Flushable manifold for diaphragm protected components.

A flushable manifold for diaphragm protected components of a pressure transducer for sensing a flow of fluid comprises a housing having a recess, a diaphragm of flexible material over and closing the recess and fluid inlet and outlet passages on opposite sides of the recess. To facilitate cleaning the manifold of fluid, at least one channel is formed in the housing within the recess in communication with the inlet and extending toward peripheral side areas of the recess to direct flushing media introduced at the inlet across all of the surfaces of the manifold to thoroughly clean the same.
Background of the Invention

The present invention relates to manifolds for diaphragm protected components which may readily be flushed of fluid of one type in preparation for receiving fluid of another type.

Pressure transducers are often used in spray coating systems to sense pressure of paint in a supply line and to generate an indication of system failure in the absence of pressure. Such transducers conventionally comprise a recess in a housing and a diaphragm of flexible material sealed with the housing over and around the recess. Inlet and outlet passages communicate with opposite sides of the recess to form a manifold with the housing and diaphragm and means, such as a micro-switch, senses outward deflection of the diaphragm in response to pressure of paint in the manifold.

For rapid color changes on high volume production lines, it is necessary that system components be flushed by flushing media or solvent during color change operations. Unfortunately, conventional pressure transducers of the type described cannot be readily flushed of coating material, since "dead end" spaces exist in the manifold to the sides of the inlet and outlet passages and flushing media tends to follow a straight line path of least resistance between the inlet and outlet. Consequently, unless flushing intervals are excessively long the entirety of the manifold surfaces are not cleaned and subsequently supplied paint is contaminated.

Object of the Invention

The primary object of the invention is to provide an improved structure for a manifold of a transducer for sensing pressure of fluid, which may readily be flushed of fluid of one type in preparation for receiving fluid of another.
Summary of the Invention

In accordance with the present invention, a manifold for accommodating a flow of fluid therethrough and configured for readily being flushed of the fluid by flushing media, comprises a housing having a chamber therein and an inlet to and an outlet from the chamber in proximity to and on opposite sides of the periphery thereof. At least one channel is formed in the housing in the chamber in communication with the inlet and extending toward peripheral side areas of the chamber, whereby flushing media introduced at the inlet flows through the chamber to the outlet, with at least one channel distributing the flushing media to all of the surfaces of the manifold for thoroughly cleaning the same of fluid.

Brief Description of the Drawings

Fig. 1 is a cross sectional side elevation view of a transducer for sensing the pressure of fluids, having a flushable manifold structured in accordance with the teachings of the invention;

Fig. 2 is a plan view taken substantially along the lines 2-2 of Fig. 1, and

Fig. 3 is taken substantially along the lines 3-3 of Fig. 2.

Detailed Description

Figs. 1 and 2 illustrate a pressure transducer, indicated generally at 20, having a flushable manifold configured in accordance with the invention. The transducer includes a lower housing 22 having on its upper surface a raised annular wall 24 defining therein a circular recess 26. An inlet 28 to the housing is connectable with a supply of fluid (not shown) such
as paint, and communicates with the recess adjacent its circumference. An outlet 30 from the housing is connectable with a point of delivery of the paint, for example with spray paint apparatus (not shown), and communicates with the recess adjacent its circumference at a point substantially opposite or about 180° from the inlet.

To enclose the recess 26 for a flow of paint therethrough from the inlet to the outlet, an annular seal 32 is around the outer circumference of the wall 24 and a diaphragm 34 of a flexible material is on the seal and closes the opening. An outer circular disc 36 of relatively rigid material and having a circular opening 38 is on the upper surface of the diaphragm, and an inner circular disc 40 of relatively rigid material is received within the opening 38. An upper housing 42 mounted on the upper surface of the lower housing receives the seal 32, diaphragm 34 and plates 36 and 40 within a circular recess 44 in a lower surface thereof. A plunger 46 is slidable within a bore 48 in the upper housing, a microswitch 50 having an actuating lever 52 is mounted on the upper housing and the plunger is of sufficient length to extend between and contact the actuating lever and the disc 40.

With the diaphragm 34 closing the top of the recess 26, a manifold is defined within the recess for a flow of fluid between the inlet 28 and the outlet 30. The microswitch actuating lever 52 is urged downwardly by any suitable means, such as by a spring (not shown), so that in the absence of fluid under pressure within the manifold the lever moves downwardly and forces the plunger 46, the disc 40 and the center portion of the diaphragm 34 downwardly. Under this condition, an output from the microswitch indicates fluid within the manifold which is at less than a selected pressure. However, upon fluid in the manifold having at least the selected pressure, the center
portion of the diaphragm is moved upwardly to move the actuating lever upwardly, so that the output from the microswitch then indicates a fluid within the manifold which is at least at the selected pressure.

When the transducer 20 is connected in line with a paint supply conduit for spray coating apparatus, the microswitch output indicates whether the paint supplied to the apparatus is at least at the selected pressure for proper coating of articles. However, it is often necessary to paint articles a wide variety of colors, and it may not be practical to establish separate spray coating stations or production lines for the purpose, or for that matter to spray a long sequence of articles one color, and then another long sequence a second color, etc. Instead, color change systems are used, and enable a plurality of supply containers of paint of different colors to be selectively connected with the supply line to provide to the spray coating apparatus paint of a selected color. However, upon changing from paint of one color to paint of another, to prevent contamination of the subsequently sprayed paint the spray paint system, including the pressure transducer, must first be cleansed of the previously supplied paint. For the purpose, the fluid inlet to the system is connected with a supply of flushing media which usually comprises alternate applications of solvent for the paint and compressed air, whereby flushing media flows through the system to cleanse the same.

To the extent described, the pressure transducer 20 is generally conventional and it is difficult to thoroughly and quickly clean the manifold during color changes. That is, flushing media introduced at the inlet 28 tends to follow a straight line path of least resistance between the inlet and outlet 30,
leaving side areas in the manifold which are not thoroughly cleaned. Consequently, absent an unreasonably long duration flow of flushing media portions of the diaphragm 34 and of the wall areas of the recess 26 remain contaminated, which can impair the color quality of the subsequently sprayed paint.

In overcoming the disadvantages of conventional pressure transducers, as shown in Figs. 2 and 3 at least one channel 54 is formed in the housing 22 within the recess 26 and extends between the inlet 28 and side areas of the recess and toward the outlet 30. For the embodiment shown, the channel is crescent shaped, extends within the recess adjacent to and along the circumference thereof, has an arcuate extent of about 180° and intersects the inlet at about its midpoint. The walls of the channel may have any suitable configuration, for example the V-shaped cross section shown, and the geometry of the channel causes flushing media introduced at the inlet 28 to readily flow within the channel to the side areas of the manifold and across the entirety of the face of the diaphragm and the wall areas of the recess as it flows from the inlet to the outlet. Consequently, during color change operations flushing media introduced at the inlet readily, rapidly and uniformly flows across and contacts all of the manifold surfaces to thoroughly and quickly clean the same of coating material, whereby the time required to clean the transducer is considerably shortened and there is no contamination of subsequently supplied coating material.
What is Claimed is:

1. A manifold for accommodating a flow of fluid therethrough and configured for readily being flushed of fluid by flushing media, comprising a housing having a chamber therein, a fluid inlet to and a fluid outlet from said chamber in proximity to opposite sides of the periphery of said chamber, and at least one channel formed in said housing in said chamber in communication with said inlet and extending to areas of said chamber to the sides of said inlet and outlet and toward said outlet, whereby flushing media introduced at said inlet flows within said at least one channel and through said chamber to said outlet, said at least one channel distributing the flushing media to all of the surfaces of the manifold for thoroughly cleaning the same of fluid.

2. A manifold as in claim 1, wherein said chamber is generally cylindrical and said at least one channel is a crescent shaped channel extending along and in proximity to the circumference of said chamber, having an arcuate extent less than said circumference and extending across said inlet but not said outlet.

3. A manifold as in claim 1, wherein said housing chamber comprises a recess in said housing, said inlet and outlet are in proximity to and on opposite sides of the periphery said recess, and at least one channel is formed in said housing in said recess in communication with said inlet and extending to areas of said recess to the sides of said inlet and outlet; and including a diaphragm of flexible material on said housing over and closing said recess, and means for sensing outward flexure of said diaphragm in response to occurrence of fluid under at least a selected pressure in said recess, whereby
fluid introduced at said inlet flows through said at least one channel and said recess to said outlet and said sensing means senses whether the fluid has at least said selected pressure, and whereby flushing media introduced at said inlet flows within said at least one channel and through said recess to said outlet, said at least one channel distributing the flushing media to all of the surfaces of said diaphragm and recess to quickly and thoroughly clean the same of fluid.

4. A pressure transducer as in claim 3, wherein said recess is cylindrical and said at least one channel is crescent shaped and extends along and in proximity to the circumference of said recess, has an arcuate extent less than said circumference and extends across said inlet but not said outlet.

5. A pressure transducer as in claim 1 or 3, wherein said inlet and outlet are at points approximately 180° apart in said chamber.

6. A pressure transducer as in claim 1 or 3, wherein said channel intersects said inlet at about the midpoint of the extent of said channel.

7. A manifold as in claim 1 or 3, wherein said channel has a generally V-shaped cross section.
