INHIBITORS OF MEK

RELATED APPLICATION

[0001] This application claims priority to U.S. Provisional Application No. 60/885,849 filed on January 19, 2007.

BACKGROUND OF THE INVENTION

[0002] Cell signaling pathways play an important role in cell growth, proliferation and differentiation. In normal cell growth, growth factors, through receptor activation (e.g. PDGF or EGF), activate MAP kinase pathways. The Ras/Raf kinase pathway is one of the most important and most well understood MAP kinase pathways involved in normal and uncontrolled cell growth. Active GTP-bound Ras leads to the activation of a cascade of serine/threonine kinases. One of the several groups of kinases known to require GTP-bound Ras for their activation is the Raf family. Upon activation, Raf phosphorylates “mitogen-activated ERK activating kinases” (MEK) - 1 and MEK2.

[0003] Some cancers contain mutations which result in the continuous activation of this pathway due to continuous production of growth factors. Other mutations can lead to defects in the deactivation of the activated GTP-bound Ras complex, again resulting in activation of the MAP kinase pathway. Mutated, oncogenic forms of Ras are found in 50% of colon and >90% pancreatic cancers as well as many others types of cancers. Recently, bRaf mutations have been identified in more than 60% of malignant melanoma.

[0004] These mutations in bRaf result in a constitutively active MAP kinase cascade. Studies of primary tumor samples and cell lines have also shown constitutive or over activation of the MAP kinase pathway in cancers of pancreas, colon, lung, ovary and kidney. Hence, there is a strong correlation between cancers and an overactive MAP kinase pathway resulting from genetic mutations.

[0005] As constitutive or over activation of MAP kinase cascade plays a pivotal role in cell proliferation and differentiation, inhibition of this pathway is believed to be beneficial in hyperproliferative diseases. MEK is a key player in this pathway as it is downstream of Ras and Raf. Additionally, it is an attractive therapeutic target because the only known substrates for MEK phosphorylation are the MAP kinases, ERK1 and 2.

[0006] Inhibition of MEK has been shown to have potential therapeutic benefit in several studies. For example, small molecule MEK inhibitors have been shown to inhibit human tumor growth in nude mouse xenografts, block static allodynia in animals and inhibit growth of acute myeloid leukemia cells.

[0007] Thus, MEK1 and MEK2 are validated and accepted targets for anti-proliferative therapies, even when the oncogenic mutation does not affect MEK structure or expression.

[0008] The MEK cascade has also been implicated in inflammatory diseases and disorders. This includes both acute and chronic inflammation disorders. Examples of such disorders are allergic contact dermatitis, rheumatoid arthritis, osteoarthritis, inflammatory bowel diseases, chronic obstructive pulmonary disorder, psoriasis, multiple sclerosis, asthma, diseases and disorders related to diabetic complications, and inflammatory complications of the cardiovascular system such as acute coronary syndrome. Among inflammatory bowel diseases are Crohn’s disease and ulcerative colitis.

Certain compounds of the present invention may have asymmetric centers and therefore exist in different enantiomeric forms. All optical isomers and stereoisomers of the compounds of the present invention, and mixtures thereof, are considered to be within the scope of the invention. With respect to the compounds of the present invention, the invention includes the use of a racemate, one or more enantiomeric forms, one or more diastereomeric forms, or mixtures thereof. The compounds of the present invention may also exist as tautomers. This invention relates to the use of all such tautomers and mixtures thereof. The compounds of the present invention may also exist in different polymorphic states. This invention relates to the use of all such polymorphic states and mixtures thereof.

The subject invention also includes isotopically-labeled compounds, which are identical to those recited in the present invention, but for the fact that one or more atoms are replaced by an atom having an atomic mass or mass number different from the atomic mass or mass number usually found in nature. Examples of isotopes that can be incorporated into compounds of the invention include isotopes of hydrogen, carbon, nitrogen, oxygen, phosphorous, sulfur, fluorine and chlorine, such as ²H, ³H, ¹³C, ¹⁴C, ¹⁵N, ¹⁶O, ¹⁷O, ³¹P, ³²P, ³⁵S, ³⁵Cl, ³⁷Cl, ³⁸Cl, ¹⁸F, and ³⁶Cl, respectively. Compounds of the present invention, pharmaceutically acceptable salt, ester, prodrug, solvate, hydrate or derivative thereof which contain the aforementioned isotopes and/or other isotopes of other atoms are within the scope of this invention. Certain isotopically-labeled compounds of the present invention, for example those into which radioactive isotopes such as ³¹H and ¹⁴C are incorporated, are useful in drug and/or substrate tissue distribution assays.
[0072] Tritiated, i.e., $^3$H and carbon-14, i.e., $^{14}$C, isotopes are particularly preferred for their ease of preparation and detectability. Further, substitution with heavier isotopes such as deuterium, i.e., $^2$H, can afford certain therapeutic advantages resulting from greater metabolic stability, for example increased in vivo half-life or reduced dosage requirements and, hence, may be preferred in some circumstances. Isotopically labeled compound of the present invention, pharmaceutically acceptable salt, ester, prodrug, solvate, hydrate or derivative thereof can generally be prepared by carrying out procedures disclosed in the Schemes and/or in the Examples and Preparations below, by substituting a readily available isotopically labeled reagent for a non-isotopically labeled reagent.

[0073] This invention also encompasses prodrugs of compounds described herein and methods of treating disorders. For example, the invention provides for methods of treating proliferative disorders, or abnormal cell growth, by administering prodrugs of compounds of the present invention. The prodrugs of compounds of the invention can be administered as pharmaceutical compositions. Compounds of the present invention having free amino, amido, hydroxy or carboxylic groups can be converted into prodrugs.

[0074] In some embodiments, prodrugs include compounds wherein an amino acid residue, or a polypeptide chain of two or more (e.g., two, three or four) amino acid residues is covalently joined through an amide or ester bond to a free amino, hydroxy or carboxylic acid group of compounds of the present invention. The amino acid residues include but are not limited to the 20 naturally occurring amino acids commonly designated by three letter symbols and also includes 4-hydroxyproline, hydroxylysine, demosine, isodemosine, 3-methylhistidine, norvaline, beta-alanine, gamma-aminobutyric acid, cirtulline, homocysteine, homoserine, ornithine and methionine sulfone. Additional types of prodrugs are also encompassed.

[0075] For instance, free carboxyl groups can be derivatized as amides or alkyl esters. Free hydroxy groups may be derivatized using groups including but not limited to hemiacetates, phosphate esters, dimethylaminoacetates, and phosphoryloxyhemioxyxycarbonyls, as outlined in Advanced Drug Delivery Reviews 1996, 19, 115. Carbamate prodrugs of hydroxy and amino groups are also included, as are carbonate prodrugs, sulfonate esters and sulfate esters of hydroxy groups.

[0076] Derivatization of hydroxy groups as (acyloxy) methyl and (acyloxy) ethyl ethers wherein the acyl group may be an alkyl ester, optionally substituted with groups including but not limited to ether, amine and carboxylic acid functionalities, or where the acyl group is an amino acid ester as described above, are also encompassed. Prodrugs of this type are described in J. Med. Chem. 1996, 39, 10. Free amines can also be derivatized as amides, sulfonamides or phosphonamides. All of these prodrug moieties may incorporate groups including but not limited to ether, amine and carboxylic acid functionalities.

[0077] It is to be understood that in instances where two or more radicals are used in succession to define a substituent attached to a structure, the first named radical is considered to be terminal and the last named radical is considered to be attached to the structure in question. Thus, for example, the radical arylalkyl is attached to the structure in question by the alkyl group.

The compounds of the present invention may have asymmetric carbon atoms. Diastereomeric mixtures can be separated into their individual diastereomers on the basis of their physical chemical differences by methods known to those skilled in the art, for example, by chromatography or fractional crystallization. Enantiomers can be separated by converting the enantiomer mixture into a diastereomeric mixture by reaction with an appropriate optically active compound (e.g., alcohol), separating the diastereomers and converting (e.g., hydrolyzing) the individual diastereomers to the corresponding pure enantiomers. All such isomers, including diastereomeric mixtures and pure enantiomers are considered as part of the invention.

The activity of the compounds of the present invention may be determined by the following procedure, as well as the procedure described in the examples below. N-terminal 6 His-tagged, constitutively active MEK1 (2-393) is expressed in E. coli and protein is purified by conventional methods (Ahn et al. Science 1994, 265, 966-970). The activity of MEK1 is assessed by measuring the incorporation of \( \gamma^{32}\text{P}\)-phosphate from \( \gamma^{32}\text{P}\)-ATP onto N-terminal His tagged ERK2, which is expressed in E. coli and is purified by conventional methods, in the presence of MEK1. The assay is carried out in 96-well polypropylene plate. The incubation mixture (100, \( \mu \text{L} \)) comprises of 25 mM Hepes, pH 7.4, 10 mM MgCl\(_2\), 5 mM \( \beta\)-glycerolphosphate, 100 \( \mu \text{M} \) Na-orthovanadate, 5 \( \mu \text{M} \) DTT, 5 \( \mu \text{M} \) MEK1, and 1 \( \mu \text{M} \) ERK2. Inhibitors are suspended in DMSO, and all reactions, including controls are performed at a final concentration of 1% DMSO. Reactions are initiated by the addition of 10 \( \mu \text{M} \) ATP (with 0.5 \( \mu \text{Ci} \) \( \gamma^{32}\text{P}\)-ATP/well) and incubated at ambient temperature for 45 minutes. Equal volume of 25% TCA is added to stop the reaction and precipitate the proteins. Precipitated proteins are trapped onto glass fiber B filter plates, and excess labeled ATP washed off using a Tomtec MACH III harvester. Plates are allowed to air-dry prior to adding 30 \( \mu \text{L} \)/well of Packard Microscint 20, and plates are counted using a Packard TopCount.

Administration of the compounds of the present invention (hereinafter the “active compound(s)”) can be effected by any method that enables delivery of the compounds to the site of action. These methods include oral routes, intraduodenal routes, parenteral injection (including intravenous, subcutaneous, intramuscular, intravascular or infusion), topical, and rectal administration.

The amount of the active compound administered will be dependent on the mammal being treated, the severity of the disorder or condition, the rate of administration, the disposition of the compound and the discretion of the prescribing physician. However, an effective dosage is in the range of about 0.001 to about 100 mg per kg body weight per day, preferably about 1 to about 35 mg/kg/day, in single or divided doses. For a 70 kg human, this would amount to about 0.05 to 7 g/day, preferably about 0.05 to about 2.5 g/day. In some instances, dosage levels below the lower limit of the aforesaid range may be more than adequate, while in other cases still larger doses may be employed without causing any harmful side effect, e.g. by dividing such larger doses into several smaller doses for administration throughout the day.

The active compound may be applied as a sole therapy or may involve one or more other anti-tumor substances, for example those selected from, mitotic inhibitors, for example vinblastine; alkylating agents, for example cis-platin, carboplatin and cyclophosphamide; anti-metabolites, for example 5-fluourouracil, cytosine arabinoside and hydroxyurea, or, for example, one of the preferred anti-metabolites disclosed in European Patent Application No. 239362 such as N-(5-[N-(3, 4-dihydro-2-methyl-4- oxoquinazolin-6-ylmethyl)-N- methylamino]-2-thenyl)-L-glutamic acid; growth factor inhibitors; cell cycle inhibitors; intercalating antibiotics, for example Adriamycin and bleomycin; enzymes, for example, interferon; and anti-hormones, for
example anti-estrogens such as Nolvadex™ (tamoxifen) or, for example anti-androgens such as Casodex™ (4’-cyano-3’-(4-fluorophenylsulphonyl)-2-hydroxy-2-methyl-3’- (trifluoromethyl) propiunamide). Such conjoint treatment may be achieved by way of the simultaneous, sequential or separate dosing of the individual components of treatment.

[00122] The pharmaceutical composition may, for example, be in a form suitable for oral administration as a tablet, capsule, pill, powder, sustained release formulations, solution, suspension, for parenteral injection as a sterile solution, suspension or emulsion, for topical administration as an ointment or cream or for rectal administration as a suppository. The pharmaceutical composition may be in unit dosage forms suitable for single administration of precise dosages. The pharmaceutical composition will include a conventional pharmaceutical carrier or excipient and a compound according to the invention as an active ingredient. In addition, it may include other medicinal or pharmaceutical agents, carriers, adjuvants, etc.

[00123] Exemplary parenteral administration forms include solutions or suspensions of active compounds in sterile aqueous solutions, for example, aqueous propylene glycol or dextrose solutions. Such dosage forms can be suitably buffered, if desired.

[00124] Suitable pharmaceutical carriers include inert diluents or fillers, water and various organic solvents. The pharmaceutical compositions may, if desired, contain additional ingredients such as flavorings, binders, excipients and the like. Thus for oral administration, tablets containing various excipients, such as citric acid may be employed together with various disintegrants such as starch, alginic acid and certain complex silicates and with binding agents such as sucrose, gelatin and acacia. Additionally, lubricating agents such as magnesium stearate, sodium lauryl sulphate and talc are often useful for tableting purposes. Solid compositions of a similar type may also be employed in soft and hard filled gelatin capsules. Preferred materials, therefore, include lactose or milk sugar and high molecular weight polyethylene glycols. When aqueous suspensions or elixirs are desired for oral administration the active compound therein may be combined with various sweetening or flavoring agents, coloring matters or dyes and, if desired, emulsifying agents or suspending agents, together with diluents such as water, ethanol, propylene glycol, glycerin, or combinations thereof.

[00125] Methods of preparing various pharmaceutical compositions with a specific amount of active compound are known, or will be apparent, to those skilled in this art. For examples, see Remington's Pharmaceutical Sciences, Mack Publishing Company, Ester, Pa., 18th Edition (1990).

[00126] In still another aspect, the present invention provides kits for the treatment of disorders, such as the ones described herein. These kits comprise a compound or compounds described herein in a container and, optionally, instructions teaching the use of the kit according to the various methods and approaches described herein. Such kits may also include information, such as scientific literature references, package insert materials, clinical trial results, and/or summaries of these and the like, which indicate or establish the activities and/or advantages of the composition, and/or which describe dosing, administration, side effects, drug interactions, or other information useful to the health care provider. Such information may be based on the results of various studies, for example, studies using experimental animals involving in vivo models and studies based on human clinical trials. Kits described herein can be provided, marketed and/or promoted to health providers, including physicians, nurses, pharmacists, formulary officials, and the like. Kits may also, in some embodiments, be marketed directly to the consumer.
The examples and preparations provided below further illustrate and exemplify the compounds of the present invention and methods of preparing such compounds. It is to be understood that the scope of the present invention is not limited in any way by the scope of the following examples and preparations. In the following examples molecules with a single chiral center, unless otherwise noted, exist as a racemic mixture. Those molecules with two or more chiral centers, unless otherwise noted, exist as a racemic mixture of diastereomers. Single enantiomers/diastereomers may be obtained by methods known to those skilled in the art.

\[ \text{Chemical Structure} \]

5  [00375] This compound is synthesized according to example 35 (step A through C) starting from 3-(4-bromo-2-fluorophenyl)-4-fluoro-8-methyl-1H-imidazo[4,5-g]quinolin-2(3H)-one (example 38).

Example 40: Biological activity

Generation of IC50 Data

[00376] Materials and preparation of reagents: Human GST-MEK1 and the constitutively 5 active allele GST-MEK1\textsuperscript{CA} (harboring the mutations Ser218Asp and Ser222Asp) can be subcloned into the yeast expression vector pGEM4Z (Promega, Madison, WI) from the wild type human MEK1 cDNA. GST-MEK1CA was expressed in *Escherichia coli* and can be partially purified using Glutathione Sepharose 4B affinity resin (Amersham Pharmacia Biotech, Piscataway, NJ). The ERK2 allele can be subcloned from MAPK2/Erk2 cDNA (wild type) in 10 pUSEamp (Upstate Biotechnology, Inc., Waltham, MA) into the vector pET21a (Novagen, Madison, WI) resulting in an N-terminal histidine-tagged mouse ERK2 allele. ERK2 can be expressed and purified to homogeneity [Zhang, 1993 #33]. Myelin basic protein (MBP) can be purchased from Gibco BRL (Rockville, MD). EasyTides adenosine 5'-triphosphate (ATP) ([γ-33P]) (NEN Perkin Elmer, Wellesley, MA) is the source of radiolabel for all kinase reactions. Activated Raf-1 (truncated) and activated MAPK/kinase 2/ERK2 can be purchased from Upstate, Inc. (Lake Placid, NY).  4-20% Criterion Precast gels can be purchased from Bio-Rad (Hercules, CA).

[00377] Determination of enzymatic activity: Compounds are diluted from dimethylsulfoxide (DMSO) stocks into 1xHMINDE (20 mM HEPES pH 7.2, 1 mM MgCl\textsubscript{2}, 100 mM NaCl, 1.25 mM DTT, 0.2 mM EDTA). A typical 25-microliter assay contained 0.002 nanomoles MEK1\textsuperscript{CA}, 0.02 nanomoles ERK2, 0.25 nanomoles MBP, 0.25 nanomoles unlabeled ATP, and 0.1 µCi [γ-33P] ATP. The screening assay essentially comprises four additions. Five µl of diluted compound are dispensed to 96-well assay plates. Ten µl of 2.5x enzyme cocktail (MEK1\textsuperscript{CA} and ERK2 only) are then added to each well followed by a preincubation for 30 minutes at ambient temperature. Ten µl of 2.5x substrate cocktail (labeled and unlabeled ATP plus MBP) are then added, followed by incubation for 60 minutes at ambient temperature. Finally, 100 µl of 10% trichloroacetic acid (TCA) are added and incubated for 30 minutes at room temperature to halt the reaction and precipitate radiolabeled protein products. Reaction products are harvested on glass fiber 96 well filter plates prewetted with water and 1% pyrophosphate. The filter plate is then washed 5 times with water. Water is displaced by absolute ethanol and the plate is allowed to air dry for 30 minutes at room temperature. A back seal is applied manually and 40 µl of
scintillation cocktail are dispensed to each well. A top seal is applied and the plate is counted in the TopCount for two seconds per well.

[00378] A truncated version of MEK that requires activation by Raf kinase can be used.

Generation of EC50 Data

[00379] Effects of compounds in the cell can be determined by Western blotting for phosphorylated ERK. MDA-MB-231 breast cancer cells are plated in a 48 well plate at 20,000 cells per well and are grown in a 37°C humidified CO2 incubator. The following day, the growth media (DMEM + 10% fetal bovine serum) is removed and replaced with starve media (DMEM + 0.1% fetal bovine serum). Cells are incubated in the starve media for sixteen hours and then treated with a range of compound concentrations for thirty minutes.

[00380] After incubation with compound, cells are stimulated with 100ng/ml EGF for five minutes. The cells are then lysed and analyzed by Western blot using a monoclonal antibody raised to phosphorylated ERK. The signal is amplified using a secondary antibody conjugated to a near-IR dye and detected on a Licor Odyssey scanner. The intensity of signal is quantitated and this data was used to generate dose response curves and EC50 calculations.
