ABSTRACT

An air-permeable composite fabric is provided. The composite fabric has an inner fabric layer, an outer fabric layer, and an intermediate vapor barrier. The vapor barrier is selected from adhesive material and an adhesive/membrane combination designed so the composite fabric has a level of air permeability to allow air flow between the first fabric layer and the second fabric layer and a variable level of water vapor diffusion resistance that decreases as air speed impinging on the composite fabric increases.

WATER VAPOR DIFFUSION RESISTANCE (g/m²)

WIND SPEED THRU FABRIC (miles/hr.)
AIR-PERMEABLE COMPOSITE FABRIC

[0001] This application is a continuation of and claims the benefit of U.S. application Ser. No. 11/434,017, filed on May 15, 2006, which is a continuation of U.S. application Ser. No. 10/650,098, filed Aug. 25, 2003, now pending, which is a continuation of U.S. application Ser. No. 09/378,344, filed Aug. 20, 1999, now abandoned, which claims the benefit of U.S. Provisional Application No. 60/098,254, filed Aug. 28, 1998, now expired. U.S. application Ser. No. 10/650,098, filed Aug. 25, 2003, now pending, is also a continuation of U.S. Ser. No. 10/341,309, filed Jan. 13, 2003, now abandoned, which is a continuation of U.S. application Ser. No. 09/863,852, filed May 23, 2001, now abandoned, which is a divisional of U.S. application Ser. No. 09/378,344, filed Aug. 20, 1999, now abandoned. The contents of the prior applications are considered part of (and are incorporated by reference in) the disclosure of this application.

BACKGROUND

[0002] This invention relates to a fabric material, and more particularly, to a composite fabric having controlled wind permeability.

[0003] Conventional composite fabrics are designed to be fully wind resistant. By way of example, reference is made to U.S. Pat. Nos. 5,204,156; 5,268,212; and 5,364,678, all entitled “Windproof and Water Resistant Composite Fabric With Barrier Layer,” and which describe a drapable, stretchable, windproof, water resistant and water vapor-permeable composite fabric. This composite fabric includes an inner fabric layer 13A, an outer fabric layer 13B, and a barrier or membrane layer 17A (see FIG. 1). The barrier or membrane layer is constructed to prevent air and water from passing through the fabric layers. Testing has shown that the amount of air flowing through such a composite fabric is on the order of no more than 1 ft³/ft²/min.

SUMMARY

[0007] Accordingly, it is desirable to provide an improved windproof, water vapor permeable fabric which eliminates the problems associated with prior art fabrics.

[0008] Generally speaking, in accordance with the invention, a wind resistant and water vapor permeable composite fabric is provided. The composite fabric includes an inner fabric layer, an outer fabric layer, and an intermediate vapor barrier. The vapor barrier is selected from adhesive material and an adhesive/membrane combination designed so the composite fabric has a level of air permeability to allow air flow between the first fabric layer and the second fabric layer and a variable level of water vapor diffusion resistance that decreases as air speed impinging on the composite fabric increases.

[0009] The adhesive may be a continuous film which is mechanically altered by means of crushing, stretching and the like to enhance air permeability or a discontinuous film which inherently enhances air permeability. The adhesive and/or the membrane may be applied directly to the fabric surface of one or both of the fabric layers or may be applied by means of transfer coating from release paper.

[0010] In one example, the adhesive functions as a vapor barrier and is disposed between the two fabric layers. The adhesive may be in the form of a foam. One or more rollers may be used to apply pressure to the fabric in order to selectively adjust the air permeability characteristics thereof.

[0011] In a second embodiment, the vapor barrier comprises a membrane made from polyurethane, polyamide, polytetrafluoroethylene or polyester, or a combination thereof, which is applied between the two fabric layers 15 and adhered thereto with an adhesive. The fabric composite undergoes mechanical processing, such as controlled stretching, in order to achieve a desired level of air permeability.

[0012] According to one aspect of the invention, an air-permeable composite fabric comprises a first fabric layer, a second fabric layer, and an intermediate, air-permeable vapor barrier disposed between and bonded to the first and second fabric layers. The intermediate, air-permeable barrier layer is selected from the group consisting of: a foamed adhesive in the form of a discontinuous film, an adhesive in the form of a continuous film mechanically altered by one of crushing and stretching, and a membrane disposed between and adhered to the first fabric layer and the second fabric layer with an adhesive and mechanically altered by stretching. The intermediate, air-permeable vapor barrier layer has a level of air permeability to allow air flow between the first and second fabric layers, and the intermediate, air-permeable vapor barrier layer has a variable level of water vapor diffusion resistance that substantially decreases as air speed of moving air impinging on the fabric increases.

[0013] Preferred embodiments of this aspect of the invention may include one or more of the following additional features. The adhesive is selected from the group consisting of polyurethane, acrylics, polyamides, polyessters and combinations thereof. At least one of the first and second fabric layers is rendered hydrophobic. At least one of the first and second fabric layers has a raised surface. The intermediate, air-permeable vapor barrier comprises an adhesive selected from the group consisting of: an adhesive in the form of a mechanically altered continuous film and a foamed adhesive.
in the form of a discontinuous film. The vapor barrier is exclusively foamed adhesive in the form of a discontinuous film. The intermediate, air-permeable vapor barrier comprises the membrane disposed between the first and second fabric layers and adhered thereto with an adhesive and mechanically altered by stretching, the composite fabric having undergone mechanical processing. The membrane is made from a material selected from the group consisting of polyurethane, polyamide, polytetrafluoroethylene, polyester and combinations thereof. The mechanical processing comprises controlled stretching. The adhesive is selected from the group consisting of polyurethane, acrylics, polyamides, polyesters and combinations thereof.

[0014] According to another aspect of the invention, a method of forming an air-permeable composite fabric comprising the steps of: selecting a vapor barrier from the group consisting of a membrane and an adhesive, disposing the vapor barrier between a first fabric layer and a second fabric layer in order to produce the composite fabric, and mechanically processing the composite fabric of such that the intermediate, air-permeable vapor barrier layer has a level of air permeability to allow air flow between the first fabric layer and the second fabric layer and the intermediate, air-permeable vapor barrier layer has a variable level of water vapor diffusion resistance that decreases as air speed impinging on the composite fabric increases.

[0015] Preferred embodiments of this aspect of the invention may include one or more of the following additional features. The vapor barrier is a membrane, and the step of mechanical processing comprises controlled stretching of the composite fabric. The vapor barrier is an adhesive, and the step of mechanical processing comprises applying pressure to the composite fabric. The method comprises passing the composite fabric through a plurality of rollers while applying pressure. The method comprises passing the composite fabric through a plurality of heated rollers while applying pressure. The method comprises passing the composite fabric through the rollers at variable controlled speeds. Preferably, the adhesive is foamed. The method comprises disposing the adhesive between the first fabric layer and the second fabric layer by transfer coating using release paper. The method comprises disposing the vapor barrier between the first fabric layer and the second fabric layer as a continuous film of adhesive. The method comprises disposing the vapor barrier between the first fabric layer and the second fabric layer as a discontinuous film of adhesive. The method comprises disposing the vapor barrier between the first fabric layer and the second fabric layer as a film of adhesive using release paper. The method comprises disposing the vapor barrier between the first fabric layer and the second fabric layer by applying the adhesive directly to at least one of the first fabric layer and the second fabric layer.

[0016] Accordingly, it is an object of the invention to provide an improved windproof composite fabric, whose wind resistance may be varied.

[0017] Still another object of the invention is to provide a composite fabric which is water resistant.

[0018] A further object of the invention is to provide an air-permeable composite fabric.

[0019] Yet another object of the invention is to provide a composite fabric having a moisture vapor transmission rate which substantially increases as air speed impinging on the fabric increases.

Still other objects and advantages of the invention will in part be obvious and will in part be apparent from the following description.

The invention accordingly comprises the several steps and the relation of one or more steps with respect to each of the others, and the fabric possessing the features, properties and construction of elements which are exemplified in the following detailed disclosure, and the scope of the invention is indicated in the claims.

DESCRIPTION OF DRAWINGS

For a fuller understanding of the invention, reference is made to the following description, taken in connection with the accompanying drawings, in which:

[0029] FIG. 1 is a front view in cross-section illustrating a composite fabric of the prior art;

[0030] FIG. 2 is a front view in cross-section illustrating a composite fabric made in accordance with the invention;

[0031] FIG. 3A is a graph which shows the change in moisture vapor transmission as a function of air permeability in the inventive composite fabric;

[0032] FIG. 3B is a graph showing the change in air permeability as a function of thermal resistance in the inventive composite fabric;

[0033] FIG. 4A is a front view in cross-section showing formation of a second embodiment of the composite fabric of the invention;

[0034] FIG. 4B shows the effects of controlled stretching on the composite fabric depicted in FIG. 4A;

[0035] FIG. 5 is a front view in cross-section showing the formation of a third embodiment of the inventive composite fabric;

[0036] FIG. 6 is a front elevational view in cross-section showing the formation of a fourth embodiment of the inventive composite fabric;

[0037] FIG. 7 is a graph showing the relationship of water vapor resistance as a function of wind speed impinging on the inventive fabric as compared to prior art fabrics.

LIKE reference symbols in the various drawings indicate like elements.

DETAILED DESCRIPTION

Referring first to FIG. 2, a first embodiment of the inventive composite fabric, generally indicated at 11, is shown. Fabric 11 comprises first and second fabric layers 13 and 15, and a barrier 17 disposed therebetween. Fabric 11 has variable water vapor permeability, as discussed below. In this embodiment, the barrier 17 consists of an adhesive material. Adhesive 17 may, in one form, be applied by means of transfer coating from release paper at between 0.25 oz/yd² and 2.5 oz/yd². Each of layers 13 and 15 may be treated or modified, as described in U.S. Pat. Nos. 5,204,156; 5,268,212; and 5,364,678, including rendering the layers hydrophilic, providing the layers with a raised surface, treating the layers to be water repellant, etc.

[0034] Fabric 11 is formed to any specific controlled wind resistant performance level, as discussed below. As shown, air which impinges upon fabric 11 is partially deflected away from the barrier 17 and partially penetrates as well through the barrier 17.

[0035] In the absence of moving air, water vapor/moisture from the skin can only transfer through the fabric by means of an absorption/adsorption phenomenon leading to excess heat...
buildup and moisture. When fabric allows some air to pass through the barrier, it helps in transferring high moisture levels and thus make the wearer more comfortable.

Importantly, as wind speed increases, more air flows through the barrier, allowing more vapor to be dissipated. Thus, the composite fabric of the invention has a relatively high water vapor permeability in moving air, and has substantially reduced resistance to vapor permeability with an increase in air flow. The reduction in wind resistance or increase in air permeability will not cause any significant loss of the thermal insulative properties, as shown in the graphs of FIGS. 3A and 3B now discussed, because the actual amount of air penetrating the barrier is minimal.

The graph of FIG. 3A illustrates that for any increase in air permeability of the inventive fabric, there is a corresponding decrease in evaporation pressure resistance. The graph of FIG. 3B shows that for any increase in air permeability of the inventive fabric, there will be a corresponding decrease in thermal resistance of the composite fabric. As can be appreciated from viewing the graphs, there is a substantial difference between the magnitude of change in evaporation pressure resistance and thermal resistance. Evaporation pressure resistance drops far more rapidly than thermal resistance for the same amount of change in air permeability of the composite fabric. Thus, when there is a small increase in air permeability of the composite fabric, the evaporative pressure resistance reduces significantly.

As evaporation pressure resistance decreases, more moisture can be transported across the composite fabric, and thus, the loss in thermal resistance which defines the warmth of the fabric is not affected significantly.

FIG. 4A describes a second embodiment of the inventive composite fabric, which is generally indicated at 21. Composite fabric 21 includes first and second fabric layers 23 and 25, a barrier that in this case is an intermediate membrane 27, and an adhesive 29 on both sides of membrane 27 for adhering membrane 27 to fabric layers 23 and 25. Adhesive 29 may, in one form, be applied by means of transfer coating from release paper at a thickness of between 0.25 oz/yd² and 2.5 oz/yd². Membrane 27 is made from polyurethane, polytetrafluoroethylene or polyester. Membrane 27 may be applied by means of transfer coating from release paper at a thickness of between 0.003 in. to 0.010 in., or directly on the fabric surfaces at a thickness of between 0.0003 in. and 0.010 in.

As shown in FIG. 4B, composite fabric 21 having a width, W, is subjected to controlled stretching to produce a composite having a width, W’, with a desired specific level of air permeability.

Referring now to FIG. 5, a third embodiment of the invention as a composite fabric is shown and generally indicated at 31. Composite fabric 31 includes fabric layers 33 and 35, and a barrier consisting of an intermediate adhesive 37. The adhesive is chosen from a polyurethane, polyester, acrylic and polyamide. Here, adhesive 37 is applied as a foam at between about 0.3 oz/yd² and 10 oz/yd². The foam density (mixing air with adhesive) and the amount of adhesive applied are selected depending on the desired air permeability of the composite. Composite fabric 31 is prepared by first applying foam adhesive 37 on one of the opposite surfaces of fabric layers 33 and 35. Once applied, the other fabric layer is put over the adhesive in order to produce the inventive fabric composite. Composite 31 is then mechanically processed by means of a pair of rollers 39, which apply pressure thereto in an amount between about 10 lbs./in² and 150 lbs./in² in order to produce a composite having a specific level of air permeability.

Referring now to FIG. 6, a further embodiment of the inventive composite fabric is shown. Composite fabric 41 comprises fabric layers 43 and 45 and a barrier formed of an intermediate adhesive 47. Air permeability is controlled by applying the adhesive on the fabric and then using some type of mechanical processing, such as treatment with rollers 19, in order to create the desired levels of air permeability.

Still referring to FIG. 6, adhesive 47 may, in one form, be applied by means of a release paper. The adhesive is first placed on the release paper at between about 0.25 oz./yd² and 2.5 oz./yd², after which one of the fabric layers is put on top thereof in order for bonding to occur. Then, the release paper is stripped from the fabric and the second fabric layer is applied to the other side of the adhesive. The composite then undergoes mechanical processing by rollers 49 (which may be heated to a temperature of between about 100° F. and 375° F.), which apply pressure to the composite fabric. As can be appreciated, changing any mechanical parameter (roller temperature, pressure applied, and speed of the fabric through the rollers) helps change the air permeability characteristics of the composite fabric.

Alternatively, and still referring to FIG. 6, adhesive 47 may be directly applied to one of fabric layers 43 and 45 (at 0.25 oz./yd² to 2.5 oz./yd²) without the use of release paper. As before, the composite fabric will undergo mechanical processing in order to achieve a desired air permeability performance.

FIG. 7 describes the advantages of the present invention over the prior art. In this figure, lines A and B show the water vapor diffusion resistance for two prior art fabrics (GORE WINDSTOPPER® fabric using GORE-TEX® PTFE membrane from WL Gore & Associates, Inc. (Newark, Del.) and ET551 laminate with PTFE from Tetratec Corporation (Feasterville, Pa.)). As seen in FIG. 7, the diffusion resistance for these prior art fabrics is substantially constant. However, in the materials identified by lines C, D, E and F, corresponding respectively to various air permeability level samples (high to low), the vapor diffusion resistance decreases dramatically with increased wind speed through the fabric.

It will thus be seen that the objects set forth above, among those made apparent from the preceding description, are efficiently attained, and, since certain changes may be made in carrying out the above method and in the fabrication construction set forth without departing from the spirit and scope of the invention, it is intended that all matter contained in the above description and shown in the drawings shall be interpreted as merely illustrative, and should not be considered limiting.

The following claims are intended to cover all of the generic and specific features of the invention described herein, and all statements of the scope of the invention which might be said to fall therebetween.

What is claimed is:

1. An air-permeable composite fabric comprising:
   a. first fabric layer;
   b. a second fabric layer; and
   an intermediate, air-permeable vapor barrier disposed between and bonded to said first fabric layer and said second fabric layer, wherein:
said intermediate, air-permeable barrier layer is a continuous film mechanically altered by crushing the composite fabric between a plurality of rollers; said intermediate, air-permeable vapor barrier layer has a level of air permeability to allow air flow between said first fabric layer and said second fabric layer, and said intermediate, air-permeable vapor barrier layer has a variable level of water vapor diffusion resistance that substantially decreases as air speed of moving air impinging on said composite fabric increases.

2. The air-permeable composite fabric of claim 1, wherein said membrane is made from a material selected from the group consisting of polyurethane, polyamide, polytetrafluoroethylene, polyester and combinations thereof.

3. The air-permeable composite fabric of claim 1, wherein said intermediate, air-permeable barrier layer is a continuous film mechanically altered by crushing the composite fabric between a plurality of rollers that are heated.

4. The air-permeable composite fabric of claim 3, wherein said plurality of rollers are heated to a temperature of between about 100°F and 375°F.

5. The air-permeable composite fabric of claim 1, wherein at least one of said first fabric layer and said second fabric layer has a raised surface.

6. The air-permeable composite fabric of claim 1, wherein said intermediate, air-permeable vapor barrier is adhered to said first fabric layer and said second fabric layer with an adhesive.

7. The air-permeable composite fabric of claim 6, wherein said adhesive is selected from the group consisting of polyurethane, acrylics, polyamides, polyesters and combinations thereof.
