(57) **ABSTRACT**

Embodiments of the invention relate to systems, methods, and computer program products for improved electronic discovery and custodian management. Embodiments herein disclosed provide for an enterprise wide e-discovery system that provides for data to be identified, located, retrieved, preserved, searched, reviewed and produced in an efficient and cost-effective manner across the entire enterprise system. In addition, by structuring management of e-discovery based on case/matter, custodian and data and providing for linkage between the same, further efficiencies are realized in terms of identifying, locating and retrieving data and leveraging results of previous e-discoveries with current requests.

FIG. 14

ELECTRONIC DISCOVERY SYSTEM**CROSS-REFERENCE TO RELATED APPLICATION**

This application is a continuation of U.S. patent application Ser. No. 12/627,791, entitled "Electronic Discovery System" filed Nov. 30, 2009.

Claim of Priority Under 35 U.S.C. §119

The present Application for Patent claims priority to Provisional Application No. 61/164,276 entitled "Electronic Discovery System" filed Mar. 27, 2009, and assigned to the assignee hereof and hereby expressly incorporated by reference herein.

FIELD

In general, embodiments of the invention relate to methods, systems and computer program products for electronic discovery and, more particularly, managing the collection of data from custodians in an enterprise.

BACKGROUND

Electronic discovery, commonly referred to as e-discovery or eDiscovery, refers to any process in which electronic data is sought, located, secured and searched with the intent of using it as evidence in a legal proceeding, an audit, a regulatory investigation, a forensics investigation or the like. E-discovery can be carried out offline on a particular computer or it can be accomplished in a network environment.

The nature of digital data makes it extremely well-suited for investigation. In particular, digital data can be electronically searched with ease, while paper documents must be scrutinized manually. Furthermore, it is difficult or impossible to completely destroy digital data, particularly if the data is stored in a network environment. This is because the data appears on multiple hard drives, and because digital files, even if deleted, generally can be undeleted. In fact, the only reliable means of destroying digital data is to physically destroy any and all hard drives where it is stored.

In the process of electronic discovery, data of all types can serve as evidence. This can include text, image, calendar event data, databases, spreadsheets, audio files, multimedia files, web sites and computer programs. Electronic mail (i.e., e-mail) can be an especially valuable source of evidence in civil or criminal litigation, because people are often less careful in these exchanges than in hard copy correspondence such as written memos or postal letters. Certain regulations and other business needs require email to be retained for years.

E-discovery is an evolving field that goes far beyond mere technology. It gives rise to multiple issues, many of which have yet to be resolved. For example, identifying data required to satisfy a given discovery request, locating the appropriate set of data that has been identified, and retrieving the data once it has been identified and located all pose problems in and of themselves. This is especially evident if the data that is being identified, located and retrieved comes from an evolving or disparate enterprise, such as a corporation that has experienced mergers, acquisitions, downsizing and the like. Mergers and acquisitions mean that the technology infrastructure across the enterprise may vary, at least in the interim. However, e-discovery must be able locate and

retrieve data from these disparate technology infrastructure in a timely fashion, sometimes within days of when the merger/acquisition occurs.

In addition to identifying, locating and retrieving digital data, the most critical part of any electronic discovery is the preservation of data, which involves maintaining an original source copy and storing it for preservation purposes or further processing. This too becomes a daunting task for the enterprise system that encompasses a myriad of different technology infrastructures and the like. Therefore, a need exists to improve the identification, location, retrieval and preservation processes, especially in instances in which the enterprise system includes disparate technology infrastructures and the like.

As previously noted, e-discovery, as opposed as conventional discovery of printed materials, provides for the ability to filter or search the data so as to reduce the volume of data to only that which is relevant to the request. Such searching is typically accomplished by determining a specific date range for the request, providing key words relevant to the case and the like. Searches using conceptual concepts, heuristics, linguistics and other variants are also becoming common. Still though, improvements in the area of searching are greatly in need to further add efficiency to the overall e-discovery process.

Once data has been retrieved, preserved and, in some instances, searched the electronic data may be reviewed by the requesting entity, such as a law firm, securities commission or the like. While large requests are generally suited for online review, the manner in which the data is presented for review adds efficiency to the review process and ultimately drives the cost of the review process. Therefore, improvements in the manner in which data is presented for review are also desirable as a means of increasing efficiency and reducing costs.

Lastly, once the digital data has been reviewed, data identified as relevant may need to be produced in a tangible format for further analysis or legal evidentiary purposes. The produced documents must be properly identified and include necessary redactions and confidentiality markings.

Until now, e-discovery management has been conducted on a case-by-case basis, meaning all tasking and workflow related to the e-discovery is based at the case level. Such management does not allow for finer granularity in the management of a case or for links to exist between different cases for the purpose of leveraging the e-discovery related to one case to another new or pre-existing case. Therefore, a need exists to improve the manner in which cases are managed and, in particular, how tasking and workflow are managed depending on case requirements and the like.

SUMMARY

Embodiments of the invention relate to systems, methods, and computer program products for electronic discovery and, in particular, improvements in electronic discovery that allow for electronic discovery to be efficiently and cost-effectively employed across a diverse enterprise.

A method for providing an electronic discovery system defines first embodiments of the invention. The method includes providing for a case management level within an electronic discovery system. The method further includes linking, by a computer processor device, a custodial management level to the case management level and linking, by a computer processor device, a data management level to the case management level and the custodial management level.

An electronic discovery system defines second embodiments of the invention, the system includes a computing platform including a memory and at least one processing device in communication with the memory. Additionally, the system includes an electronic discovery module stored in the memory, executable by the processor, including a case management level, a custodial management level linked to the case management level and a data management level linked to the case management level and the custodial management level.

A computer program product including a non-transitory computer-readable medium defines third embodiments. The computer-readable medium includes instructions for causing a computer to link a custodial management level to a case management level provided for within an electronic discovery system. Additionally, the computer-readable medium includes instructions for causing a computer to link a data management level to the case management level and the custodial management level.

BRIEF DESCRIPTION OF THE DRAWINGS

Having thus described embodiments of the invention in general terms, reference may now be made to the accompanying drawings:

FIG. 1 illustrates a network environment in which the processes described herein are implemented, according to one embodiment of the invention;

FIG. 2 is a block diagram of an electronic discovery manager server, in accordance with embodiment of the present invention;

FIG. 3 is a block diagram of a database server, in accordance with an embodiment of the present invention;

FIG. 4 is a block diagram of a collection server, in accordance with an embodiment of the present invention;

FIG. 5 is block diagram illustrating electronic discovery management structure, in accordance with an embodiment of the invention;

FIG. 6 is a flow diagram of a method for initiating a case or matter including creating search terms, creating and sending preservation notices, sending reminder notices and creating and sending surveys to custodians, in accordance with embodiments of the present invention;

FIG. 7 is a flow diagram of a method for custodian management in an electronic discovery system, in accordance with an embodiment of the present invention;

FIGS. 8 and 9 are flow diagrams of methods for harvesting different data types in an electronic discovery system; in accordance with an embodiment of the present invention; and

FIGS. 10 through 14 are illustrations of exemplary user interfaces visible to a user conducting electronic discovery by means of an electronic discovery system in accordance with one embodiment of the present invention.

DETAILED DESCRIPTION OF EMBODIMENTS OF THE INVENTION

Embodiments of the present invention now may be described more fully hereinafter with reference to the accompanying drawings, in which some, but not all, embodiments of the invention are shown. Indeed, the invention may be embodied in many different forms and should not be construed as limited to the embodiments set forth herein; rather, these embodiments are provided so that this disclosure may satisfy applicable legal requirements. Like numbers refer to like elements throughout.

As may be appreciated by one of skill in the art, the present invention may be embodied as a method, system, computer program product, or a combination of the foregoing. Accordingly, the present invention may take the form of an entirely software embodiment (including firmware, resident software, micro-code, etc.) or an embodiment combining software and hardware aspects that may generally be referred to herein as a "system." Furthermore, embodiments of the present invention may take the form of a computer program product on a computer-readable medium having computer-usable program code embodied in the medium.

Any suitable computer-readable medium may be utilized. The computer-readable medium may be, for example but not limited to, an electronic, magnetic, optical, electromagnetic, infrared, or semiconductor system, apparatus, device, or propagation medium. More specific examples of the computer readable medium include, but are not limited to, the following: an electrical connection having one or more wires; a tangible storage medium such as a portable computer diskette, a hard disk, a random access memory (RAM), a read-only memory (ROM), an erasable programmable read-only memory (EPROM or Flash memory), a compact disc read-only memory (CD-ROM), or other optical or magnetic storage device; or transmission media such as those supporting the Internet, an intranet, or a wireless network. Note that the computer-readable medium could even be paper or another suitable medium upon which the program is printed, as the program can be electronically captured, via, for instance, optical scanning of the paper or other medium, then compiled, interpreted, or otherwise processed in a suitable manner, if necessary, and then stored in a computer memory.

Computer program code for carrying out operations of embodiments of the present invention may be written in an object oriented, scripted or unscripted programming language such as Java, Perl, Smalltalk, C++, or the like. However, the computer program code for carrying out operations of embodiments of the present invention may also be written in conventional procedural programming languages, such as the "C" programming language or similar programming languages.

Embodiments of the present invention are described below with reference to flowchart illustrations and/or block diagrams of methods, apparatus (systems), and computer program products. It may be understood that each block of the flowchart illustrations and/or block diagrams, and/or combinations of blocks in the flowchart illustrations and/or block diagrams, can be implemented by computer program instructions. These computer program instructions may be provided to a processor of a general purpose computer, special purpose computer, or other programmable data processing apparatus to produce a machine, such that the instructions, which execute via the processor of the computer or other programmable data processing apparatus, create mechanisms for implementing the functions/acts specified in the flowchart and/or block diagram block or blocks.

These computer program instructions may also be stored in a computer-readable memory that can direct a computer or other programmable data processing apparatus to function in a particular manner, such that the instructions stored in the computer readable memory produce an article of manufacture including instruction means which implement the function/act specified in the flowchart and/or block diagram block(s).

The computer program instructions may also be loaded onto a computer or other programmable data processing apparatus to cause a series of operational steps to be performed on the computer or other programmable apparatus to

5

produce a computer-implemented process such that the instructions which execute on the computer or other programmable apparatus provide steps for implementing the functions/acts specified in the flowchart and/or block diagram block(s). Alternatively, computer program implemented steps or acts may be combined with operator or human implemented steps or acts in order to carry out an embodiment of the invention.

Embodiments of the present invention provide a unique electronic discovery system that allows for the management of cases, custodians, and data separately, which advantageously causes the processes implemented by and through the system to be significantly more efficient and scalable than those of the prior art. First, the three major elements of the organizational structure of the system (cases, custodians, and data) should be explained. There are countless circumstances that may arise within an enterprise or business that require the collection of electronic data from the employees and officers of the enterprise or business. Such circumstances may arise out of ongoing litigation, investigations, regulatory compliance issues, etc. Each time electronic data is required or is potentially required to be collected, the subject matter of the reason for the collection is a "matter," and, eventually, a "case" within the electronic discovery system of the present invention. Within each case, the electronic data that is required will generally have been created by or associated with a particular employee or officer, i.e. a "custodian." Each member of the enterprise or business could be a custodian. Finally, the custodian data that is harvested or collected from various storage locations needs to be available to be readily accessed by those who need it for the case. In some instances, a particular custodian may not be the target of a particular collection, but rather an "entity" such as a shared drive or other shared network storage location. Thus, there are matters/cases (which will be referred to together as "cases" for convenience), custodians, and data which all need to be identified, established, and managed within the electronic discovery system in order to complete the data collection processes. Cases, custodians, and collected data form the three fundamental units of work of the present electronic discovery system.

Existing electronic discovery systems have generally been structured so that every process and piece of data relating to a collection is stored and managed according to one governing organizational header, such as a particular litigation or a particular collection. In other words, individuals identified for collection as well as the data collected from such individuals are assigned to a collection or the particular case, matter, litigation, investigation, etc. for which the collection was required, and all management activities are performed by working through the organizational hierarchy of that case. Embodiments of the present invention, on the other hand, capitalize on the separate storage of case records, custodian records, and collected data within an electronic discovery system. This novel innovation, combined with strategic linkages between the different storage areas arising out of the relationships between cases, custodians, and data, allows management of the e-discovery system to be implemented in a unique and extremely efficient manner that is a significant improvement over existing systems.

FIG. 1 illustrates an exemplary electronic discovery system 100 in accordance with an embodiment of the invention. In some embodiments, the environment of the electronic discovery system 100 is the information technology platform of an enterprise, for example a national or multi-national corporation, and includes a multitude of servers, machines, and network storage devices in communication with one another

6

over a communication network. In particular, an electronic discovery management server 110, at least one database server 120, a collections server 130, enterprise personal computers 140, enterprise file servers 150, including at least one personal network storage area and at least one shared network storage area, enterprise email servers 160, a conversion services server 170, a short-term staging drive 180, and a long-term network storage network 190 are all in communication over a communication network 102. The communication network 102 may be a wide area network, including the Internet, a local area network or intranet, a wireless network, or the like.

As shown in the block diagram of FIG. 2, the electronic discovery management server 110 provides user interface management for a user via user interface 118. In some embodiments, the electronic discovery management server 110 is a web server that can be accessed via a web browser. In one particular embodiment, the electronic discovery management server 110 is an intranet website server that may be accessed utilizing a web browser on a machine within the enterprise. Through the electronic discovery management server 110, the user interface 118 may be presented to a user for the purposes of managing the electronic discovery process and all processes described herein that are inherent thereto. For illustrative purposes, it may be assumed herein that the primary user interacting with the user interface 118 is an employee or contractor of the company who serves an electronic discovery management role, and hereafter is referred to as the "e-discovery manager." As discussed in greater detail below, the e-discovery manager may utilize the user interface 118 to manage cases, custodians, collections, and collected data. It should be appreciated, however, that any individual could use the user interface 118 to perform the manual functions herein attributed to the e-discovery manager, and, indeed, that an automated process could perform those functions as well.

Referring again to FIG. 1, the electronic discovery management server 110 is in communication with the database server 120 and the collections server 130 via the communication network 102. The collection server 130 may be configured to run an application configured to manage network collection of electronic data associated with custodians residing on the network. The database server 120, as shown in the block diagram of FIG. 3, is configured to provide database services for the electronic discovery management server 110, including housing the Unified Directory/custodian database 122, which includes data relating to individual custodians, the case database 124, which includes data relating to particular cases, and ongoing collections database 126, which includes data relating to collections being undertaken by the collections server 130. Each of the foregoing databases within the database server 120 is discussed in detail below. It should be understood that multiple database servers could be employed instead of a single database server, and reference to a single database server is for illustrative and convenience purposes only. For example, the Unified Directory 122 could be stored in one database server, the case database 124 could be stored in another database server, and the ongoing collections data 126 could be stored in yet another database server.

Regardless of the number of database servers employed, it is an object of embodiments of the present invention that data relating to custodians and data relating to cases be stored in the database server 120 independently such that custodians and cases may be managed separately. While custodian data in the Unified Directory 122 and case data in the case database 124 may be linked or correlated within the database server 120, by allowing the data to be stored and managed separately

in the database server **120**, embodiments of the present invention advantageously foster greater efficiency in the management processes of an enterprise electronic discovery environment. For example, in an environment where custodians may be assigned to multiple cases, the effort associated with the collection of data from custodians is greatly reduced because the data relating to the custodian's storage locations does not need to be generated on a case-by-case basis or reproduced in each case record and because, in some situations, data may only be collected once from a particular custodian but used in multiple cases.

It should be understood that, as used herein, the terms "linking" and "correlating" mean associating one set or item of data stored in a first storage location with another set or item of data stored in a second storage location. For example, linking or correlating a case record to a custodian profile means associating the case data stored in a particular location with the custodian data stored in a different location. Likewise, linking or correlating a harvested data set to a case record means associating the harvested data set stored in particular location with the case data stored in a different location. The first and second storage locations may be in the same datastore or in different datastores and may be in different physical geographic locations.

When a case is initialized and a custodian is assigned to the case (because the custodian was identified as a subject for electronic discovery), information for that custodian such as network identifications, human resources information, and other data relating to data storage locations, is accessed by the electronic discovery management server **110** in the Unified Directory **122** in the database server **120** and linked to the particular case record in the case directory **124**, rather than manually input by the e-discovery manager into the case. Thus, in the event the same custodian will be the subject of an electronic discovery request in multiple cases, and therefore will be assigned to multiple cases, by having the data relating to that custodian stored in a separate storage location, i.e. the Unified Directory **122**, and linked to the multiple case records in the case directory **124**, the e-discovery manager avoids having to re-generate and re-enter identical information about the same custodian into multiple case records.

Furthermore, in addition to allowing for management of custodians apart from cases, embodiments of the present invention also provide for management of collected data apart from cases. In this regard, in certain embodiments, the data collected from a particular custodian is stored separately from both the custodian information and any relevant case information (as discussed below, the collected data is stored in long-term storage area network **190**), but is linked to a custodian, which is in turn linked to one or more cases. This is advantageous because in the event a particular custodian is assigned to multiple cases, data collected from the custodian may be shared with the other case(s) to which the custodian is assigned, which reduces the likelihood of the inefficiencies associated with over-collection. The foregoing are only two examples of the advantages brought about by the unique structure of the present invention; indeed, the separation of cases, custodians and collected data such that they may be linked together yet managed separately greatly improves the efficiency of countless processes crucial to the operation of an electronic discovery system within the environment of an enterprise or any environment with multiple custodians and multiple cases.

Thus, the various processes and components of the electronic discovery system **100** may be primarily categorized within one of case management, custodian management, or data management, although there are necessarily links

between the various datastores (case, custodian, collected data) to streamline each process and ensure that each case record is complete. The particular processes and components that may be incorporated into embodiments of the present invention will now be fully explained within the context of the particular unit of work within which they primarily fall, whether it is custodian management, case management, or data management.

Custodian Management

With regard to custodian management, according to some embodiments of the present invention, the Unified Directory/custodian database **122** houses information relating to all potential custodians within the enterprise and the locations where those custodians store data. The information stored in the Unified Directory **122** may include for a particular custodian, for example, the custodian's name, position, human resources identifier (a unique number for each employee of the enterprise), employment location, domain, email addresses, network user identification, personal computer(s) name, paths of network storage devices used by the custodian, including Shared Drives and HomeSpaces, work history, related persons (such as managers, team members or subordinates), and any other information that may be relevant to the discovery process. Since the human resources identifier (perhaps a social security number) is always unique for each custodian, in some embodiments, the Unified Directory **122** may be organized around the human resources identifier. The Unified Directory **122** is generated through a multi-step process that utilizes multiple tools and methods of identifying relevant information relating to custodians and the locations in which they store data.

For example, the electronic discovery management server **110** or the database server **120** may be configured to interface with the computer databases of the human resources computer systems of the enterprise to copy the information from the human resources databases into the Unified Directory **122**. In some embodiments, the electronic discovery management server **110** may also reach out to a network directory, such as Windows Active Directory, to identify network resources related to particular custodians and integrate this information into the custodian entries including the copied human resources information. Information for the Unified Directory **122** may also be obtained from the managers of the information technology network, i.e., those individuals responsible for setting up email accounts for custodians and managing the various file servers of the enterprise. Furthermore, in addition to retrieving information in the manners described above, in some embodiments, information in the Unified Directory **122** is generated through tools initialized and/or deployed by the electronic discovery management server **110**. In particular, in some embodiments, as shown in FIG. 1, a profile scanning tool **112**, and a mapping tool **114** are provided.

The profile scanning tool **112** may be deployed by the electronic discovery management server **110** and is configured to crawl the communication network **102**, scan each of the enterprise personal computers **140**, and transmit to the database server **120** identifying information about each computer, such as computer name and IP address, and a list of all profiles, including demographics information, (or network user identification) associated with each computer. According to different embodiments, the profile scanning tool **112** may be run on the electronic discovery management server **110**, the collection server **130**, or another server in the communication network **102**. In some embodiments, the profile

scanning tool **112** is further configured to identify and transmit to the database server **120** the most recent date and time at which a particular profile was logged on to the machine. According to some embodiments, when information relating to a particular computer is received by the database server **120**, the database server **120** uses the profile information, which may include several user identifications, to associate the particular computer to the custodians in the Unified Directory **122** who are assigned those user identifications and store the computer names and IP addresses in those custodians' entries in the Unified Directory for future reference in collections. The database server **120** may also record in each custodian's entry in the Unified Directory **122** the last time the computer was accessed by the custodian, according to the profile information transmitted by the profile scanning tool **112**. In other embodiments, the list obtained by the profile scanning tool **112** may be stored separately from the Unified Directory **122** and accessed only when a particular collection is being undertaken. Thus, the profile scanning tool **112** ultimately generates a list of personal computers used by each custodian, which list may be utilized to populate the custodian entries in the Unified Directory **122**, or may be a separate directory to be utilized at the time of collection, or may be stored elsewhere, as long as it is readily accessible to the e-discovery manager when a collection of a custodian's local machine(s) is initialized, as discussed in detail below.

In accordance with some embodiments of the invention, the mapping tool **114** is configured to crawl the communication network **102** and examine the enterprise file servers **150** residing on the communication network **102** to locate and identify the path of any personal network storage area on each server. As used herein, a personal network storage area is a network storage area associated with a single user who reads data from or writes data to it. Personal network storage areas may be in the form of network storage devices or folders or other resources within a network storage device and may be referred to hereafter for clarity purposes as "HomeSpaces." According to different embodiments, the mapping tool **114** may be run on the electronic discovery management server **110**, the collection server **130**, or another server in the communication network **102**. In some embodiments, the mapping tool **114** is a Windows service that is scheduled to execute through use of Windows Scheduled Task. As the mapping tool **114** crawls the communication network **102**, it is configured to examine each file server and transmit to the database server **120** the path of any network storage area within the plurality of servers **134** that it positively identifies as a HomeSpace. In some embodiments, the mapping tool **114** is configured to explore the enterprise file servers **150** by obtaining and reviewing the directories on each server and evaluating the paths of each network storage area therein, including folders and other storage devices and resources.

With regard to identifying a particular network storage area as a HomeSpace, according to some embodiments, the mapping tool **114** is configured to utilize conventional naming techniques for paths in the communication network **102** to identify those paths of network storage areas within the enterprise file servers **150** that include an indicator, based on the conventional naming techniques, that the particular storage areas associated with those paths are accessed and used by only one user, and are therefore HomeSpaces. In accordance with some embodiments of the invention, each user of the communication network **102** is assigned to at least one user identification and those user identifications are the indicators that the mapping tool **114** attempts to locate within paths when identifying HomeSpaces. In such embodiments, it is the convention that the paths of HomeSpaces on the communi-

cation network **102** include the user's user identification. On the other hand, paths of shared network storage areas do not include user identifications. Therefore, the mapping tool **114** may explore the directories of each server within the plurality of servers, evaluate each path in turn, and make a determination as to whether or not the path includes a user identification.

If it is determined that the path includes the designated indicator, for example, a user identification, the mapping tool **114** is configured to positively identify the particular network storage area identified by that path as a HomeSpace and transmit to the database server **120** the particular user identification and the path of the HomeSpace. When that information is received by the database server **120**, the database server **120** uses the user identification to link the particular HomeSpace to the custodian in the Unified Directory **122** associated with that user identification. Indeed, the HomeSpaces identified through the mapping tool **114** could be added to the relevant custodian entries in the Unified Directory **122**, making them accessible to the e-Discovery manager each time those custodians are added to new cases. In other embodiments, the HomeSpace directory generated by the mapping tool **114** may be stored separately and only utilized or accessed when a particular collection is undertaken. In yet other embodiments, it could be linked to the Unified Directory **122**.

In some embodiments, the mapping tool **114** is also configured to recognize and transmit, and the database server **120** is configured to house, an indication of the last time the HomeSpace was accessed by the particular user, for example, the last time any data was read from and/or written to the HomeSpace. Additionally, in some embodiments, the mapping tool **114** is configured to recognize when multiple paths map to the same network storage area. The collection server **130** compares paths for the same user to determine if duplicative entries exist. This advantageously enables avoidance of multiple collections of the same data. Thus, the profile scanning tool **112** ultimately generates a list of HomeSpaces used by each custodian, and this list may be presented to the e-discovery manager when a collection of a custodian's HomeSpaces is initialized, as discussed in detail below.

In addition to storing a list of personal computers and HomeSpaces used by a particular custodian, which lists were generated by the profile scanning tool **112** and the mapping tool **114** respectively, in accordance with some embodiments of the present invention, the database server **120** is also configured to store a list of any shared network storage areas used by the custodian. As used herein, a shared network storage area is a network storage area associated with multiple users who read data from and/or write data to it. Shared network storage areas may also be in the form of network storage devices or folders or other resources within network storage devices and may be referred to hereafter for clarity purposes as "Shared Drives." The user interface **118** is configured to receive a path of a Shared Drive input by the e-discovery manager and store the path in the Unified Directory **122** in relation to one or more custodians' human resources identifier(s). More particularly, in some embodiments, once a particular user of the communication network **102** is chosen for the collection process, the e-discovery manager may undertake to identify the particular shared network resources that that individual is using, and eventually, the paths associated with those shared network resources. This may be accomplished through conversations with the particular individual, by utilizing data returned from the local collection tool **132** executed on collection server **130** (shown in the block diagram of FIG. 4) deployed to the particular user's machine (as

11

discussed in detail below), and/or by utilizing a file browsing tool **116** executed on electronic discovery manager server **110** (as shown in FIG. 2).

According to some embodiments of the present invention, the file browsing tool **116** is configured to be utilized by the e-discovery manager through the user interface **118**. The file browsing tool **116** gives the e-discovery manager elevated authority within the communication network **102** to access, in a limited manner, the enterprise file servers **150** within the communication network **102**. While the file browsing tool **116** may not allow access to the actual files stored on certain file servers, it allows the e-discovery manager to browse through the directories of the file servers **150**, locate files that have been accessed by the custodian, and determine the size of the files. In accordance with some embodiments, the e-discovery manager may initially have a general idea of a particular file server within the enterprise file servers **150** that the custodian has used in the past. For example, the custodian may communicate to the e-discovery manager a particular folder name and/or drive name on which he/she has stored files. Additionally, in some embodiments, the e-discovery manager may have already undertaken a local collection process on the custodian's machine, wherein the local collection tool **132** returned a list of the network resources that the user of that machine has used. In that event, the e-discovery manager may be aware of the particular drive referenced by the user. The e-discovery manager may then employ the file browsing tool **116** to browse out to the particular drive mentioned, scan the folders for any folder having a name resembling that name given by the user, identify any particular files created by and/or accessed by the user, determine the size of such files, and retrieve the path of any folder (or Shared Drive) including data belonging to the user.

The retrieved paths of the Shared Drives may then be added, either manually or automatically, to the Unified Directory **122** in the database server **120**. Thus, the Unified Directory **122** may store in connection with one custodian (and in particular in relation to the custodian's human resources identifier) a list of the personal computers, HomeSpaces, and Shared Drives associated with that custodian. Each of these locations is a potential source of data stored by the custodian, and once an investigation or collection of a custodian is initiated, the location information stored in the Unified Directory **122** may be accessed to determine the particular storage locations that need to be addressed during the investigation/collection. In other embodiments, the paths of the Shared Drives are not added to the Unified Directory **122** but merely stored in the case record **124** of one or more of the case(s) on which the custodian has been added to be accessed later when collections are initialized for the case. Therefore, according to some embodiments, the location storage information for a particular custodian is generated and stored either in the custodian's entry in the Unified Directory **122** or in another location where it is linked to the entry or otherwise readily accessible when accessing the custodian entry. Once the custodian is assigned to a particular case, the information may be automatically accessed through the Unified Directory **122** (as the custodian entry in the Unified Directory **122** is linked to the case record **124**) and used to initiate collection of the custodian's files. This is advantageous and extremely efficient as it allows a completely automated investigation/collection process, rather than relying on the e-discovery manager to manually input the targeted machines and file servers at the time of collection.

It should be noted that the Unified Directory **122** may be regularly or continuously updated as new information is gathered using the tools described herein. More particularly, the

12

electronic discovery management server **110** may be configured to automatically retrieve data from the human resources databases and Active Directory and any other relevant sources, such as information technology directories or lists, as well as deploy the profile scanning tool **112** and the mapping tool **114**, at regularly scheduled intervals. Alternatively, rather than periodically retrieving data from the various data sources such as the human resources databases, the system **100** may be configured such that the database server **120** is continuously interfacing with the data sources such that the Unified Directory **122** is updated in real-time as the data within the data sources change. In either instance, each of the feeds of information into the Unified Directory **122** is regularly updated to ensure that the data in the Unified Directory **122** is current.

In some embodiments, the database server **120** is configured such that all historical data relating to a custodian is stored in relation to that custodian's human resources identifier in the Unified Directory **122**. Thus, when the feeds of information into the Unified Directory **122** are updated, in the event data relating to the custodian has changed, the database server **120** is configured to store in the Unified Directory **122** the new data and any relevant metadata, including, for example, the time and date of the change, as well as maintain a record of the old data so that it is still a part of the custodian's profile in the Unified Directory **122**. For example, in the event the profile scanning tool **114** identifies a new personal computer associated with a custodian and one of the personal computers associated with the custodian previously is no longer identified, the database server **120** is configured to store in the Unified Directory **122** the information for each computer, as well as indications as to when the new computer was first identified and when the old computer was no longer identified. In this way, the custodian profile within the Unified Database **122** may include a history of the personal computers used by the custodian. Such information may be relevant at the time of investigation or collection of the custodian.

One feed of information into the Unified Directory **122** which is particularly relevant to electronic discovery is employment status. According to some embodiments, when the feed of information from the human resources databases to the Unified Directory **122** includes a change as to employment status of a particular custodian, the electronic discovery management server **110** is configured to recognize the change and possibly perform particular functions in response. More specifically, in the event it is recorded in the Unified Directory **122** that the employment status of a particular custodian changes from active to terminated, the electronic discovery management server **110** is configured to determine whether the custodian is assigned to any case or matter, and, if so, to transmit to the designated manager or contact for the case or matter an electronic communication notifying the manager of the terminated status and inquiring as to whether the manager would like the terminated custodian's data collected. In the event the manager responds in the affirmative, the electronic discovery management server **110** is configured to automatically initiate the various collection processes of the present invention. Therefore, the custodian's data may be advantageously collected prior to any destruction or unavailability that could be caused by the termination. Alternatively, in other embodiments, the electronic discovery management server **110** may not communicate with the manager and may automatically initiate collection upon recognizing a change in employment status.

Case Management

With regard to case management processes, according to some embodiments, a case may be initialized by the e-dis-

13

covery manager utilizing the user interface 118. In this regard, the e-discovery manager may enter into the user interface 118 certain information about a particular matter or case, such as a case name and/or number, a short description of the matter/case, a legal identifier, the particular requester (i.e., who asked for the case to be opened), managers or contacts for the matter (i.e., individuals involved in the substance of the matter rather than the process, like the e-discovery manager), custodians, etc. The electronic discovery management server 110 is configured to store this information in the case database 124 in the database server 120. The case database 124 is configured to house this information such that all information relating to a particular matter or case is related within the case database 124 and a user can use the user interface 118 to view a profile of the matter or case including all the information.

Once the matter and/or case has been initialized, the e-discovery manager may add custodians to the matter or case from whom data may be required to be collected. In some embodiments, the electronic discovery management server 110 is configured to add numerous custodians to a single matter or case at one time. In this regard, the e-discovery manager may use the user interface 118 to enter in identifying information about the custodians. The identifying information for each custodian does not have to be of the same type. For example, a name may be entered for one custodian, an email address for another, a network user identification for another, and a human resources identifier for another. The user interface 118 is configured to receive the identifying information in different input areas depending upon the type of identifying information being received. The electronic discovery management server 110 is configured to use the input information to search the Unified Directory 122 in the database server 120 to determine which custodians are associated with the input information. In the case of a human resources identifier being entered, only one custodian in the Unified Directory 122 may be a match. On the other hand, in the case of a name being entered, multiple records may be returned with explanatory details, thus enabling the e-discovery manager to select the appropriate match based on the additional details provided.

The electronic discovery management server 110, after searching the Unified Directory 122 with the input identifying information, is configured to present through the user interface 118 a list of all custodians matching the input identifying information. In the event only one match was returned for a particular set of input identifying information, the electronic discovery management server 110 is configured to automatically select the custodian to be added to the case or matter. On the other hand, in the event more than one match was located for a particular set of input identifying information, then the multiple matches may be presented together to the e-discovery manager through the user interface 118 and marked so that the e-discovery manager must review the multiple custodian profiles associated with the matches to determine the correct custodian that should be added to the case or matter. In doing so, the e-discovery manager may consider the other information in the profiles, such as corporate title, work location, associated custodians, etc. Such information can inform the e-discovery manager as to whether the located custodian is the one intended. The e-discovery manager may then select the correct custodian for addition to the case or matter and confirm that all custodians selected may be added to the case or matter.

According to some embodiments, "adding" a custodian to a case or matter involves linking the custodian profile in the Unified Directory 122 to the case or matter in the case database 124. More specifically, the electronic discovery manage-

14

ment server 110 is configured to, once a particular custodian is identified to be added to a particular case, enter into the custodian section of the relevant case record within the case database 124 an identification of the custodian, i.e. the custodian's name, and a link to the custodian's profile in the Unified Directory. According to other embodiments, the custodian's profile information is retrieved and copied into the case record by the electronic discovery management server 110. In either instance, when a collection for a particular custodian is initiated in a particular case by the e-discovery manager, the electronic discovery management server 110 will automatically access the custodian profile for the custodian and determine the particular data storage locations that apply to that custodian. Thus, as will be discussed in detail below, in situations in which the custodian has already been added to the case and matter, the e-discovery manager must only select the particular custodian for collection, and the remaining collection process will be automated, because the Unified Directory 122 already houses all of the relevant information to access the custodian's data and the electronic discovery management server 110 is configured to automatically implement the various collection tools. This is a highly advantageous improvement over the systems of the prior art.

According to some embodiments, upon adding custodians to a matter, the electronic discovery management server 110 is configured to initiate the transmission of preservation notices and surveys to the custodians. In this regard, preservation notices and surveys relevant to the particular case or matter are stored in or linked to the case profile in the case database 124. Transmission of the preservation notices and surveys to custodians added to the case may be automated, for example, there may be preset instructions within the case profile that cause the electronic discovery management server 110 to transmit a particular preservation notice and survey at a particular date or time or upon a particular triggering event, such as a custodian being added to the case, or the e-discovery manager may manually cause the preservation notices and surveys to be transmitted. In some embodiments, the electronic discovery management server 110 is configured to transmit the preservation notices and surveys via a standard email function. The surveys may be tied to the preservation notices such that they are transmitted to custodians together, and one survey may be tied to more than one preservation notice. When a custodian responds to a survey, the survey response is received by the electronic discovery management server 110 and stored in relation to the relevant custodian in the case profile in the case database 124. In other embodiments, the architecture of the case database 124 may be configured such that it flexibly enables a user to link any/all preservation notice(s) and/or survey responses from a particular custodian to that custodian, regardless of the particular case to which the preservation notice and/or survey response relates. Furthermore, the electronic discovery management server 110 may be configured to store all or a portion of the data received in the survey response in the Unified Directory 122 in the custodian's profile.

According to some embodiments, each transmission of a preservation notice and survey to a custodian, and each corresponding response, is tracked in the relevant case profile in the case database 124. The electronic discovery management server 110 may also be configured to transmit reminder notices if responses to the surveys are not received within a predefined period of time. The electronic discovery management server 110 may also be configured to schedule reminder notices to be sent to custodians to periodically refresh the custodians' memory of their duty to preserve files/documents pertaining to the matter. In some embodiments, there is a

15

“legal hold portal” in which the custodian is presented with a single view of all outstanding legal holds applicable to the custodian. In this legal hold portal, the custodian is presented with a comprehensive view of all outstanding notices and obligations to preserve data. If the custodian has somehow failed to acknowledge compliance with the legal hold, the legal hold portal will also provide that information to the custodian, thus providing an advantageous method of securing affirmation from the custodian. According to some embodiments, the reminder notices may be inactivated upon closure or termination of a case or matter, but can then be reactivated by the e-discovery manager. In some embodiments, once a preservation notice has been sent to a custodian, the electronic discovery management server **110** may undertake to prevent any reimaging or refreshing of the custodian’s personal computer(s) by transmitting an alert of the preservation notice to the enterprise’s information technology management group. In addition, the survey responses received from custodians serve to inform the collection process. For example, one survey may inquire as to what network storage devices the custodian uses when storing data. The answer that the custodian gives to the survey may inform the addition of Shared Drives to the custodian profile in the Unified Database **122** that may be used later in collection.

According to some embodiments of the present invention, the e-discovery manager may utilize the user interface **118** to add attachments, notes, tasks, and search terms to a case or matter. In some embodiments, the contacts/managers for a case may also access the case profile in the case database **124** using a web browser and may add attachments, notes, tasks, and search terms to be stored therein. Thus, the e-discovery manager may not be the only entity with access to the case and case management tools of the electronic discovery management server **110**. The subject matter of the attachments, notes and tasks could be anything relevant to the case or matter. In some embodiments, the tasks are directed to the e-discovery manager or case manager or collector. In other embodiments, the tasks are tasks that particular custodians must complete and the electronic discovery management server **110** is configured to transmit a notice to the custodians that the task needs to be completed, perhaps using standard email functions. With regard to attachments, the e-discovery manager, or the contact/manager of the case, may upload relevant files to be attached to the case profile.

With regard to the search terms, the e-discovery manager or the case contacts or managers may add certain terms to the case profile to be applied when searching the collected data to locate data responsive or relevant to the underlying issues in the case. Storing the search terms within the case profile is advantageous as it creates a record of the searching that is to be undertaken with respect to the data and aids in organization of the data, as discussed further below.

According to some embodiments of the present invention, when a decision is made that it is time to collect from certain custodians in a matter, the e-discovery manager may use the user interface **118** to release the custodians from the matter to the underlying case. This release triggers the commencement of collection of the custodians’ data using the various tools of the system and the data storage information housed in the custodians’ entries in the Unified Directory **122** and linked to the case record **124**. Furthermore, as discussed briefly above and in detail below, from release of the custodians (i.e. selection of those custodians in the matter to be released to the case by the e-discovery manager) to collection and storage of the collected data, the process may be entirely automated. In some embodiments, the electronic discovery management server **110** is configured to allow all custodians assigned to

16

the matter to be released to the case at the same time. In addition, in instances where the e-discovery manager has previously created groups of custodians within the case, the electronic discovery management server **110** is configured to allow a group of custodians to be released from a matter to a case at the same time. In some embodiments, automated collection of the custodian’s data can occur at the time the custodian is released from the matter to the case, thus minimizing the risk of spoliation.

Data Management

Once a custodian has been identified for collection, whether manually by the e-discovery manager or by being released from a matter to a case, the electronic discovery system **100** is configured to automatically collect the custodian’s data using the location information stored in the Unified Directory **122**. Therefore, the electronic discovery management server **110** accesses the custodian profile of the custodian to be collected in the Unified Directory **122** and determines, from the information stored therein, the different locations of data storage for the particular custodian that must be collected. There are many different locations that the system **100** can address, including personal computers, email accounts, and network storage areas, including HomeSpaces and Shared Drives.

If a custodian profile (for a custodian released for collection) includes at least one personal computer(s) associated with the custodian, then the electronic discovery management server **110** may undertake to collect the files on these machines. Therefore, the electronic discovery management server **110** may retrieve the relevant machine identifying information, such as domain, name, IP address, etc., and may initialize deployment of a local collection tool **132** running on collections server **130** (as shown in FIG. 4).

The local collection tool **132** is configured to be deployed from the collections server **130**, whether through an application running on the collections server **130** or otherwise, or another server within the network **102** to any of the enterprise personal computers **140**. Therefore, for a particular custodian, the local collection tool **132** is configured to utilize the machine identifying information supplied by the electronic discovery management server **110** to be deployed to the identified custodian computer. According to one embodiment, the local collection tool **132** is configured to be automatically installed on the target custodian’s personal computer. The local collection tool **132** is further configured to generate a snapshot of the data residing on the local storage of the personal computer **140**, for example, by using a commercially available tool such as the Volume Shadow Copy Service, store the snapshot in a storage area on the personal computer, and transmit copies of the files included in the snapshot to the collections server **130**. By transmitting the data from the snapshot of the data stored on the hard drive of the personal computer, the local collection tool **132** advantageously allows the custodian to continue to use her machine without substantial interference from the local collection tool **132** and even interact with the data stored on the hard drive as the snapshot of the data is being transmitted to the collections server **130**. In some embodiments of the invention, the tool may be deployed to the users’ computer and harvest all relevant files without the users’ knowledge, and with no noticeable performance degradation to the users’ machines. This is advantageous when attempting to collect data from a user that may be under investigation for alleged wrongdoing, for example.

17

In addition to the functions described above, the local collection tool **132** may also be configured to transmit to the database server **120** a catalog of the files included in the snapshot to be stored in the ongoing collections database. This catalog may be referenced by the collections server **130** in order to determine whether collection is complete and to resume interrupted collections at the point of interruption. Additionally, in accordance with some embodiments, the local collection tool **132** is configured to compile and transmit to the electronic discovery management server **110** a list of network resources the user is using, including, for example, network applications and file servers that the user has used, accessed, or mapped as network drives. This list of resources may be stored in the database server **120** in the custodian's profile in the Unified Directory **122**. With regard to transmission of the files themselves, according to one embodiment of the invention, the local collection tool **132** is configured to compress, hash, and upload the files included in the snapshot to the collections server **130**.

In some embodiments, the electronic discovery management server **110** may utilize a computer watching tool **117** to determine when to attempt a collection from a custodian's machine. The computer watching tool **117** is configured to monitor the network **102** and determine which of the enterprise personal computers **140** are online. Therefore, in the event there is a custodian whose local machine needs to be collected, the computer watching tool **117** is configured to determine when that machine joins the network **102** (i.e., when it appears to the computer watching tool **117**) and inform the electronic discovery management server **110** that it should initialize the local collection tool **132** immediately.

If a custodian profile (for a custodian released for collection) includes any paths for HomeSpaces or Shared Drives, then the electronic discovery management server **110** may undertake to collect the files from these file servers by initializing the file server collection tool **134** running on collection server **130** (as shown in FIG. 4). The file server collection tool **134** is configured to access the file server located at the given path, whether the file server is a HomeSpace or a Shared Drive, copy the data residing on the file server, and compress, hash, and transmit the copied data to the collections server **130**. The file server collection tool **134** may be programmed with preset instructions that allow it to only copy files meeting certain criteria, for example, files that have certain file extensions. Alternatively, the programmed instructions may prevent the file server collection tool **134** from copying files having certain file extensions or other attributes. Either of the foregoing is advantageous if the e-discovery manager is not interested in copying executable files or source code, for example. In some embodiments, the file server collection tool **134** is also configured to generate a size estimate of the files residing on the targeted file server. In one embodiment, the file server collection tool **134** may automatically begin the collection process (copying and transmitting data) if the size estimate falls below a predetermined threshold. In addition, in some embodiments, the file server collection tool **134** is configured to determine whether a particular folder that it is collecting from a file server includes more than a token amount of nearline files, and, in the event that the folder does include such nearline files, choose to not collect such files so as to avoid overloading the server. Therefore, according to different embodiments, the file server collection tool **134** copies all or a portion of the files residing on a file server located at the path given in the released custodian's profile and transmits them to the collections server **130**.

If a custodian profile (for a custodian released for collection) includes an email address for an email account on the

18

enterprise email server **160**, then the electronic discovery management server **110** may undertake to collect the files from the enterprise email server **160** by initializing the active email collection tool **136** running on collections server **130** (as shown in FIG. 4). In some embodiments, the active email collection tool **136** is configured to access the particular Microsoft Exchange server within the enterprise email server **160** on which the custodian's account resides (which is known based on the information included in the Unified Directory **122**), copy all email located there, including emails deleted by the custodian up to a predetermined period of time prior to the collection, (for example, seven days prior to the collection) and transmit the copied emails to the collections server **130**.

Regardless of the storage resource location from which data is being collected, or the particular type of data being collected, the collections server **130** is configured to store the data first (while the collection is still ongoing) in the short-term staging drive **180** until the particular collection is complete, attach a barcode to the set of data resulting from the particular collection, and then copy the data set to the long-term storage area network **190** for permanent storage. In some embodiments, the barcode is generated at the time the collection process is initiated by the electronic discovery management server **110** and acts as a folder within which all files obtained through the collection process are placed. Thus, the barcode is stored with the collected data in the long-term storage area network **190** and is used to identify and access the data collected data at a later time. The log file of the barcode could include the time and date of the collection, the name of the requester, the particular file extension types requested, or any other information that would be useful in identifying or referring to the collection.

In some embodiments, the collections server **130** or another server transmits metadata about the collected data to the electronic discovery management server **110** to be stored in the database server **120**, for example, in the custodian's profile in the Unified Database **122**, in relation to the stored information about the particular collection, whether it was a local collection, an active email collection, a file server collection, etc. In other embodiments, the barcode information, or an actual link to the barcode in the long-term storage area network **190**, is stored within the case record **124** and/or the custodian profile in the Unified Directory **122** at the same time that the barcode is generated. In either instance, the barcode can be used for reference by the e-discovery manager by viewing the case record **124** or the custodian profile, as the case may be, at a later date to determine what collections have already occurred in the case or for the particular custodian. This is particularly advantageous in an enterprise environment or any environment in which multiple cases must be managed and custodians can be assigned to multiple cases, because it allows the e-discovery manager to readily locate and access data that was collected previously from a custodian, perhaps for a different case, and use the data, either for discovery purposes or to inform the collection process.

After the data has been copied to the long-term storage area network **190**, the collections server **130** compares the hashing of the data in permanent storage to the original data in the staging drive **180** and, if the hashing is identical, purges the data from the staging drive **180**. Once the data has entered the long-term storage area network **190**, it is not necessarily ready for review. Indeed, it is likely that the data may need to be processed before it is searchable and suitable for review by investigators and attorneys. For example, the files may be encrypted in the form in which they are collected and sent to the long-term storage area network **190**. Therefore, according

to some embodiments, the data may be copied to the conversion services server **170** where a series of decryption and standardization functions may be applied to it. After the data is decrypted and standardized, it is returned to the long-term storage area network **190** and may remain there to be accessed for review purposes.

With reference now to FIG. **5**, a block diagram is provided that illustrates the electronic discovery management structure of the present invention, according to some embodiments. As illustrated in FIG. **5**, certain processes described herein may be categorized within one of case management, as represented by Block **200**, custodian management, as represented by Block **220**, or data management, as represented by Block **240**. As described above, the electronic discovery system **100** is arranged such that cases, custodians and data may be managed independent of one another. However, there is still an element of the categorization of processes within the categories that is conceptual, and it should be understood that certain processes may be correctly assigned to more than one category. Therefore, while the architecture of the system **100** allows separate management of custodians, cases, and data, certain processes of the present invention may affect more than one of the foregoing.

The first process that falls within the case management category is creation of a matter or case as a framework for litigation support activities, as shown in Block **202**. As described above, the e-discovery manager may enter into the user interface **118** certain information about a particular matter or case, such as a case name and/or number, a short description of the matter/case, a legal identifier, the particular requester (i.e., who asked for the case to be opened), managers or contacts for the matter (i.e., individuals involved in the substance of the matter rather than the process, like the e-discovery manager) etc.

It is noted that custodian information is stored separately from the case information allowing for the same custodian in multiple cases. This provides for the electronic discovery system of the present invention to have scalability, whereby evidence associated with one custodian may be used in multiple cases.

The electronic discovery management server **110** stores this information in the case database **124** in the database server **120**. The case database **124** houses this information such that all information relating to a particular matter or case is related within the case database **124** and a user, such as a manager or contact, can use the user interface **118** to view and edit a profile of the matter or case.

The next process within case management is the creation of preservation notices and surveys specific to the matter, as shown in Block **204**. In this regard, the e-discovery manager may, through the user interface **118**, either generate a new preservation notices or surveys relevant to the particular case or matter to be stored in the case profile in the case database **124** or, alternatively, link a preservation notice or survey already stored in the database server **120** to the case profile of the specific case or matter at issue. Also within case management is the creation of search terms pertinent to the case, as represented by Block **206**. As described above, the e-discovery manager or a contact or manager for the case may use the user interface **118** to input individual search terms or search term sets to be applied to the data harvested in the case. In some embodiments, the search terms may be limited to be used with particular custodians and/or with particular harvested data types. The search terms will be saved in the case database **124** so that they may be readily applied to harvested data and used in connection with storing the resulting responsive data.

The processes of entering relevant attachments, notes and updates to a particular case or matter also falls within the case management category, as demonstrated by Blocks **208** and **210**. The e-discovery manager or a case contact or manager may use the user interface **118** to upload documents and enter notes and other relevant data, including updates and reminders, to be stored in the case profile of the case in the case database **124**. Once these attachments, notes and updates are added, they may be referenced whenever a user views the case profile through the user interface **118**. The cost estimation modules of the present invention are also processes that are categorized as case management processes, as shown in Block **212**. In this regard, the electronic discovery management server **110** utilizes a cost estimation tool to determine the cost of harvesting and reviewing data, based on a number of factors including, for example, number of custodians, amount of harvested data, data types, historical averages for specific data types, etc. Finally, case management also includes a number of tasking and workflow processes that are represented by block **214**.

Moving now to custodian management, certain processes falling within the category of custodian management are shown in Block **220**. While the processes involving generation of the Unified Directory **122** certainly could be categorized as custodian management, the processes shown in FIG. **5** include those processes involving management of custodians within the scope of a case or matter. In that regard, the first process of custodian management included in FIG. **5** is the addition of custodians to a case or matter, as shown in Block **222**. As described above, the e-discovery manager may use the user interface **118** to link a custodian's profile from the Unified Directory **122** to the particular case profile in the case database **124**. Thus, the custodian profile and case profile are correlated. The next processes within custodian management is the transmission of preservation notices and surveys to custodians, as shown in Block **224**, and the presentation of the surveys to custodians, as shown in Block **226**. It should be understood that, in some embodiments, the system that transmits the surveys may operate independently of the system by which the preservation notices are sent to custodians. In some embodiments, the electronic discovery management server **110** uses the contact information in the custodian's profile in the Unified Directory **122** to transmit the preservation notice(s) and survey(s) stored in the case profile to the custodian. In some embodiments, a standard email function is used, so that the only information needed from the Unified Directory **122** is the custodian's email address. When the custodian checks her email, the request to complete the survey will appear as a message therein, and when she opens that message content, the survey will be presented to her. The survey may be configured such that when she fills it out, the survey is automatically transmitted back to the database server **120** for storage in the case profile and the custodian's profile.

Also falling within custodian management is the process of releasing custodians from a matter to a case, as shown in Block **228**. The e-discovery manager uses the user interface **118** to mark the custodian's profile so that the custodian is now activated for collection of data. This may occur within the case database **124** since the custodian's profile is linked thereto. Once the custodian is released, the electronic discovery management server **110** may access the custodian's profile and initialize collection based on the various data storage locations identified in the profile. Therefore, as represented by Block **230**, the electronic discovery management server **110** may automatically determine the data types and locations of data to be harvested by accessing the custodian's profile in the Unified Directory **122**. Alternatively, the e-discovery

21

manager may manually make the same determination by accessing and viewing the custodian's profile. Finally, as with case management, custodian management also includes a number of tasking and workflow processes that are represented by Block 232.

The last category is data management, represented by Block 240. One major set of processes within data management are the processes relating to the harvesting of data, as shown in Block 242. These processes include the collection of data from all the different storage areas of a particular custodian, including the custodian's local storage on her personal computer(s), the custodian's network storage areas, the custodian's email, and any other areas, as are described herein. All of the data in the various storage areas is copied and transmitted to the collections server 130, as described in detail for each particular collection tool or process. Upon reaching the collections server 130, data resulting from a particular collection is temporarily stored in the short-term staging drive 180 until the collection is complete, at which point it is stored in the long-term storage area network 190 in association with a specific identifying barcode. The foregoing process is represented by Block 244. The data may require decryption or standardization functions to be applied to it in order for it to be searchable and/or otherwise usable, so the next process that falls within data management is the copying of the data to the conversion services server 170 for analysis and conversion as necessary, as shown in Block 246. Once the data is converted, it is returned to the long-term storage area network 190 to be used in review.

Also falling within data management is the association of particular data sets with particular sets of search terms stored in the case profile of the case database 124. In this regard, certain search terms stored in the case profile are stored with the intention of being applied to certain types of data, certain custodian's data, and/or a particular barcode associated with a certain collected data set. Alternatively, certain search terms may be applied to all data collected for a specific case. In either instance, the electronic discovery management server 110 accesses the case profile, determines the search terms to be applied, and associates the search terms with the barcode of the appropriate data sets in long-term storage. Thus, the search terms will be applied to that data and the results will be generated and presented to reviewers for analysis. Finally, as with the other management categories, data management also includes a number of tasking and workflow processes that are represented by Block 250.

With reference to FIG. 6, an exemplary process for managing a case is provided, in accordance with one embodiment of the present invention. As represented by Block 302, a case or matter is created by the e-discovery manager and stored in the case database 124. Next, custodians are added to the case, as shown in Block 304, by linking the custodian profiles of the Unified Directory 122 to the case profile. Next, as represented by Block 306, the e-discovery manager and/or the case contact or manager adds search terms to be applied to data harvested for the case, including instructions as to applying the search terms to particular data types or custodians. Block 310 represents the determination that must be made as to whether there is a matter or just a case. If there is no matter because preservation notices are not required, for example, for an audit, then the process will move straight to the initialization of data collection. On the other hand, if there is matter, rather than just a case, then the creation of preservation notices is required, as shown in Block 312.

The preservation notice, as shown in Block 314 is transmitted to the custodians added to the matter, perhaps using email. As shown in Block 316, a reminder notice module may

22

be employed. As shown in Block 318, the reminder notice module transmits periodic reminder notices to custodians. The notices may be sent over email and may remind custodians about the preservation notice and/or remind custodians to fill out surveys. With regard to surveys, in the event a survey is required or desired, according to Block 320, a survey is created. The survey may be saved in the case profile in the case database 124. As shown in Block 322, it is possible to enable the survey to be attached to and transmitted with the preservation notices.

Next, as shown in Block 324, the e-discovery manager may release custodians from the matter to the case, which initializes collection of the custodian's data. As shown in Block 326, the e-discovery manager or the electronic discovery management server 122 accesses the custodian profile, determines the data types and location to be collected, and initializes the applicable collection tools to go collect the data. Once the data has been collected and a unique barcode has been assigned to each dataset based on the particular custodian and storage location from which it originated, as shown in Block 328, the search terms previously stored in the case profile may be assigned to the dataset based on the input instructions regarding the search terms. These search terms may be applied to the dataset and the results saved to be presented to reviewers for analysis.

With reference to FIG. 7, an exemplary process for managing a custodian is provided, in accordance with one embodiment of the present invention. First, as represented by Block 402, a custodian is added to a matter or case. In this regard, the custodian's profile in the Unified Directory 122 is linked to the relevant case or matter profile. In order to locate the custodian's profile, a custodian search module may be employed, as shown in Block 404. Therefore, the e-discovery manager may enter any identifying information about the custodian, whether it is the custodian's name, network user identification, email address, etc. The custodian search module will take the input information and search the Unified Directory 122 for a match. If more than one match is obtained, the user interface 118 will present all matches and allow the e-discovery manager to browse the associated profiles to determine the intended custodian. In this way, the correct custodian is identified and the profile of that custodian is linked to the appropriate case or matter.

As represented by Block 406, the electronic discovery management server 110 may determine whether the particular custodian added is a member of the enterprise "do-not-contact list." In this regard, there may be an indication in the custodian's profile in the Unified Directory 122 that the particular custodian should not be contacted regarding collections, and an alternative contact should be used, such as an administrative assistant of the custodian. Alternatively, there may be a separate do-not-contact list stored in the database server 120 that must be accessed and searched to determine whether or not the custodian appears on that list. In either instance, a determination is made as to whether or not the custodian should be directly contacted, and in the event the custodian should not be directly contacted, the contact information for the custodian's assistant (or other stand-in) should be obtained. This information will be used later for transmitting preservation notices and surveys.

Next, in accordance with Block 408, a determination is made by the electronic discovery management server 110 as to whether the custodian has been added to a matter or a case. If it is a case, then the custodian is verified, as shown in Block 424, supplemental data may be added to the custodian profile in the Unified Directory 122 as required, as shown in Block 426, and then the various collection tools are initialized by the

23

electronic discovery management server **110** for collection of the custodian's data, as shown in Block **428**. On the other hand, if it is a matter, then preservation notices may be required. Therefore, as shown in Block **410**, a preservation notice is sent via email to the custodian or custodian stand-in. As shown in Block **412**, the custodian may then be inactivated from the case because, for some reason, data does not need to be collected from the custodian. In the future, when it comes time to collect from the custodian, the custodian will be reactivated, as shown in Block **422**. For example, a particular individual may have been added as a potential custodian, but was later deemed to be unimportant based on initial review, thus leading to inactivation. On secondary review, however, a realization may be made that this person is of importance after all, thus necessitating re-activation. Such inactivation and reactivation does not affect the actual data collection process and only impacts the matter (pre-collection) level of a particular case.

After a preservation notice is sent, a determination is made by the electronic discovery management server **110** as to whether a survey is required, as shown in Block **414**. It should be noted that in alternate embodiments the decision on whether to send a survey may be made prior to sending the preservation notice. In such alternate embodiments, if the survey is required, it may become a component of the preservation notice and, thus, accessed simultaneously by the custodian. If a survey is required, it is transmitted in conjunction with a preservation notice, and the answers are collected by the electronic discovery management server **110** and stored in the database server **120**, as shown in Block **416**. Reminder notices for the preservation notices and surveys may also be transmitted to the custodian, as shown in Block **420**. Next, once it is time to collect data, the custodian is released from the matter to the case, as shown in Block **418**, and the various collection tools are initialized by the electronic discovery management server **110** for collection of the custodian's data, as shown in Block **428**. In this process, the custodian's profile in the Unified Directory **122** is accessed in order to determine the various locations where the custodian may have stored data. Finally, as shown in Block **430**, the custodian's data is collected.

Referring to FIGS. **8** and **9**, flow diagrams are presented of a method **500** for harvest data from various data sources, in accordance with embodiments of the present invention. At Event **502**, the process whereby data is collected is initiated and, at Event **504**, the type of data is identified. Data Block **506** signifies active email that is collected from an exchange system or the like. At Event **508** the automated active email collection tool is implemented to collect email from identified email address. As previously noted, and in accordance with present embodiments of the invention, if a custodian profile (for a custodian released for collection) includes an email address for an email account on the enterprise email server (**160**), then the electronic discovery management server (**110**) may undertake to collect the files from the enterprise email server (**160**) by initializing the active email collection tool (**136**) running on collections server (**130**). In some embodiments, the active email collection tool (**136**) is configured to access the particular Microsoft Exchange server within the enterprise email server **160** on which the custodian's account resides (which is known based on the information included in the Unified Directory **122**), copy all email located there, including emails deleted up to a designated prior period, for example, seven days prior to the collection, and transmit the copied emails to the collections server (**130**). The email collection tool is also capable of implementing bulk requests and for collecting email on a scheduled basis, such as daily. The

24

email collection tool is additionally capable of being implementing enterprise wide and requires no server identifiers or the like to collect the active email. In this regard, the email collection tool (**136**) serves to reduce security risk.

At Event **510**, a barcoding tool is implemented at a staging location, such as short-term staging drive (**180**) to attach a barcode to the set of email resulting from the particular collection. The barcoded data is then copied and communicated to the long-term storage area network (**190**) for permanent storage. Furthermore, the collections server (**130**) transmits the barcode information to the electronic discovery management server (**110**) to be stored in the database server (**120**), for example, in the custodian's profile in the Unified Database (**122**), in relation to the stored information about the particular collection. Therefore, the barcode can be used for reference at a later date to determine the origin of the data. After the data has been copied to the long-term storage area network (**190**), the collections server (**130**) compares the hashing of the data in permanent storage to the original data in the staging drive (**180**) and, if the hashing is identical, purges the data from the staging drive (**180**). As such, barcoding is performed without the need to execute the barcoding tool on an exchange server and, as such no human intervention is needed in the barcode process. In accordance with embodiments of the present invention, one barcode may be assigned per custodian, per data type and per event (i.e., case, matter, etc.)

At Event **512**, the collected email data may be associated with a specific search term set or sets. When the search terms are applied, a listing of the files and documents including those terms (the "search term hit list") are presented to the reviewer and also stored in the database server (**120**). The reviewer may provide an indication of this to the electronic discovery management server **110**, which may then make a determination that other documents within the search term hit list are more likely to be responsive.

At Event **514**, the collected and barcoded active email data is copied to a processing drive for subsequent analysis. It should be noted that the nature of email data obviates the need to perform conversion and/or decryption on the data set. At Event **516**, the active email data set is loaded into the analysis tool and, at Event **518**, the data set is exported to the requestor/reviewer for analysis.

Data Block **520** signifies other non-exchange server based email, such as email accessed through a client-server, collaborative application, such as Lotus Notes® or the like. At Event **522**, NSF files or any other file types associated with non-exchange server based email is manually harvested from an enterprise-grade email server having collaborative capabilities, such as a Lotus Domino server or the like.

At Event **522**, a barcoding tool is implemented at a staging location, such as short-term staging drive (**180**) to attach a barcode to the set of non-exchange server email resulting from the particular collection. The barcoded data is then copied and communicated to the long-term storage area network (**190**) for permanent storage. Furthermore, the collections server (**130**) transmits the barcode information to the electronic discovery management server (**110**) to be stored in the database server (**120**), for example, in the custodian's profile in the Unified Database (**122**), in relation to the stored information about the particular collection. Therefore, the barcode can be used for reference at a later date to determine the origin of the data. After the data has been copied to the long-term storage area network (**190**), the collections server (**130**) compares the hashing of the data in permanent storage

to the original data in the staging drive (180) and, if the hashing is identical, purges the data from the staging drive (180).

At Event 526, the collected non-exchange server email data may be associated with a specific search term set or sets. When the search terms are applied, a listing of the files and documents including those terms (the "search term hit list") are presented to the reviewer and also stored in the database server (120). The reviewer may provide an indication of this to the electronic discovery management server 110, which may then make a determination that other documents within the search term hit list are more likely to be responsive.

At Event 528, the NSF files or any other file types associated with non-exchange server based email that may be encrypted is decrypted using a decryption tool, in accordance with embodiments of the present invention. The encryption of NSF files occurs at the user level and, therefore only the user has the password necessary for decryption. The decryption tool allows for decryption of the NSF file-type data without the knowledge of the user/encrypter. The decryption tool finds ID files that exist anywhere in the enterprise system, creates a database of the ID files, associates the database with the user/encrypter and subsequently decrypts the data.

At Event 530, the non-exchange server email data set is loaded into the analysis tool and, at Event 532, the data set is exported to the requestor/reviewer for analysis.

Data Block 534 signifies journaled data, such as electronic commerce data stored on a repository for the purpose of regulation, compliance to regulating bodies, such as the Securities and Exchange Commission (SEC) or the like. At Event 536, criteria is extracted from input system and manually entered in a designated third party system for data retrieval.

At Event 538, the barcoding tool is implemented at a staging location, such as short-term staging drive (180) to attach a barcode to the set of journaled data resulting from the particular collection. The barcoded data is then copied and communicated to the long-term storage area network (190) for permanent storage. At Event 540, the collected and bar-coded journaled data may be associated with a specific search term set or sets.

At Event 542 source-to-processing is implemented to insure that any loose files are properly formatted in a standardized format. In this regard, according to one embodiment of the invention, loose files are examined for relevancy and, if relevant, stored in a proper data format, such as a PST file or the like. The metadata associated with the non-standardized files is retained and remains with the reformatted data files. Source to processing file conversions may be required on EML formatted files, MSG formatted files and the like.

At Event 544, the journaled data set is loaded into the analysis tool and, at Event 546, the journaled data set is exported to the requestor/reviewer for analysis.

Referring to FIG. 9, data block 548 signifies data from a local Personal Computer (PC), such as enterprise PC (140). At Event 550, the local collection tool (132) is implemented to collect data from designated PCs by taking a "snapshot" of the device's hard drive. According to one embodiment of the invention, the local collection tool may be autodeployed thus, obviating the need for any manual entry by the e-discovery manager or the like. In other embodiments of the invention, the local collection tool (132) may be employed to collect data from network storage.

At Event 552, the barcoding tool is implemented at a staging location, such as short-term staging drive (180) to attach a barcode to the set of local PC data resulting from the particular collection. The barcoded data is then copied and communicated to the long-term storage area network (190) for

permanent storage. At Event 554, the collected and barcoded local PC data may be associated with a specific search term set or sets.

At Event 556 source-to-processing is implemented to insure that any loose files are properly formatted in a standardized format. In this regard, according to one embodiment of the invention, loose files are examined for relevancy and, if relevant, stored in a proper data format, such as a PST file or the like. The metadata associated with the non-standardized files is retained and remains with the reformatted data files. Source to processing file conversions may be required on EML formatted files, MSG formatted files, IPD formatted files and the like.

At Event 558, the local PC files that may be encrypted are decrypted using a decryption tool, in accordance with embodiments of the present invention. The decryption tool allows for decryption of the PC files data without the knowledge of the user/encrypter. The decryption tool finds ID files that exist anywhere in the enterprise system, creates a database of the ID files, associates the database with the user/encrypter and subsequently decrypts the data.

At Event 560, the local PC data set is loaded into the analysis tool and, at Event 562, the local PC data set is exported to the requestor/reviewer for analysis.

Data block 564 signifies data from network storage, such as a shared drive or HomeSpace. At Event 566, the file server collection tool (134) is implemented to automatically collect data from shared drives and/or HomeSpace. According to one embodiment of the invention, the file server collection tool (134) may be autodeployed thus, obviating the need for any manual entry by the e-discovery manager or the like.

At Event 568, the barcoding tool is implemented at a staging location, such as short-term staging drive (180) to attach a barcode to the set of network storage data resulting from the particular collection. The barcoded data is then copied and communicated to the long-term storage area network (190) for permanent storage. At Event 570, the collected and bar-coded network storage data may be associated with a specific search term set or sets.

At Event 572 source-to-processing is implemented to insure that any loose files are properly formatted in a standardized format. In this regard, according to one embodiment of the invention, loose files are examined for relevancy and, if relevant, stored in a proper data format, such as a PST file or the like. The metadata associated with the non-standardized files is retained and remains with the reformatted data files. Source to processing file conversions may be required on EML formatted files, MSG formatted files, IPD formatted files and the like.

At Event 574, the network storage files that may be encrypted are decrypted using a decryption tool, in accordance with embodiments of the present invention. The decryption tool allows for decryption of the network storage data without the knowledge of the user/encrypter. The decryption tool finds ID files that exist anywhere in the enterprise system, creates a database of the ID files, associates the database with the user/encrypter and subsequently decrypts the data.

At Event 576, the network storage data set is loaded into the analysis tool and, at Event 578, the network storage data set is exported to the requestor/reviewer for analysis.

Data block 580 signifies electronic data for forensics. At Event 582, a forensic collector tool, such as EnCase® may be executed on the devices of interest to collect data. According to one embodiment of the invention, the forensic collector tool may be automatically deployed on the device of interest without the knowledge of the device user. In accordance with

another embodiment of the invention, a computer watcher tool may be implemented (not shown in FIG. 9) that watches the network to determine the addition or subtraction of computers to the network based on ID's/IP addresses returned from the network.

At Event 584, the barcoding tool is implemented at a staging location, such as short-term staging drive (180) to attach a barcode to the set of forensic data resulting from the particular collection. The barcoded data is then copied and communicated to the long-term storage area network (190) for permanent storage. At Event 586, the collected and barcoded forensic data may be associated with a specific search term set or sets.

At Event 588 source-to-processing is implemented to insure that any loose files are properly formatted in a standardized format. In this regard, according to one embodiment of the invention, loose files are examined for relevancy and, if relevant, stored in a proper data format, such as a PST file or the like. The metadata associated with the non-standardized files is retained and remains with the reformatted data files. Source to processing may be required on EML formatted files, MSG formatted files, IPD formatted files and the like.

At Event 590, the forensic files that may be encrypted are decrypted using a decryption tool, in accordance with embodiments of the present invention. The decryption tool allows for decryption of the network storage data without the knowledge of the user/encrypter. The decryption tool finds ID files that exist anywhere in the enterprise system, creates a database of the ID files, associates the database with the user/encrypter and subsequently decrypts the data.

At Event 592, the forensic data set is loaded into the analysis tool and, at Event 594, the network storage data set is exported to the requestor/reviewer for analysis.

Data block 596 signifies collaborative data, such as data residing at discovery sites, for example LiveLink® or the like. At Event 598, a discovery site collector tool, such as a LiveLink® collector tool may be executed on the devices of interest to collect data. According to one embodiment of the invention, the discovery site collector preserves at least a portion of the discovery site database in the e-discovery database, including all files and all revisions of the files. In this regard, the discovery site collector tool queries against the database to define what files need to be retrieved, then copies those files based on the result of the query. Metadata pertaining to the files is retained in the case management system tables. In accordance with another embodiment of the invention, the discovery site collector tool collects the documents and the related metadata and uses the metadata to automatically rename the files.

At Event 600, the barcoding tool is implemented at a staging location, such as short-term staging drive (180) to attach a barcode to the set of discovery site data resulting from the particular collection. The barcoded data is then copied and communicated to the long-term storage area network (190) for permanent storage. At Event 602, the collected and barcoded discovery site data may be associated with a specific search term set or sets.

At Event 604 source-to-processing is implemented to insure that any loose files are properly formatted in a standardized format. In this regard, according to one embodiment of the invention, loose files are examined for relevancy and, if relevant, stored in a proper data format, such as a PST file or the like. The metadata associated with the non-standardized files is retained and remains with the reformatted data files. Source to processing may be required on EML formatted files, MSG formatted files, IPD formatted files and the like.

At Event 606, the discovery site data set is loaded into the analysis tool and, at Event 608, the discovery site data set is exported to the requestor/reviewer for analysis.

In order to illustrate the efficiencies and advantages provided by the unique structure of embodiments of the present invention, that is, separating the storage and management of custodians, cases, and collected data but allowing linkages between them, FIGS. 10-14 provide illustrations of the user interface 118 visible to the e-discovery manager conducting electronic discovery using an exemplary electronic discovery system in accordance with one embodiment of the present invention. Referring to FIG. 10, a screen shot of an exemplary case record within the case database 124 is provided. The most general case information appears on the main page, with options on the left-hand side given to link to other information about the case on different pages, most notably, custodians and evidence (collected data). As discussed previously, both the custodian profiles and the collected data are not housed exclusively in the case record, but rather are stored elsewhere (the Unified Directory 122 and the long-term storage area network 190 respectively) and linked to the case record to promote efficiency within an enterprise electronic discovery environment.

Referring to FIG. 11, a screen shot of the custodian page of the case record is provided. The custodian list shown is housed within the case record in the case database 124, but each custodian name is a hyperlink to the custodian profile within the Unified Directory 122. In some embodiments where the custodian profile in the Unified Directory 122 does not contain all information about the custodian that may have been obtained during various cases and/or matters; the hyperlink shows the custodian record across all cases, including the information retrieved from the Unified Directory 122. Thus, all of the information regarding the custodian does not need to be copied or manually input to the case record. This is particularly advantageous where a single custodian is assigned to multiple cases. Rather, according to embodiments of the present invention, the electronic discovery management server 110, upon a particular collection being initialized, may access the Unified Directory 122 in order to determine the information about the particular custodian, including the data storage locations that the custodian uses, such as workstations, HomeSpaces, email and shared drives, and use that information to automatically begin the collection process.

Referring to FIG. 12, a screen shot of the custodian profile within the Unified Directory 122 is provided. As shown, the Unified Directory 122 may be queried with particular information about one or more custodian(s), for example, name or email address, and the matching results will be provided. This would occur, for example, when custodians are added to cases, as discussed in detail above. Furthermore, if the e-discovery manager is within the case record and viewing the custodian page of the case record, as illustrated in FIG. 11, the hyperlinks provided in the custodian names set forth in the custodian list will allow the e-discovery manager to access a page very similar to this one, except that the Directory Lookup feature will not appear. Rather, activating that hyperlink in the case record will bring the e-discovery manager to the custodian profile, where the information about the custodian and his or her data storage locations may be reviewed. Thus, these screen shots demonstrate how custodians are managed and stored separately from the cases with which they may be associated according to some embodiments of the present invention.

Referring now to FIG. 13, a screen shot of the evidence page within the case record is shown. As discussed previously, evidence metadata, like custodian information, is

stored separately from the case record and linked to the cases and/or custodians to which it relates. This allows the data collected for one custodian in a particular case to be readily accessed and used in another case. As shown in FIG. 13, a list is provided within the case record that sets forth all custodians from whom data has been collected or identified for use within that specific case. Furthermore, the list of the custodian names contain hyperlinks to the custodians' profiles within the Unified Directory 122 and/or the custodian record across all cases (according to different embodiments), which profile or record houses a full list of the barcodes associated with data historically collected from that custodian. Thus, from the case record, it is possible, according to some embodiments of the present invention, to readily access both a list of all collections that have been performed for that specific case, and, through activating one hyperlink, a list of all collections that have been performed with respect to a particular custodian.

In that regard, referring now to FIG. 14, a screen shot showing the list of barcodes associated with a particular custodian within the Unified Directory 122 is shown. Thus, the list includes all data collected from the custodian, for any number of cases. As discussed previously, this list may be used to access the data at any time, even if the e-discovery manager is working on an entirely separate case. This reduces the instances of over-collection and wasted effort and storage space by promoting the sharing of data among cases. The screen shots provided and the processes described merely depict one embodiment of the present invention. It should be appreciated that there will be numerous ways to implement the novel concept of structuring the electronic discovery system such that the case, custodian, and collected data management processes are separate.

Thus, present embodiments herein disclosed provide for improvements in electronic discovery. Embodiments herein disclosed provide for an enterprise wide e-discovery system that provides for data to be identified, located, retrieved, preserved, searched, reviewed and produced in an efficient and cost-effective manner across the entire enterprise system. In addition, by structuring management of e-discovery based on case/matter, custodian and data and providing for linkage between the same, further efficiencies are realized in terms of identifying, locating and retrieving data and leveraging results of previous e-discoveries with current requests.

While certain exemplary embodiments have been described and shown in the accompanying drawings, it is to be understood that such embodiments are merely illustrative of and not restrictive on the broad invention, and that this invention not be limited to the specific constructions and arrangements shown and described, since various other changes, combinations, omissions, modifications and substitutions, in addition to those set forth in the above paragraphs, are possible.

Those skilled in the art may appreciate that various adaptations and modifications of the just described embodiments can be configured without departing from the scope and spirit of the invention. Therefore, it is to be understood that, within the scope of the appended claims, the invention may be practiced other than as specifically described herein.

The invention claimed is:

1. A method for providing an electronic discovery system, comprising:

providing for a case management level within an electronic discovery system, wherein the electronic discovery system provides for electronic data to be located, collected and searched for a purpose of using the electronic data as

evidence in one or more of a legal proceeding, an audit a regulatory investigation or a forensic investigation; linking, by a computer processor device, a custodial management level to the case management level;

linking, by a computer processor device, a data management level to the case management level and the custodial management level;

generating, by a computing device processor, an electronic discovery case at the case management level and adding, by a computing device processor, a plurality of custodians to the electronic discovery case, wherein the linking of the custodial management level to the case management level provides for, in response to adding the custodians to the electronic discovery case, (1) accessing profile data of the plurality of custodians, which is stored in custodian profiles at a first storage location, from case data related to the electronic discovery case, which is stored in a case-specific file at a second storage location and (2) accessing the case data from the custodian profiles; and

collecting, by a computing device processor, a data set determined to be associated with each of the plurality of custodians, wherein the linking of the data management level to the case management level and custodial management level provides for, in response to collecting the electronic data (1) accessing the data set, which is stored in an electronic data file at a third storage location, from either the case data or a customer profile associated with a corresponding custodian, (2) accessing the customer profile from the data set, and (3) accessing the case data from the data set.

2. The method of claim 1, wherein providing for the case management level further comprises generating, by a computer processor, one or more preservation notices specific to a case.

3. The method of claim 2, wherein linking the custodial management level to the case management level further comprises communicating, by a computer processor, the one or more preservation notices to one or more custodians.

4. The method of claim 1, wherein providing for the case management level further comprises generating, by a computer processor, one or more surveys specific to a case.

5. The method of claim 4, wherein linking the custodial management level to the case management level further comprises communicating, by a computer processor, the one or more surveys to one or more custodians.

6. The method of claim 1, wherein providing for the case management level further comprises providing for search terms linked with the electronic discovery case.

7. The method of claim 1, wherein linking the custodial management level to the case management level further comprises releasing, by a computer processor, one or more previously added custodians from one of a case or a matter.

8. The method of claim 1, wherein linking the custodial management level to the case management level further comprises identifying, by a computer processor, data types to be retrieved for custodians.

9. The method of claim 1, wherein collecting the data set further comprises storing, in computer memory, the collected data set on a long-term storage media.

10. The method of claim 1, wherein collecting the data set further comprises linking, by a computer processor, the collected data set with one or more search term sets provided for at the case management level.

11. The method of claim 1, wherein collecting the data set further comprises copying, by a computer processor, the collected data set to a processing drive for analysis.

31

12. An electronic discovery system provides for electronic data to be located, collected and searched for a purpose of using the electronic data as evidence in one or more of a legal proceeding, an audit a regulatory investigation or a forensic investigation, the system comprising:

- a computing platform including a memory and at least one processor in communication with the memory; and
- an electronic discovery module stored in the memory, executable by the at least one processor, including a case management level, a custodial management level linked to the case management level and a data management level linked to the case management level and the custodial management level and configured to:
 - generate an electronic discovery case at the case management level and add a plurality of custodians to the electronic discovery case, wherein the linking of the custodial management level to the case management level provides for, in response to adding the custodians to the electronic discovery case, (1) accessing profile data of the plurality of custodians, which is stored in custodian profiles at a first storage location, from case data related to the electronic discovery case, which is stored in a case-specific file at a second storage location and (2) accessing the case data from the custodian profiles, and
 - collect a data set determined to be associated with each of the plurality of custodians, wherein the linking of the data management level to the case management level and custodial management level provides for, in response to collecting the electronic data, (1) accessing the data set, which is stored in an electronic data file at a third storage location, from either the case data or a customer profile associated with a corresponding custodian, (2) accessing the customer profile from the data set, and (3) accessing the case data from the data set.

13. The system of claim **12**, wherein the case management level is configured to provide for generation of preservation notices specific to the electronic discovery case and surveys specific to the electronic discovery case.

32

14. A computer program product including a non-transitory computer-readable medium comprising:

- instructions for causing a computer to link a custodial management level to a case management level provided for within an electronic discovery system, wherein the electronic discovery system provides for electronic data to be located, collected and searched for a purpose of using the electronic data as evidence in one or more of a legal proceeding, an audit a regulatory investigation or a forensic investigation;
- instructions for causing a computer to link a data management level to the case management level and the custodial management level;
- instructions for causing a computer to generate an electronic discovery case at the case management level and add a plurality of custodians to the electronic discovery case, wherein the linking of the custodial management level to the case management level provides for, in response to adding the custodians to the electronic discovery case, (1) accessing profile data of the plurality of custodians, which is stored in custodian profiles at a first storage location, from case data related to the electronic discovery case, which is stored in a case-specific file at a second storage location and (2) accessing the case data from the custodian profiles; and
- instructions for causing a computer to collect a data set determined to be associated with each of the plurality of custodians, wherein the linking of the data management level to the case management level and custodial management level provides for, in response to collecting the electronic data (1) accessing the data set, which is stored in an electronic data file at a third storage location, from either the case data or a customer profile associated with a corresponding custodian, (2) accessing the customer profile from the data set, and (3) accessing the case data from the data set.

15. The computer program product of claim **14**, further comprising instructions for causing a computer to generate preservation notices and surveys specific to the case.
