part.

Modifications of the above described embodiments are conceivable. For example, the pedicle screws and the design of the pressure elements can be such so that more than two rods can be accommodated. It is possible to use rods with different elastic properties. It is sufficient, if one of the pressure elements has the channels for guiding the rods, however, it is advantageous if the rods are guided from below and from the top by the channels. The shape of the lower part of the first pressure element can be flat, however, a shape adapted to the shape of the head of the screw is advantageous for distributing the pressure onto the head.

The fixation element can be a two-part fixation screw wherein the first screw element of a bushing type press onto the first pressure element for locking of the head one and a second screw element of a set screw type arranged within the first screw element press onto the second pressure element for fixation of the rods in the embodiment shown in FIG. 8.

The receiving part can be shaped as a top loader as shown in the figures or a bottom loader in which the screw element is introduced from the bottom, i.e. the second end of the receiving part.

The shank of the screw element does not have to have a thread. It can be in the form of a hook, a nail or can have barb elements for anchoring in the bone.

The springs can also be provided adjacent to the outer stop. It is also conceivable that the rods themselves have an axial elastic spring portion.

In use, first the screw elements of the pedicle screws 1, 2 which have been inserted into the receiving parts 20 are screwed into adjacent vertebrae. The first pressure elements can be preassembled so that after alignment of the receiving parts the rods can be inserted into the receiving part and the channels of the first pressure element, respectively. The rods can be inserted as well and can be inserted as a double-rod system. For specific clinical applications the first pedicle screw and the stop points in the direction the patient’s head. However, the arrangement of the pedicle screws depends on the specific clinical situation.

Next, after the receiving parts and the rods are aligned the angular position of the screw elements relative to the receiving parts is fixed by inserting the fixation screw together with the second pressure element and tightening the fixation screw. In the case of the second pedicle screw 2 as shown in FIGS. 1, 2 and 8 the rods 3a, 3b are fixed simultaneously with the screw head 12. In the case of the first pedicle screw only the head 12 of the screw element is fixed while the rods can still slide within the channels.

As shown in FIG. 1 the rods can slide through the receiving part of the first pedicle screw during flexion or extension of the spinal motion segment, whereby the sliding movement is limited by the rod connectors 6 and 5 acting as stops and damped by the springs 4a, 4b. Simultaneously, the rods may experience bending forces and can bend to some extend provided by the flexibility of the material of the rods.

A polyaxial bone anchoring device comprising: an anchoring element comprising a shank for anchoring a bone part or a vertebra and a head; a receiving part configured to pivotally receive the head, the receiving part having a first end, a second end opposite to the first end, a coaxial bore, a first recess and a second recess each adjacent to the first end for receiving a rod, and a central axis extending through the first end and the second end, the receiving part comprising two legs separated by the coaxial bore and the first and second recesses, a longitudinal axis of the recesses being substantially perpendicular to the central axis; a first clamping part having a rod supporting surface that extends from the coaxial bore into the first recess when assembled in the receiving part; a second clamping part configured to exert pressure on the rod when the rod is in the coaxial bore; and a locking device configured to exert pressure on the second clamping part to secure the rod in the coaxial bore; wherein, when the bone anchoring device is assembled, the first clamping part is located between the head of the anchoring element and the second clamping part.

The polyaxial bone anchoring device of claim 29, wherein the rod supporting surface has a longitudinal axis perpendicular to the central axis.

The polyaxial bone anchoring device of claim 29, wherein the first clamping part further comprises a coaxial bore that is coaxial to the central axis.

The polyaxial bone anchoring device of claim 29, wherein rod supporting surface of the first clamping part extends from the coaxial bore of the receiving part into the second recess.

The polyaxial bone anchoring device of claim 32, wherein the second clamping part extends from the coaxial bore of the receiving part into the first recess and into the second recess.

The polyaxial bone anchoring device of claim 29, wherein the second clamping part has a rod facing surface having a longitudinal axis perpendicular to the central axis.

The polyaxial bone anchoring device of claim 29, wherein respective free ends of the first clamping part and the second clamping part extend into the first recess such that the free ends are flush with the outer surface of the receiving part.

The polyaxial bone anchoring device of claim 29, wherein the second clamping part is configured to be rotatably coupled to the locking device.

The polyaxial bone anchoring device of claim 29, wherein the first clamping part further comprises a portion that is configured to exert pressure on the head.

The polyaxial bone anchoring device of claim 37, wherein the first portion has a recess at a side opposite to the rod supporting surface and the recess is configured to accommodate a portion of the head.

A spinal stabilization system comprising at least two polyaxial bone anchoring devices according to claim 29 and a rod, wherein the rod comprises a nickel-titanium alloy.

The polyaxial bone anchoring device of claim 37, wherein the first portion has a cylindrical outer surface configured to be received in the coaxial bore and a spherical inner surface configured to engage the head.
