The present invention relates to organic compounds useful for therapy and/or prophylaxis in a human, and in particular to Hepatitis B virus (HBV) inhibitors by targeting on HBV capsid for the treatment of HBV infection.

5 FIELD OF THE INVENTION

HBV is a species of the hepadnaviridae family of viruses. HBV is a serious public health problem worldwide, with more than 400 million people especially in Asia-pacific regions chronically infected by this small enveloped DNA virus. Although most individuals seem to resolve the infection following acute symptoms, 15-40% of HBV patients will finally develop clinical diseases during their lifespan, most notably, hepatitis, liver cirrhosis, and hepatocellular carcinoma. Every year 500,000 to 1 million people die from the end stage of liver diseases caused by HBV infection.

HBV lifecycle begins with the binding of the “Dane” particle with an unidentified receptor on the surface of hepatocyte. Following entry, viral genome is delivered into nucleus where a covalently closed circular DNA (cccDNA) is formed through DNA repair of viral relaxed circular DNA. Unlike the mechanisms of most other DNA viruses, HBV cccDNA replicates through the retrotranscription of a 1.1-genome unit-length RNA copy (pregenomic RNA). Viral pregenomic RNA interacts with other two viral components, capsid protein and polymerase, as well as some host factors, to form capsid particles where viral DNA replication occurs. Most copies of the encapsidated genome then efficiently associate with the envelope proteins for virion assembly and secretion; a minority of these genomes is shunted to the nucleus, where they are converted to cccDNA.

Currently, there are two types of anti-HBV agents on the market, nucleoside (tide) analogs targeting viral polymerase (lamivudine, adefovir, tenofovir, telbivudine and entecavir) and interferon modulating host immune functions. Mutations in the primary sequence of the polymerase that confer resistance to lamivudine and adefovir have been identified clinically and underlie a rebound of serum virus titers that 70% of treated patients experience within 3 years of
the start of lamivudine therapy. Although resistance to telbivudine, adefovir, and entecavir occurs more rarely, it has been recorded. Interferon alpha is the other major therapy available for hepatitis B, but it is limited by a poor long-term response and debilitating side effects. Some viral genotypes do not show good responses to interferon therapy. Now, the standard of clinic
cure of HBV infection is the loss and/or seroconversion of HBsAg. The majority (around or more than 90%) of treated patients fail to achieve this goal. This drawback is mainly due to the presence of a stable pool of viral cccDNA in nucleus that doesn’t replicate itself, therefore, shows no accessibility to nucleoside (tide) analogs.

Hence, there is certainly a medical need for treatments with improved characteristics and
for a diversity of approaches in the development of therapies for HBV infection.

HBV capsid protein plays essential roles in HBV replication. HBV has an icosahedral core comprising of 240 copies of the capsid (or core) protein. The predominant biological function of capsid protein is to act as a structural protein to encapsidate pre-genomic RNA and form immature capsid particles in the cytoplasm. This step is prerequisite for viral DNA replication.

The HBV capsid spontaneously self-assembles from many copies of core dimers present in the cytoplasm. It has been shown that the formation of a trimeric nucleus and the subsequent elongation reactions occur by adding one dimeric subunit at a time until it is complete. Besides this function, capsid protein regulates viral DNA synthesis through different phosphorylation status of its C-terminal phosphorylation sites. When a near full-length relaxed circular DNA is formed through reverse-transcription of viral pregenomic RNA, an immature capsid becomes a mature capsid. On one hand, capsid protein might facilitate the nuclear translocation of viral relaxed circular genome by means of the nuclear localization signals located in the Arginine-rich domain of the C-terminal region of capsid protein. In nucleus, as a component of viral cccDNA minichromosome, capsid protein could play a structural and regulatory role in the functionality of cccDNA minichromosomes. Capsid protein also interacts with viral large envelope protein in endoplasmic reticulum and triggers the release of intact viral particles from hepatocytes.

There has been a couple of capsid related anti-HBV inhibitors reported. For example, phenylpropenamide derivatives, including compounds named AT-61 and AT-130 (Feld J. et al. Antiviral Research 2007, 168-177), and a class of thiazolidin-4-ones from Valeant R&D (WO2006/033995), have been shown to inhibit pgRNA packaging. A recent study suggested that phenylpropenamides are, in fact, accelerators of HBV capsid assembly, and their actions result in the formation of empty capsids. These very interesting results illustrate the importance of the kinetic pathway in successful virus assembly.
Heteroaryl dihydropyrimidines or HAP, including compounds named Bay 41-4109, Bay 38-7690 and Bay 39-5493, were discovered in a tissue culture-based screening (Deres K. et al. Science 2003, 893). These HAP analogs act as synthetic allosteric activators and are able to induce aberrant capsid formation that leads to degradation of the core protein. HAP analogs also reorganized core protein from preassembled capsids into noncapsid polymers, presumably by interaction of HAP with dimers freed during capsid ‘breathing’, the transitory breaking of individual intersubunit bonds. Bay 41-4109 was administered to HBV infected transgenic mouse or humanized mouse models and demonstrated in vivo efficacy with HBV DNA reduction (Deres K. et al. Science 2003, 893; Brezillon N. et al. PLoS ONE 2011, e25096). It was also shown that bis-ANS, a small molecule that acts as a molecular ‘wedge’ and interferes with normal capsid-protein geometry and capsid formation (Zlotnick A. et al. J. Virol. 2002, 4848-4854).

DETAILED DESCRIPTION OF THE INVENTION

Particular “C₄₋₆-alkyl” groups are methyl, ethyl, isopropyl and tert-butyl.

The term “-C₃H₂₅” alone or in combination signifies a saturated, linear or branched chain alkyl group containing from 1 to 6 carbon atoms, particularly from 1 to 4 carbon atoms.

The term “cycloalkyl”, alone or in combination, refers to a saturated carbon ring containing from 3 to 7 carbon atoms, particularly from 3 to 6 carbon atoms, for example,
cyclopropyl, cyclobutyl, cyclopentyl, cyclohexyl, cycloheptyl and the like. Particular "cycloalkyl" groups are cyclopropyl, cyclopentyl and cyclohexyl.

The term "carboxy" alone or in combination refers to the group -COOH.

The compounds according to the present invention may exist in the form of their pharmaceutically acceptable salts. The term "pharmacaceutically acceptable salt" refers to conventional acid-addition salts or base-addition salts that retain the biological effectiveness and properties of the compounds of formula I and are formed from suitable non-toxic organic or inorganic acids or organic or inorganic bases. Compound with favorable pharmacokinetics is more likely to be efficacious and safe. It is very important for a drug to have a moderate or low clearance and a reasonable half-life, as this often leads to a good oral bioavailability and high systemic exposure. Reducing the clearance of a compound or drug could reduce the daily dose required for efficacy and therefore give a better efficacy and safety profile. It is also very important for HBV infection treatment compound to show good liver exposure since this is the targeted organ. As shown in Table 4, compounds of the present invention exhibit good mouse SDPK profiles: low to moderate clearance, good exposure at low dose in both plasma and liver, and good bioavailability. As shown in Table 5, compounds of the present invention also exhibit low clearance in *in vitro* human hepatic microsome stability assay.

The single dose PK parameters of Bay 41-4109, Example 2, Example 5 and Example 16 in mouse plasma and liver are shown in Table 4.

The aqueous solubility is an important physico-chemical property that plays a significant role in various physical and biological processes. It is desirable to have good solubility which enables good permeability and gastric and intestinal absorption, linear dose proportionality, less PK variability, and easy formulation for PD/PK studies. At different stages of the drug discovery/development process solubility has to be determined and especially in the early phases (lead generation to lead optimization) high throughput methods are needed. Lyophilisation solubility assay (Lysa) is a well adopted high throughput assay to measure compound solubility in industry.

Results of Lysa are given in Table 6.

Based on FDA guidance, in order to support clinical testing in humans, the assessment of acceptable risk-benefit has to be achieved by providing clear evidence of in vitro antiviral activity (EC<sub>50</sub>) and cytotoxicity (CC<sub>50</sub>). It is important to establish that an investigational product
has antiviral activity at concentrations that can be achieved in vivo without inducing toxic effects to cells. Furthermore, in a cell culture model, apparent antiviral activity of an investigational product can be the result of host cell death after exposure to the product. The relative effectiveness of the compound in inhibiting viral replication compared to inducing cell death is defined as the selectivity index (CC\textsubscript{50} value/EC\textsubscript{50} value). It is desirable to have a high selectivity index giving maximum antiviral activity with minimal cell toxicity.

Results of CC\textsubscript{50} and the corresponding selectivity index are given in Table 7.

**SYNTHESIS**

The compounds of the present invention can be prepared by any conventional means. Suitable processes for synthesizing these compounds as well as their starting materials are provided in the schemes below and in the examples. All substituents, in particular, Rᵢ to R⁴, and A are as defined above unless otherwise indicated. Furthermore, and unless explicitly otherwise stated, all reactions, reaction conditions, abbreviations and symbols have the meanings well known to a person of ordinary skill in organic chemistry.

A. General synthetic route for Compound **Ia, Iaa**, and **Iab** (Scheme 1)

Scheme 1
Compounds of interest Ia, Iaa and Iab can be prepared according to Scheme 1. Starting with acetyl acetate IIa, aldehyde III and amidine IV, dihydropyrimidine Va can be synthesized through a one-pot condensation reaction. Bromination of Compound Va provides bromide Vla. Coupling bromide Vla with cyclic amino acid VII generates compound of interest Ia. Further chiral separation of Ia affords two enantiomerically pure compounds of interest Iaa and Iab.

Dihydropyrimidine Va can be prepared from condensation and cyclization sequence of acetyl acetate II, aldehyde III and amidine IV. The reaction can be carried out in a suitable alcoholic solvent such as trifluoroethanol in the presence of a base like potassium acetate under a heating condition over several hours.
Bromide VIa can be prepared by reaction of Va with a bromination reagent, such as N-bromosuccinimide, in a suitable inert solvent such as carbon tetrachloride at 80-100 degrees Celsius for about 1 hour.

Compound of interest Ia can be obtained by coupling bromide VIa with cyclic amino acid VII. The reaction is typically performed in a suitable solvent like 1,2-dichloroethane at room temperature over several hours in the presence of an organic base such as N,N-diisopropylethylamine.

Compounds of further interest Iaa and Iab are obtained by preparative HPLC separation of diastereomeric mixture Ia. The stereochemistry of Iaa is determined by comparing its 1H NMR data and SFC retention time with the same compound made by synthetic route B.

B. An alternative general synthetic route for Compound Iaa (Scheme 2)

Scheme 2

Alternatively, compound of interest Iaa can be prepared according to Scheme 2. A one-pot reaction between acetyl acetate II, aldehyde III and amidine IV gives dihydropyrimidine Va. (−)
Enantiomer Vaa is then obtained by SFC chiral separation of Va and its stereochemistry is determined by comparing its SFC retention time with one of its particular Compound E which stereochemistry is determined by X-ray diffraction study (Figure 1).

Bromination of Vaa then affords VIaa. Coupling VIaa with a suitable cyclic amino acid VII gives the compound of interest Iaa.

The synthetic procedure from Vaa to Iaa is identical to what is described in Scheme 1 except that chiral intermediate Vaa is used instead of racemic Va.

C. General synthetic route for Compound IV (Scheme 3)

Any commercial unavailable amidine building block IV can be prepared from the corresponding nitrile VIII by first reacting with sodium methoxide followed by treatment with ammonium chloride as described in Scheme 3.

This invention also relates to a process for the preparation of a compound of formula I comprising the reaction of

(a) a compound of formula (XZ)

(b) a compound of formula (YZ)
under chiral separation condition;
wherein $R^1$ to $R^4$ and $A$ are defined above unless otherwise indicated.

5 In step (a), the base can be for example $N,N$-diisopropylethylamine.

A compound of formula I when manufactured according to the above process is also an object of the invention.

10 PHARMACEUTICAL COMPOSITIONS AND ADMINISTRATION

The invention also relates to a compound of formula I for use as therapeutically active substance.

Another embodiment provides pharmaceutical compositions or medicaments containing the compounds of the invention and a therapeutically inert carrier, diluent or excipient, as well as methods of using the compounds of the invention to prepare such compositions and medicaments. In one example, compounds of formula I may be formulated by mixing at ambient temperature at the appropriate pH, and at the desired degree of purity, with physiologically acceptable carriers, i.e., carriers that are non-toxic to recipients at the dosages and concentrations employed into a galenical administration form. The pH of the formulation depends mainly on the particular use and the concentration of compound, but preferably ranges anywhere from about 3 to about 8. In one example, a compound of formula I is formulated in an acetate buffer, at pH 5. In another embodiment, the compounds of formula I are sterile. The compound may be stored, for example, as a solid or amorphous composition, as a lyophilized formulation or as an aqueous solution.

25 Compositions are formulated, dosed, and administered in a fashion consistent with good medical practice. Factors for consideration in this context include the particular disorder being
treated, the particular human being treated, the clinical condition of the individual patient, the
cause of the disorder, the site of delivery of the agent, the method of administration, the
scheduling of administration, and other factors known to medical practitioners. The “effective
amount” of the compound to be administered will be governed by such considerations, and is the
minimum amount necessary to the suppression of serum HBV DNA levels, or HBeAg
seroconversion to HBeAb, or HBsAg loss, or normalization of alanine aminotransferase levels
and improvement in liver histology. For example, such amount may be below the amount that is
toxic to normal cells, or the human as a whole.

In one example, the pharmaceutically effective amount of the compound of the invention
administered parenterally per dose will be in the range of about 0.01 to 100 mg/kg, alternatively
about 0.1 to 20 mg/kg of patient body weight per day, with the typical initial range of compound
used being 0.3 to 15 mg/kg/day. In another embodiment, oral unit dosage forms, such as tablets
and capsules, contain from about 0.1 to about 1000 mg of the compound of the invention.

The compounds of the invention may be administered by any suitable means, including
oral, topical (including buccal and sublingual), rectal, vaginal, transdermal, parenteral,
subcutaneous, intraperitoneal, intrapulmonary, intradermal, intrathecal and epidural and
intranasal, and, if desired for local treatment, intralesional administration. Parenteral infusions
include intramuscular, intravenous, intraarterial, intraperitoneal, or subcutaneous administration.

The compounds of the present invention may be administered in any convenient
administrative form, e.g., tablets, powders, capsules, solutions, dispersions, suspensions, syrups,
sprays, suppositories, gels, emulsions, patches, etc. Such compositions may contain components
conventional in pharmaceutical preparations, e.g., diluents, carriers, pH modifiers, sweeteners,
bulking agents, and further active agents.

A typical formulation is prepared by mixing a compound of the present invention and a
carrier or excipient. Suitable carriers and excipients are well known to those skilled in the art and
are described in detail in, e.g., Ansel, Howard C., et al., Ansel’s Pharmaceutical Dosage Forms
and Drug Delivery Systems. Philadelphia: Lippincott, Williams & Wilkins, 2004; Gennaro,
Williams & Wilkins, 2000; and Rowe, Raymond C. Handbook of Pharmaceutical Excipients.
Chicago, Pharmaceutical Press, 2005. The formulations may also include one or more buffers, stabilizing agents, surfactants, wetting agents, lubricating agents, emulsifiers, suspending agents, preservatives, antioxidants, opaquing agents, glidants, processing aids, colorants, sweeteners, perfuming agents, flavoring agents, diluents and other known additives to provide an elegant presentation of the drug (i.e., a compound of the present invention or pharmaceutical composition thereof) or aid in the manufacturing of the pharmaceutical product (i.e., medicament).

An example of a suitable oral dosage form is a tablet containing about 0.1 mg to 1000 mg of the compound of the invention compounded with about 90 mg to 30 mg anhydrous lactose, about 5 mg to 40 mg sodium croscarmellose, about 5 mg to 30 mg polyvinylpyrrolidone (PVP) K30, and about 1 mg to 10 mg magnesium stearate. The powdered ingredients are first mixed together and then mixed with a solution of the PVP. The resulting composition can be dried, granulated, mixed with the magnesium stearate and compressed to tablet form using conventional equipment. An example of an aerosol formulation can be prepared by dissolving the compound, for example 5 mg to 400 mg, of the invention in a suitable buffer solution, e.g. a phosphate buffer, adding a tonicifier, e.g. a salt such sodium chloride, if desired. The solution may be filtered, e.g., using a 0.2 micron filter, to remove impurities and contaminants.

An embodiment, therefore, includes a pharmaceutical composition comprising a compound of Formula I, or a stereoisomer or pharmaceutically acceptable salt thereof. In a further embodiment includes a pharmaceutical composition comprising a compound of Formula I, or a stereoisomer or pharmaceutically acceptable salt thereof, together with a pharmaceutically acceptable carrier or excipient.

PREPARATIVE EXAMPLES

Example 1 and 2:
6-((S)-2-Carboxy-4,4-difluoro-pyrrolidin-1-ylmethyl)-4-(2-chloro-4-fluoro-phenyl)-2-thiazol-2-yl-1,4-dihydro-pyrimidine-5-carboxylic acid methyl ester (Example 1) and (R)-6-((S)-2-carboxy-4,4-difluoro-pyrrolidin-1-ylmethyl)-4-(2-chloro-4-fluoro-phenyl)-2-thiazol-2-yl-1,4-dihydro-pyrimidine-5-carboxylic acid methyl ester (Example 2)

Procedure A:

The title compounds were prepared according to the general synthetic routes shown in Scheme 1 and Scheme 3. A detailed synthetic route is provided in Scheme 4.
Preparation of Compound A₁:

To a stirred solution of thiazole-2-carbonitrile (1.5 g, 14 mmol) in 5 mL of dry MeOH was added dropwise a solution of sodium methoxide (0.74 g, 14 mmol) in 10 mL of dry methanol. The reaction mixture was stirred at room temperature until the disappearance of starting material which was checked by LC/MS. After that, ammonium chloride (1.5 g, 28 mmol) was added in one portion and the reaction mixture was stirred overnight. The undissolved material was removed by filtration and the filtrate was concentrated to afford thiazole-2-carboxamidine hydrochloride (Compound A₁) as a grey solid which was used directly in the next step without further purification. MS: calc’d 128 (MH⁺), measured 128 (MH⁺).

Preparation of Compound B:

To a stirred solution of thiazole-2-carboxamidine hydrochloride (0.13 g, 1.0 mmol), methyl acetoacetate (0.12 g, 1.0 mmol) and 2-chloro-5-fluorobenzaldehyde (0.16 g, 1.0 mmol) in CF₃CH₂OH (8 mL) was added potassium acetate (0.20 g, 2.0 mmol). The reaction mixture was either refluxed for 16 hrs or heated at 150 °C in microwave oven for 2 hours. After it was cooled to room temperature, the reaction mixture was concentrated and the residue was dissolved in ethyl acetate and washed with brine. The organic layer was dried over sodium sulfate and concentrated, and the residue was purified by column chromatography (ethyl acetate/petroleum ether is from 1/4 to 1/2) to afford 4-(2-chloro-4-fluoro-phenyl)-6-methyl-2-thiazol-2-yl-1,4-dihydro-pyrimidine-5-carboxylic acid methyl ester (Compound B) as a yellow solid. MS: calc’d (MH⁺) 366, measured (MH⁺) 366. ¹H NMR (DMSO-d₆, 400 MHz): δ ppm 9.98 (s, 1H), 7.97 (d, J = 4.0 Hz, 1H), 7.90 (d, J = 4.0 Hz, 1H), 7.41 (dd, J = 8.0, 4.0 Hz, 1H), 7.35 (dd, J = 8.0, 8.0 Hz, 1H), 7.18 (td, J = 8.0, 4.0 Hz, 1H), 5.98 (s, 1H), 3.53 (s, 3H), 2.47 (s, 3H).

MS: calc’d 429 (MH⁺), measured 429 (MH⁺).

The reaction mixture was stirred at room temperature until the disappearance of starting material which was checked by LC/MS. The mixture was diluted with EtOAc (50 mL) and washed successively with saturated aqueous NH₄Cl solution and brine. The organic layer was separated and dried over Na₂SO₄. The solvent was concentrated in vacuo and the crude product was purified by prep-HPLC to give 6-((S)-2-carboxy-4,4-difluoro-pyrrolidin-1-ylmethyl)-4-(2-chloro-4-fluoro-phenyl)-2-thiazol-2-yl-1,4-dihydropyrimidine-5-carboxylic acid methyl ester (Example 1).

temperature until the disappearance of starting material which was checked by LC/MS. The
mixture was diluted with EtOAc (50 mL) and washed successively with saturated aqueous
NH₄Cl solution and brine. The organic layer was separated and dried over Na₂SO₄. The solvent
was concentrated in vacuo and the crude product was purified by prep-HPLC to give (R)-6-((S)-

To a stirred solution of 2-bromo-1-cyclopropyl-ethanone (16 g, 100 mmol) in EtOH (150 mL) was added successively thiourea (8.0 g, 105 mmol) and Cu(OAc)$_2$ (0.90 g, 5.0 mmol) at room temperature. 2-Bromo-3,4-difluorobenzoic acid (3.7 g, 16 mmol, Eq: 1.00) was dissolved in anhydrous THF (20 ml) and the solution was cooled to 0 °C. BH$_3$THF (62.6 ml, 62.6 mmol, Eq: 4) was added dropwise. The resulting solution was allowed to warm up to room temperature and stirred overnight. The solution was cooled with an ice bath, and then 10% aqueous Na$_2$CO$_3$ (30mL) was added slowly. The suspension was concentrated in vacuo to give a white solid. The residue was acidified with 3M aqueous HCl solution (100 mL), diluted with dichloromethane (50 mL), and the mixture was filtered through Celite. The organic layers was separated and dried over sodium sulfate, and then followed by a filtration. Resulting filtrate was concentrated in vacuum to give an off-white solid AR (2.5 g). $^1$H NMR (DMSO) δ 7.46-7.53 (m, 1H), 7.35-7.41 (m, 1H), 4.51 (s, 2H), 4.44-4.58 (m, 2H)

Example 131: HBV inhibition assays

Cells and culture conditions:

HepG2.2.15 and HepDE19 are stably-transfected cell lines containing the HBV genome. Both cell lines are derived from the hepatoblastoma cell line Hep G2 (American Type Culture Collection, ATCC® HB-8065™) by the published procedures described in references: MA Selles et al. Proc. Natl. Acad. Sci. USA 1987, 84, 1005-1009 and H Guo et al. Journal of Virology 2007, 81, 12472-12484, respectively. Both cell lines were maintained in Dulbecco's modified Eagle's medium (DMEM)-F12 medium supplemented with 10% fetal bovine serum, 100 U/mL penicillin, 100 $\mu$g/mL streptomycin, and 0.5 mg/mL of G418.

While HepG2.2.15 cells constitutively support HBV replication and production of virus particles, HepDE19 cells are inducible by tetracycline. Addition of 1$\mu$g/mL tetracycline in
culture medium suppresses HBV replication in HepDE19 cells, whereas switching to tetracycline-free medium resumes this process.

**Anti-HBV activity in vitro:**

HepG2.2.15 cells were seeded into 96-well plates (3 × 10^4 cells in 100 μl media per well) and incubated overnight at 37 °C. The test compounds were serially half-log diluted in DMSO, then diluted 100 times in culture media. 100 μL diluted compounds were added into the plates to reach 0.5% final concentration of DMSO in every well. Five days after compound treatment, culture supernatant was collected for further analysis.

For quantitative PCR detection of extracellular HBV DNA, 100 μL culture supernatant was collected and processed in MagNA Pure 96 Nucleic Acid Purification System (Roche Applied Science) for viral DNA extraction. The extracted samples were subjected to HBV DNA quantification by qPCR. The effective compound concentration at which HBV replication is inhibited by 50% (EC50) was determined.

The compounds of the present invention were tested for their capacity to inhibit a HBV activity and activation as described herein. The Examples were tested in the above assays as described herein and found to have EC50 <0.10 μM in HepG2.2.15 assay. Particular compounds of formula I were found to have EC50 <0.02 μM in HepG2.2.15 assay (See Table 3).

**Cytotoxicity and selectivity index:**

In a cell culture model, apparent antiviral activity of a compound can be the result of host cell death after exposure to the compound. To determine whether the anti-HBV effect of a test compound is due to cytotoxicity, HepDE19 cells were seeded into 96-well plates (5 × 10^3 cells per well) and treated with compounds as described above for EC50 determination. Five days after treatment, cell viability was measured by addition of 20 μL of CCK-8 reagent. Two hours after incubation at 37°C, the absorbance at wavelengths of 450 nm and 630 nm (OD450 and OD630) was recorded by a plate reader. The concentration results in the death of 50% of the host cells (CC50) of each compound was determined (See Table 6).

The relative effectiveness of the compound in inhibiting viral replication compared to inducing cell death is defined as the selectivity index (CC50 value/EC50 value). It is desirable to have a high selectivity index giving maximum antiviral activity with minimal cell toxicity. Based on CC50 and EC50 data, selectivity indexes were determined as shown in Table 7.

Based on CC50 and EC50 data, selectivity indexes were determined as shown in Table 7.
Example 132: mouse SDPK description: The single dose PK in male ICR mouse was performed to assess their pharmacokinetic properties. Two groups of animals were dosed via either bolus intravenous (IV) or oral gavage (PO) of the respective compound. The animals for oral administration were fasted overnight prior to dosing and food was resumed 4 hours postdose. Blood samples (approximately 400 µL) were collected via cardiac puncture after euthanasia by carbon dioxide inhalation at 2 mins, 5 mins, 15 mins, 30 mins, 1 h, 2 hrs, 4 hrs, 6 hrs, 8 hrs, and 24 hrs postdose for IV group, and at 5 mins, 15 mins, 30 mins, 1 h, 2 hrs, 4 hrs, 6 hrs, 8 hrs, and 24 hrs postdose for PO group. Blood samples were placed into tubes containing sodium heparin and centrifuged at 8000 rpm for 6 minutes at 4°C to separate plasma from the samples. Following centrifugation, the resulting plasma was transferred to clean tubes for bioanalysis on LC/MS/MS. The pharmacokinetic parameters were calculated using non-compartmental module of WinNonlin® Professional 5.2.

Results of SDPK are given in Table 4.

Example 133: description of metabolic stability study: Human Microsomes were preincubated with test compound for 10 min at 37°C in 100 mM phosphate buffer, pH 7.4. The reactions were initiated by adding NADPH or NADPH regenerating system to give a final incubation volume of 400 µL. For NADPH system, the final incubations contained 1 µM test compound, 0.5 mg/mL liver microsomal protein, 1 mM NADPH in 100 mM phosphate buffer, pH 7.4. For the NADPH regenerating system, the final incubations contained 1 µM test compound, 0.5 mg/mL liver microsomal protein, 3 mM glucose 6-phosphate, 1 mM NADP, 3 mM MgCl₂ and 0.05 mg/mL glucose 6-phosphate dehydrogenase in 100 mM phosphate buffer, pH 7.4. After incubation times of 0, 3, 6, 9, 15 and 30 minutes at 37°C, 50 µL samples was removed and transferred to 150 µL methanol solution which was maintained at 4 °C containing 2µM tolbutamide (internal standard) to terminating the reaction. Following precipitation and centrifugation, the amount of compound remaining in the samples were determined by LC-MS/MS. Controls of no NADPH or NADPH regenerating system at zero and 30min were also prepared and analyzed.

Results of metabolic stability study in human microsome are given in Table 5.

Example 134: LYSA description: Samples are prepared in duplicate from 10 mM DMSO stock solutions. After evaporation of DMSO with a centrifugal vacuum evaporator, the residue is solved in 0.05 M phosphate buffer (pH 6.5), stirred for one hour and shaked for two hours. After
one night, the solutions is filtered using a microtiter filter plate and the filtrate and its 1/10
dilution are then analyzed by direct UV measurement or by HPLC-UV. In addition a four-point
calibration curve is prepared from the 10 mM stock solutions and used for the solubility
determination of the compounds. The results are in µg/mL. In case the percentage of sample
measured in solution after evaporation divided by the calculated maximum of sample amount is
bigger than 80% the solubility is reported as bigger than this value.

Results of Lysa are given in Table 6.
