## 7-SUBSTITUTED 3-NITRO-PYRAZOLO [1,5-a] PYRIMIDINES

**Technical field**

This invention is directed to agents with affinity for GABA<sub>A</sub> receptor, more specifically to pyrazolo[1,5-a]pyrimidines.

**Background of the invention**

GABA<sub>A</sub> receptor ( $\gamma$ -aminobutyric acid<sub>A</sub>) is a pentameric protein which forms a membrane ion channel. GABA<sub>A</sub> receptor is implicated in the regulation of sedation, anxiety, muscle tone, epileptogenic activity and memory functions. These actions are due to defined subunits of GABA<sub>A</sub> receptor, particularly the  $\alpha_1$ - and  $\alpha_2$ -subunits.

Sedation is modulated by the  $\alpha_1$ -subunit. Zolpidem is characterized by a high affinity for the  $\alpha_1$ -receptors and its sedative and hypnotic action is mediated by these receptors in vivo. Similarly, the hypnotic action of zaleplon is also mediated by the  $\alpha_1$ -receptors.

The anxiolytic action of diazepam is mediated by the enhancement of GABAergic transmission in a population of neurons expressing the  $\alpha_2$ -receptors. This indicates that the  $\alpha_2$ -receptors are highly specific targets for the treatment of anxiety.

Muscle relaxation in diazepam is mainly mediated by  $\alpha_2$ -receptors, since these receptors exhibit a highly specific expression in spinal cord.

5 The anticonvulsant effect of diazepam is partly due to  $\alpha_1$ -receptors. In diazepam, a memory-impairing compound, anterograde amnesia is mediated by  $\alpha_1$ -receptors.

10 GABA<sub>A</sub> receptor and its  $\alpha_1$ - and  $\alpha_2$ -subunits have been widely reviewed by H. Möhler et al. (J. Pharmacol. Exp. Ther., 300, 2-8, 2002); H. Möhler et al. (Curr. Opin. Pharmacol., 1, 22-25, 2001); U. Rudolph et al. (Nature, 401, 796-800, 1999); and D. J. Nutt et al. (Br. J. Psychiatry, 179, 390-396, 2001).

15

Diazepam and other classical benzodiazepines are extensively used as anxiolytic agents, hypnotic agents, anticonvulsants and muscle relaxants. Their side effects include anterograde amnesia, decrease in motor activity  
20 and potentiation of ethanol effects.

In this context, the compounds of this invention are ligands of  $\alpha_1$ - and  $\alpha_2$ -GABA<sub>A</sub> receptor for their clinical application in sleep disorders, preferably insomnia,  
25 anxiety and epilepsy.

Insomnia is a highly prevalent disease. Its chronicity affects 10% of the population and 30% when transitory insomnia is computed as well. Insomnia describes the  
30 trouble in getting to sleep or staying asleep and is associated with hangover effects the next day such as weariness, lack of energy, low concentration and

irritability. The social and health impact of this complaint is important and results in evident socioeconomic repercussions.

5 Pharmacological therapy in the management of insomnia firstly included barbiturates and chloral hydrate, but these drugs elicit numerous known adverse effects, for example, overdose toxicity, metabolic induction, and enhanced dependence and tolerance. In addition, they  
10 affect the architecture of sleep by decreasing above all the duration and the number of REM sleep stages. Later, benzodiazepines meant an important therapeutic advance because of their lower toxicity, but they still showed serious problems of dependence, muscle relaxation,  
15 amnesia and rebound insomnia following discontinuation of medication.

The latest known therapeutic approach has been the introduction of non-benzodiazepine hypnotics, such as  
20 pyrrolo[3,4-b]pyrazines (zopiclone), imidazo[1,2-a]pyridines (zolpidem) and, finally, pyrazolo[1,5-a]pyrimidines (zaleplon). Later, two new pyrazolo[1,5-a]pyrimidines, indiplon and ocinaplon, have entered into development, the latter with rather anxiolytic action.  
25 All these compounds show a rapid sleep induction and have less hangover effects the next day, lower potential for abuse and lower risk of rebound insomnia than benzodiazepines. The mechanism of action of these compounds is the allosteric activation of GABA<sub>A</sub> receptor  
30 through its binding to benzodiazepine binding site (C. F. P. George, The Lancet, 358, 1623-1626, 2001). While benzodiazepines are unspecific ligands at GABA<sub>A</sub> receptor binding site, zolpidem and zaleplon show a greater

selectivity for  $\alpha_1$ -subunit. Notwithstanding that, these drugs still affect the architecture of sleep and may induce dependence in long-term treatments.

5 In US patent documents No. 4,626,538 and No. 6,399,621, and European Patent No. 129,847 hypnotic pyrazolo[1,5-a]pyrimidines are disclosed. These patents correspond to zaleplon, indiplon and ocinaplon, respectively.

10 Research for new active compounds in the management of insomnia answers an underlying health need, because even recently introduced hypnotics still affect the architecture of sleep and may induce dependence in long-term treatments.

15 It is therefore desirable to focus on the development of new hypnotic agents with a lower risk of side effects.

Thus, the present invention is directed to new 7-substituted 3-nitro-pyrazolo[1,5-a]pyrimidines which are  
20 active versus GABA<sub>A</sub> receptor and, particularly, versus its  $\alpha_1$ - and  $\alpha_2$ -subunits. Consequently, the compounds of this invention are useful in the treatment and prevention of all those diseases mediated by  $\alpha_1$ - and  $\alpha_2$ -  
25 GABA<sub>A</sub> receptor. Non-limitative examples of such diseases are sleep disorders, preferably insomnia, anxiety and epilepsy. Non-limitative examples of the relevant indications of the compounds of this invention are all those diseases or conditions that need an induction of  
30 sleep, such as insomnia or anesthesia, an induction of sedation or an induction of muscle relaxation.

The compositions include those suitable for oral, rectal and parenteral (including subcutaneous, intramuscular, and intravenous) administration, although the most suitable route will depend on the nature and severity of the condition being treated. The most preferred route of the present invention is the oral route. The compositions may be conveniently presented in unit dosage form, and prepared by any of the methods well known in the art of pharmacy.

20

The active compound can be combined with a pharmaceutical carrier according to conventional pharmaceutical compounding techniques. The carrier may take a wide variety of forms depending on the form of the preparation desired for administration, e.g. oral or parenteral (including intravenous injections or infusions). In preparing the compositions for oral dosage form any of the usual pharmaceutical media may be employed. Usual pharmaceutical media include, for example, water, glycols, oils, alcohols, flavoring agents, preservatives, coloring agents, and the like in the case of oral liquid preparations (such as for example, suspensions, solutions, emulsions and elixirs);

30

aerosols; or carriers such as starches, sugars, micro-crystalline cellulose, diluents, granulating agents, lubricants, binders, disintegrating agents and the like, in the case of oral solid preparations (such as for example, powders, capsules, and tablets) with the oral solid preparations being preferred over the oral liquid preparations.

Because of their ease of administration, tablets and capsules represent the most advantageous oral dosage unit form, in which case solid pharmaceutical carriers are employed. If desired, tablets may be coated by standard aqueous or nonaqueous techniques.

A suitable dosage range for use is from about 0.01 mg to about 100,00 mg total daily dose, given as a once daily administration or in divided doses if required.

The compounds of general formula (I) may be prepared according to the reaction shown in Scheme 1.

Scheme 1

where R<sub>1</sub> is as described above and Q is an appropriate leaving group consisting of dimethylamino, methylthio or methoxy. The reaction between 4-nitro-2H-pyrazol-3-ylamine (III) and appropriately substituted 1-(aryl) or (heteroaryl)-2-propen-1-one (II) is carried out in an

inert polar protic or aprotic solvent such as glacial acetic acid, ethanol, methanol, dimethylformamide or dimethylsulfoxide at a temperature ranging from 50° to 130°C. After elapsing several hours (reaction time), the solvent is removed and the residue obtained is partitioned between an aqueous solution of sodium bicarbonate and dichloromethane. The crude resulting from evaporating the organic layer to dryness may be purified by one of the following methods: (a) Silica gel chromatography using ethyl acetate or dichloromethane/methanol as eluent; and (b) Crystallization in a suitable solvent (for example, ethyl acetate, ethanol, methanol, etc.).

The intermediate of formula (II) when Q is dimethylamino may be obtained by reaction between the corresponding acetophenone and *N,N*-dimethylformamide dimethylacetal or Brederick's reagent (*tert*-butoxybis(dimethylamino)methane) as described by J. M. Domagala et al (J. Heterocyclic Chem., 26(4), 1147-58, 1989); and K. Sawada et al (Chem. Pharm. Bull., 49(7), 799-813, 2001). Specifically, when R<sub>1</sub> is a substituted aryl group, the reaction sequence leading to the intermediate of formula (II) is shown in Scheme 2, R<sub>5</sub>, R<sub>6</sub>, R<sub>7</sub> and n being as described above.

The intermediate 4-nitro-2H-pyrazol-3-ylamine (III) is obtained as described by M. E. C. Biffin et al. (J. Chem. Soc. (C) 2159-2162, 1968); M. E. C. Biffin et al. (Aust. J. Chem. 26, 1041-1047, 1967); and M. E. C. Biffin et al. (Tetrahedron Lett., 21, 2029-2031, 1967) following the reaction sequences shown in Scheme 3.

## Scheme 3

From the compounds of general formula (I) it is possible to obtain their pharmaceutically acceptable salts by treatment with the corresponding acids.

The applicants have discovered that the compounds of the present invention have a high affinity for  $\alpha_1$ - and  $\alpha_2$ -GABA<sub>A</sub> receptors as shown in Tables 1 and 2. These *in vitro* results are consistent with those *in vivo* results obtained in sedation-hypnosis tests (Table 3). In accordance with the results obtained, certain compounds of the present invention have surprisingly evidenced pharmacological activity both *in vitro* and *in vivo*, which has been similar to or higher than that of prior-art compounds. All these results support their use in diseases or conditions modulated by  $\alpha_1$ - and  $\alpha_2$ -GABA<sub>A</sub> receptors, such as insomnia or anesthesia, in which an induction of sleep, an induction of sedation or an induction of muscle relaxation are needed.

The pharmacological activity of the compounds of the present invention has been determined as shown below.

*Ligand-binding assays. Determination of the affinity of test compounds for  $\alpha_1$ - and  $\alpha_2$ -GABA<sub>A</sub> receptors.*

Male Sprague-Dawley rats weighing 200-250 g at the time of experiment were used. After decapitation of the animal, the cerebellum (tissue that mostly contains  $\alpha_1$ -GABA<sub>A</sub> receptor) and spinal cord (tissue that mostly contains  $\alpha_2$ -GABA<sub>A</sub> receptor) were removed. The membranes were prepared according to the method by J. Laméh et al. (Prog. Neuro-Psychopharmacol. Biol. Psychiatry, 24,

979-991, 2000). Once the tissues weighed, they were suspended in 50 mM Tris HCl buffer, pH 7.7, (1:40 v/v), homogenized and then centrifuged at 20000 g for 10 min at 7°C. The resulting pellet was resuspended under the same conditions and centrifuged again. The final pellet obtained was resuspended on a minimum volume and kept at -80°C overnight. On the next day, the process was repeated until the final pellet was resuspended at a ratio of 1:10 (v/v).

The affinity of the compounds was determined by competitive tests using radiolabeled flumazenil as ligand. The methods described by S. Arbilla et al. (Eur. J. Pharmacol., 130, 257-263, 1986); and Y. Wu et al. (Eur. J. Pharmacol., 278, 125-132, 1995) were used. The membranes containing the study receptors, flumazenil (radiolabeling at a final concentration of 1 nM) and ascending concentrations of test compounds (in a total volume of 500 µl in 50 mM [pH 7.4] Tris HCl buffer) were incubated. Simultaneously, the membranes were only incubated with the radiolabeled flumazenil (total binding, 100%) and in the presence of an elevated concentration of unradiolabeled flumazenil (non-specific binding, % estimate of radiolabeled ligand). The reactions started on adding the radiolabeled ligand followed by incubation for 60 minutes at 0°C. At the end of the incubation period, the tubes were filtered using a Brandel Mod. M-48R harvester and then washed three times with cold test buffer. The harvester was fitted with a GF/B filter that retained the membranes containing the receptors and the radiolabeled ligand which had been bound to the receptors. Then the filters were removed and left till dry. Once dried, the filters were cut, placed in vials with scintillation liquid and

left under stirring overnight. The next day the filters were counted using a Packard Mod. Tricarb scintillation counter.

5 For analysis of the results the percentage of specific binding for every concentration of test compound was calculated as follows:

$$\% \text{ specific binding} = (X - N / T - N) \times 100$$

10 where,

X: amount of bound ligand for every concentration of compound.

T: total binding, maximum amount bound to the radiolabeled ligand.

15 N: Non-specific binding, amount of radiolabeled ligand bound in a non-specific way irrespective of the receptor used.

Every concentrations of compound were tested in  
20 duplicate and their mean values were used to determine the experimental values of % specific binding versus the concentration of compound. The values thus attained were fitted to a equation for competitive assays (SigmaPlot, SPSS Inc.) and the IC<sub>50</sub> values (concentration of compound  
25 able to inhibit by 50% the specific binding) were calculated. Inhibition constants (K<sub>i</sub>) were calculated from the IC<sub>50</sub> values according to Cheng-Prusoff's formula (Y. Cheng y W. H. Prusoff, Biochem. Pharmacol., 22(23), 3099-3108, 1973). Alternatively, the affinity data for  
30 subunit  $\alpha_2$  are expressed as % inhibition at the concentrations of 10<sup>-5</sup>M and 10<sup>-7</sup>M. The results of these tests are given in Tables 1 and 2.

*In vivo* determination of predictive sedative-hypnotic action.

The *in vivo* effects of these compounds were assessed by a predictive sedation-hypnosis test in mice (D. J. Sanger et al., Eur. J. Pharmacol., 313, 35-42, 1996; and G. Griebel et al., Psychopharmacology, 146, 205-213, 1999).

Groups of 5-8 male CD1 mice, weighing 22-26 g at the time of test, were used. The test compounds were administered in single equimolecular intraperitoneal doses, suspended in 0.25% agar with one drop of Tween in a volume of 10 ml/kg. Control animals received the vehicle alone. Using an Actisystem DAS16 (Panlab, S.L., Spain) the crossings (number of counts) were recorded for each mouse at 5-min intervals during a period of 30 minutes after dosing. The inhibition percentage of crossings of treated animals versus control animals (the first 5 min were discarded) was calculated. The results of this test are given in Table 3.
