SYSTEM AND METHOD FOR GEOGRAPHICALLY LOCATING A CELLULAR DEVICE

5

TECHNICAL FIELD

This invention relates to systems and methods for geographically locating cellular devices; and in particular to the use of such systems and methods for locating vehicles in a traffic information system. The invention has application with all types of devices which communicate with wireless networks, for example, but not exclusively, GSM, GPRS, EDGE, CDMA and
10 Wide band CDMA based networks.

BACKGROUND

Determining the geographical location of a cellular device, such as a mobile phone, is useful in a variety of applications, including applications in the field of location-based services.
15 In traffic information systems, for example, the locations of vehicles may be determined based on the locations of drivers' cellular devices, in order to form an image of traffic conditions. The location of a cellular device or similar wireless device can be determined based on data acquired from the cellular network itself. In particular, the location of a device can be specified in terms of the network cell in which the cellular device is located, as defined by a cell-identifier,
20 possibly in addition to other data such as a time-advance.

Certain alternative techniques involve sampling data at a relatively low level in the network (closer to the base stations), such as the Abis-interface in GSM networks, for example, using power measurement reports of signal strength from mobile devices. The techniques based on interfaces at low levels in the network are troublesome and expensive to implement. Certain
25 alternative techniques applied in traffic monitoring rely on recording handover patterns by driving routes repetitively and storing the patterns in a database for use in subsequent route determinations based on pattern matching.

None of these alternative techniques offers a cost efficient and accurate technique for determining the geographical location of cellular devices. The present invention seeks to
30 provide improved techniques for determining the geographical location of cellular devices.

SUMMARY

According to an aspect of the present invention, there is provided a method for geographically locating a cellular device, the method comprising determining an effective cell-area for each of a first cell and a second cell in a cellular network, and

5 determining a handover area within which the cellular device is likely to be located when control of the cellular device is transferred from the first cell to the second cell,

wherein the determination of the handover area and the effective cell-area for each of the first cell and the second cell are made based on a topological relationship between the first cell and the second cell.

10 According to another aspect of the present invention there is provided a method for geographically locating a cellular device, the method comprising determining a handover area within which the cellular device is likely to be located when the cellular device is handed over from one or more first cells to a second cell. The determination of the handover area and
15 the effective cell-area for is preferably made based on a topological relationship between the plurality of cells involved. In CDMA based networks this determination may involve the plurality of cells in the active set.

According to an aspect of the present invention there is provided a method for geographically locating a cellular device, the method comprising determining an effective cell-
20 area for a plurality of cells in a cellular network and determining a handover area within which the cellular device is likely to be located. The determination of the handover area and the effective cell-area for each of the plurality of cells is based on a topological relationship between said plurality of cells.

According to an aspect of the present invention there is provided a method for
25 geographically locating a cellular device, the method comprising determining an effective cell-area for each of a first cell and a second cell in a cellular network and determining a handover area within which the cellular device is likely to be located when control of the cellular device is transferred from the first cell to the second cell. The determination of the handover area and the effective cell-area for each of the first cell and the second cell are made based on a topological
30 relationship between the first cell and the second cell.

According to another aspect of the present invention, there is provided a method for geographically locating a cellular device in a cellular network comprising a first antenna for a first cell and a second antenna for a second cell, the method comprising (i) determining an effective radius R_i for each of a set of i different topological relationships between the first cell and the second cell, (ii) determining an angle α for which, when the first antenna is contained within the second cell, and when an angle β formed by a line between the first antenna and the second antenna and a sector limit line of the second cell is less than the angle α , the second cell will be extended beyond the sector limit line, (iii) determining a first extension width E_1 of a first rectangular extension added to a sector limit line of the second cell when the angle β is less than the angle α , (iv) determining a second extension width E_2 of a second rectangular extension added to a sector limit line of the second cell when the first antenna is outside the second cell, and when an inner angle formed between a sector limit line of the second cell and a line between the first antenna and the second antenna, is greater than 180 degrees, (v) determining a first penumbra width W_1 of a first rectangular strip between a line of equal intensity of signal reception from the first antenna and the second antenna, and a first strip limit proximal to a cell into which the cellular device is moving, (vi) determining a second penumbra width W_2 of a second rectangular strip between the line of equal intensity and a second strip limit proximal to a cell out of which the cellular device is moving, and (vii) determining a handover area within which the cellular device is likely to be located when control of the cellular device is transferred from the first cell to the second cell, the determination of the handover area being based on at least a subset of the effective radii R_i , the angle α , the first extension width E_1 , the second extension width E_2 , the first penumbra width W_1 , and the second penumbra width W_2 .

According to another aspect of the present invention, there is provided a method of geographically locating a cellular device by determining the area in which handover involving a first cell or set of cells and a further cell occurs, the method comprising modeling at least a portion of a cell reception area of said first cell or set of cells and said further cell, and defining a handover area comprising overlapping portions of said first cell or set of cells and said further cell area(s).

According to another aspect of the present invention, there is provided a method of geographically locating a cellular device by determining the area in which handover from a first

cell to a second cell occurs, the method comprising modeling at least a portion of a cell reception area of said first cell and said second cell and defining a handover area comprising overlapping portions of said first and second cell areas.

According to another aspect of the present invention, there is provided a method
5 of monitoring traffic flow by determining successive locations of a plurality of cellular devices located in a plurality of vehicles, the method comprising repeat determination of the location of at least some of the plurality of cellular devices. This determination is preferably by means of sampling the locations of the at least some of the cellular devices to determine a present picture of traffic flow. The step of determining the location of a cellular device of the plurality
10 comprises determining the area in which handover from a first cell or set of cells to a further cell occurs, the handover determination being based on modeling at least a portion of a cell reception area of said first cell or set of cells and said second cell, and defining the handover area to comprise overlapping portions of said first and second cell areas.

According to another aspect of the present invention, there is provided a method of
15 monitoring traffic flow by determining successive locations of a plurality of cellular devices located in a plurality of vehicles, the method comprising repeat determination of the location of at least some of the plurality of cellular devices. This determination is preferably by means of sampling the locations of the at least some of the cellular devices to determine a present picture of traffic flow. The step of determining the location of a cellular device of the plurality
20 comprises determining the area in which handover from a first cell or set of cells to a further cell occurs, the handover determination being based on modeling at least a portion of a cell reception area of said first cell or set of cells, and said further cell and defining the handover area to comprise overlapping portions of said first and further cell areas.

According to another aspect of the present invention, there is provided a method of
25 monitoring traffic flow by determining successive locations of a plurality of cellular devices located in a plurality of vehicles, the method comprising repeat determination of the location of at least some of the plurality of cellular devices. This determination is preferably by means of sampling the locations of the at least some of the cellular devices to determine a present picture of traffic flow. The step of determining the location of a cellular device of the plurality
30 comprises determining the area in which handover from a first cell to a second cell occurs, the

handover determination being based on modeling at least a portion of a cell reception area of said first cell and said second cell and defining the handover area to comprise overlapping portions of said first and second cell areas.

According to another aspect of the present invention, there is provided apparatus for
5 geographically locating a cellular device, the apparatus comprising an effective cell-area module for determining an effective cell-area for each of a first cell and a second cell in a cellular network and a handover area module for determining a handover area within which the cellular device is likely to be located when control of the cellular device is transferred from the first cell to the second cell. The determination of the handover area and the effective cell-area for each of
10 the first cell and the second cell are made based on a topological relationship between the first cell and the second cell.

According to another aspect of the present invention, there is provided apparatus for geographically locating a cellular device by determining the area in which handover from a first cell to a second cell occurs, the apparatus comprising an effective cell-area module for modeling
15 at least a portion of a cell reception area of said first cell and said second cell, and a handover area module for defining a handover area comprising overlapping portions of said first and second cell areas

According to another aspect of the present invention, there is provided apparatus for monitoring traffic flow by determining successive locations of a plurality of cellular devices
20 located in a plurality of vehicles. The apparatus comprises (i) a handover area module for defining a handover area comprising overlapping portions of a modeled cell reception area of at least a portion of each of a first cell and a second cell of a cellular network, and (ii) a sampler module for sampling a set of repeated location determinations of at least some of the plurality of cellular devices, to determine a present picture of traffic flow, wherein each such location
25 determination is based at least in part on the handover area defined by the handover area module for a given cellular device moving between a given first cell and second cell of the cellular network.

According to a an aspect of the present invention, there is provided a method for
30 geographically locating a cellular device, the method comprising:

using an algorithm to determine a handover area within which a cellular device is likely to be located when a control function of the network performs a handover involving addition of a cell to an active set of cells,

wherein the determination of the handover area comprises modeling based on a
5 topological relationship between a plurality of cells in the active set.

According to a an aspect of the present invention, there is provided a method for geographically locating a cellular device, the method comprising:

using an algorithm to determine an area within which a cellular device is likely to be
10 located when a control function records an event which can be connected to concurrent control of more than one cell, wherein the determination of the area comprises modeling based on a topological relationship between a plurality of cells.

According to another aspect of the present invention there is provided an apparatus for
15 geographically locating a cellular device, the apparatus comprising:

an effective cell-area module for determining an effective cell-area for each of a plurality of cells in an active set of cells defined in relation to the mobile device;

a handover area module for determining a handover area within which the cellular device is likely to be located when a control function of the network performs a handover involving
20 addition of a cell to the active set of cells,

wherein the determination of the handover area and the effective cell-area for each of the plurality of cells is made based on a topological relationship between said plurality of cells.

According to another aspect of the present invention, there is provided a method of
25 geographically locating a cellular device by determining the area in which handover from a first cell or groups of cells to a further cell occurs, the method comprising:

modeling at least a portion of a cell reception area of said first cell or groups of cells and said further cell; and

defining a handover area comprising overlapping portions of said first cell or groups of
30 cells and said further cell.

According to another aspect of the present invention there is provided an apparatus for geographically locating a cellular device, the apparatus comprising:

an effective cell-area module for determining an effective cell-area for each of a plurality
5 of cells in an active set of cells defined in relation to the mobile device;

a handover area module for determining a handover area within which the cellular device is likely to be located when a control function of the network performs a handover involving addition of a cell to the active set of cells,

wherein the determination of the handover area and the effective cell-area for each of the
10 plurality of cells is made based on a topological relationship between said plurality of cells.

According to another aspect of the present invention, there is provided a method of monitoring traffic flow by determining successive locations of a plurality of cellular devices located in a plurality of vehicles, the method comprising:

15 repeatedly determining the location of at least some of the plurality of cellular devices;
and

sampling the locations of the at least some of the cellular devices to determine a picture of traffic flow;

wherein determining the location of a cellular device of the plurality comprises
20 determining the area in which handover occurs, the handover determination being based on:
modeling at least a portion of a cell reception area of a first cell or group of cells and a further cell; and

defining the handover area to comprise overlapping portions of said first cell area or groups of cell areas and said further cell area.

25

According to an aspect of the present invention, there is provided apparatus for geographically locating a cellular device by determining the area in which handover from a first cell or group of cell to a further cell occurs, the apparatus comprising:

an effective cell-area module for modeling at least a portion of a cell reception area of
30 said first cell or groups of cells and said further cell; and

a handover area module for defining a handover area comprising overlapping portions of the area of said first cell or group of cells and the further cell area.

According to another aspect of the present invention there is provided an apparatus for
5 monitoring traffic flow by determining successive locations of a plurality of cellular devices located in a plurality of vehicles, the apparatus comprising:

a handover area module for defining a handover area comprising overlapping portions of a modeled cell reception area of at least a portion of each of a first cell or group of cells and a further cell of a cellular network; and

10 a sampler module for sampling a set of repeated location determinations of at least some of the plurality of cellular devices, to determine a present picture of traffic flow, wherein each such location determination is based at least in part on the handover area defined by the handover area module for a given cellular device moving between a given first cell or group of cells a and further cell of the cellular network.

15 Thus, although techniques are known for determining the location of a cellular device based on the network cell in which the device is located, the accuracy of such techniques is limited by the large geographical area covered by each cell. Other techniques are known in which a specific machine is used to actively monitor the location of given handsets by request.
20 However, such techniques load the network, and are therefore costly and limited in capacity.

Additional advantages and novel features of the invention will be set forth in part in the description which follows, and in part will become apparent to those skilled in the art upon examination of the following and the accompanying drawings; or may be learned by practice of the invention.

25

BRIEF DESCRIPTION OF THE DRAWINGS

For a better understanding of the present invention, and to show how the same may be carried into effect, reference will now be made, by way of example only, to the accompanying
30 drawings, in which:

Fig. 1 shows first and second cells of a cellular network having antennas located at the same point, in accordance with an embodiment of the invention;

Fig. 2 shows first and second cells of a cellular network, the cells having antennas located at different points, and oriented to face each other, in accordance with an embodiment of the invention;

Fig. 3 shows first and second cells of a cellular network, the cells having antennas located at different points, and having sectors that do not overlap, in accordance with an embodiment of the invention;

Fig. 4 shows first and second cells of a cellular network, the cells having antennas located at different points, which face at an acute angle to each other, and whose sectors overlap, in accordance with an embodiment of the invention;

Fig. 5 shows an effective cell-area with extensions of a sector when one antenna is contained in the sector of another cell, near one of its limiting lines, in accordance with an embodiment of the invention;

Fig. 6A shows an effective cell-area with extensions of a sector when a second antenna is outside the limits of the sector of a first antenna, and when an inner-angle criterion is satisfied for two edges of the sector, in accordance with an embodiment of the invention;

Fig. 6B shows an effective cell-area with extensions of a sector when a second antenna is outside the limits of the sector of a first antenna, and when an inner-angle criterion is satisfied for one edge of the sector, in accordance with an embodiment of the invention;

Fig. 7 illustrates the determination of a penumbra area around the line of equal intensity between two antennas, in the case in which two cells have antennas located at the same point, in accordance with an embodiment of the invention;

Fig. 8 illustrates the determination of a penumbra area around the line of equal intensity between two antennas, in the case in which two cells have antennas located at different points, and are oriented to face each other, in accordance with an embodiment of the invention;

Fig. 9 illustrates the determination of a handover area for the case in which two cells have antennas located at different points, and are oriented to face each other, in accordance with an embodiment of the invention;

Fig. 10 illustrates the determination of a handover area for the case in which a line of equal intensity is not well-defined, in accordance with an embodiment of the invention;

Fig. 11 shows a ring-sector, which is used to model the estimated location of a cellular device when a cellular network uses time advance data, in accordance with an embodiment of the invention;

Fig. 12 is a block diagram of a traffic information system, as part of which an embodiment according to the invention may be used; and

DETAILED DESCRIPTION

Cellular networks operate using a network of antennas, each of which communicates messages to and from cellular devices located in a given area, called a cell. Cell areas from different antennas overlap, so that the domain of operation of the cellular network is completely covered. At any given time, a cellular device is under the control of a single cell of the network. The controlling cell is usually the one whose reception intensity is the strongest at the location of the cellular device. When a cellular device is in motion, it traverses from cell to cell, and its control is "handed over" from one cell to another.

Operation and management of cellular networks require monitoring many events that occur with respect to cellular devices. Such events are related for example to the calls it is making, like call initiation and call termination, and its mobility, like location update and handovers. We use in the following description certain GSM technology terminology, but wherever used we intend to refer also to the parallel terms in other network technologies.

The usage of all or some of those events, especially those events that are recorded at the "A-interface" (or the "parallel" in certain network technologies) provides a cost effective method to locate a cellular device. In the following we describe a way to do extract the location out of handover events, but this can be done for other events that are recorded and can be connected to concurrent control of more than one cell.

While the preferred embodiments disclosed herein are described with respect to a type of hard hand overs applying for example in GSM based networks, the principles and benefits of the invention also apply to soft handovers and combinations of hard and soft handovers. In this context, the most basic form of handover is that used in most 1G and 2G systems and may be regarded as where a device with a call in progress is redirected from one cell transmitter and receiver and frequency pair to another cell transmitter and receiver using a different frequency pair without interrupting the call. If the terminal can only be connected to one base station and therefore needs to drop the connection when it is connected to the other this is regarded as a hard handover.

A skilled person will appreciate that in CDMA, including WCDMA- based systems, the user can be connected to several base stations simultaneously, combining the data from all transmitters in range into one signal using a RAKE receiver. The set of base stations the terminal is connected to contemporaneously is referred to as the "active set". A "soft handover" happens when there are several base stations in the active set and the terminal drops one of these to add a new one or adds a new one without dropping an existing base station from the active set. In W-CDMA there is a special case called "softer handover" where several connections in the active set point to the same base station. A softer handover happens when one of these connections is dropped for another from the same base station. There are also inter-system handovers where a connection is transferred from one access technology to another, e.g. a call being transferred from GSM to W-CDMA. The principles and advantages of the present invention apply in respect of all of the aforementioned types of handover, and the terms of the claim should be construed accordingly, although the precise implementation and / or actual benefit in each case may vary in minor ways which will be appreciated by a skilled person.

Accordingly, at any given time, a cellular device is under control of one (in GSM networks) or more cells of the network. The controlling cell or cells are the ones whose reception is deemed suitable for purpose and the event of giving control to (or adding) a new cell is referred to herein as "handover". The handover event points therefore to a momentary situation (the exact time of which is included in the event record) where the cellular phone is under control of two or more cells, that is in an approximately equal reception intensity of the said cells. This means, that by drawing the area where all said cells have approximately equal

reception, it can be estimated with high probability that the cellular phone is located within this area.

For clarity, the following exemplary embodiment refers to a case of control transfer between two cells, as relevant to GSM networks, but the same method can be implied to cases
5 where more than two cells are involved, for example it may be applied to an active set of cells in a CDMA-based network, by applying the principles and method steps described below to all those cells.

Often, a handover event in GSM networks and the like involving cell A and cell B occurs when a cellular device moves from an area where the intensity of the signal from the cell A
10 antenna is higher than that of the cell B antenna, to an area where the intensity of the signal from the cell B antenna is higher than that of the cell A antenna. Thus, the handover event theoretically occurs when the cellular device crosses a line of equal-intensity signals from both cells. However, in reality, the handover does not occur exactly on the equal-intensity line, but rather within a certain penumbra area around the equal-intensity line. The form and dimension
15 of the penumbra area depends on various parameters, including the relative positioning of the cells involved, which is determined by the location and orientation of the antennas.

In an embodiment according to the invention, there is disclosed a technique for geographically locating a cellular device with high confidence at the moment that handover occurs, by determining the "handover area," which is the area in which handover from cell A to
20 cell B might occur at high probability. Because the handover areas are found to be smaller than cell areas, on average, this technique offers better accuracy than techniques that use only the cell area to locate a device. Additionally, handover events are recorded by the cellular network management system, and are therefore available at no additional cost, so that the technique is relatively inexpensive.

25 In order to implement a preferred embodiment, a polygon is be constructed to represent the handover area. In order to do so, four simplifying assumptions are made.

First, the simplifying assumption is made that the control area of an antenna (a cell area) is a sector, generally of 120 degrees, whose center is the antenna; see, for example, sector 101, centered around antenna 100 of the embodiment of Fig. 1.

Second, the simplifying assumption made is that the reception intensity of signals from the antenna grows in inverse relation to the distance from the antenna, while the cellular device is located within the sector. Other factors that influence the reception intensity of signals from the antenna are ignored, such as the exact azimuth of the antenna, the effect of reflections, and
5 the effect of multi-pathing; because the influence of such factors is limited, and the factors often statistically offset one another.

The third simplifying assumption made is that the reception intensity from the antenna outside the sector is significantly lower than the reception intensity within the sector.

The fourth simplifying assumption made is that the handover from one cell to another
10 occurs within a reasonable distance from a point where the cellular device receives a signal from both antennas at equal intensity.

Based on these assumptions, an embodiment according to the invention initially models a cell's reception area as a sector with a finite radius. Beyond that radius, reception does occur, but it is significantly weaker than reception within the radius. Also, there are regions of weak
15 reception beyond the limiting lines of the sector; and in the area behind the antenna, in the opposite direction from the sector. In some cases, control over a cellular device can be handed over within these weak reception areas. An embodiment according to the invention therefore extends the cell reception area, initially modeled as a sector, into these weak reception areas, in certain circumstances. Once the effect of such circumstances has been considered, and the cell
20 sector area possibly extended (or not), the resulting model of the cell's reception is here termed the effective cell area. As will be seen further below, whether to extend a cell sector area can be determined based on the relative positions and orientations of the two antennas between which a device is moving. For example, extensions can be made when one cell's antenna is situated within the other cell's sector, but very close to the sector's limit (as in the embodiment of Fig. 5);
25 or when one cell's antenna is situated outside the other cell's sector in specific configurations (as in the embodiment of Fig. 6). In these cases, the effective cell area includes extensions beyond the sector limits. Also, the radius of the sector can be extended or diminished, in some cases, based on the distance between the antennas of the two cells; the resulting radius is here termed the effective radius of the cell.

By taking such effects into consideration, an embodiment according to the invention constructs a polygon representing the handover area out of a combination of two areas: 1) the overlap part of the effective cell-areas of the two cells between which the cellular device is moving; and 2) the penumbra area around the equal-intensity line between the antennas of the two cells. As will be seen below, the relative positioning of the two cells plays a significant role in the determination of these two areas; and there are cases in which the penumbra area is impossible to define, and therefore only the effective cell area is used.

Figs. 1 through 4 illustrate four possible topological relative positions of two cells, in accordance with an embodiment of the invention. In Fig. 1, a first cell 101 and a second cell 102 have antennas located at the same point 100. In Fig. 2, a first cell 201 produced by a first antenna 203 is oriented to face a second cell 202, produced by a second antenna 204; the two cells have antennas located at different points, and are facing each other. In Fig. 3, a first cell 301 and a second cell 302 have antennas 303 and 304 located at different points, and their sectors do not overlap. Fig. 4 shows an example which does not fit into the topological categories of Figs. 1 through 3, thereby representing all other topological cases; in this case, antennas 403 and 404 are located at different sites, are facing at an acute angle to each other, and the sectors 401 and 402 overlap.

In an embodiment according to the invention, a method for geographically locating a cellular device includes three steps: first, determining the effective cell-area of each cell; second, determining the penumbra area around the equal-intensity line; and third, combining the areas determined in the first and second steps to determine the handover area.

A first step of an embodiment according to the invention comprises determining the effective cell-area of each cell. In order to do so, there is first determined an effective radius of the cell-sector. The existence of such a radius is premised on the second simplifying assumption above, i.e. that the reception intensity of the antenna within the sector grows in inverse relation to the distance from the antenna. Determining the effective radius depends on the topological case involved: in the topology of the embodiment of Fig. 1, in which the antennas are located at the same site 100, the effective radius is R_1 . In all other topological cases, shown in the embodiments of Figs. 2 through 4, the effective radius is equal to $R_i \cdot D$, where D is the distance between the antennas, and R_i is a constant factor, different for each topological case (i.e. for

Figs. 2 through 4, the index $i = 2, 3$, and 4). In accordance with an embodiment of the invention, other methods for determining an effective radius may be used; including other methods that relate an increased distance between the antennas to an increased effective radius.

Next, after determining the effective radius of the cell-sector, the effective cell-area is
 5 determined by extending the cell sector beyond the edges of the sector, in certain cases. This determines the sidelines of the effective cell-area. The extension of the cell-area beyond the edges of the sector is required in for example two cases: 1) when one antenna is contained in the sector of the other cell, very near one of its limiting lines, as will be illustrated with reference to the embodiment of Fig. 5; and 2) when one antenna is outside the sector of the other cell, and the
 10 inner angle between the limiting line and the line connecting both antennas is greater than 180 degrees, as will be illustrated with reference to the embodiments of Figs. 6A and 6B.

In the first extension case, shown in the embodiment of Fig. 5, the angle β , 503 that is formed by the line 505 between the two antennas 501 and 502, and one of the limiting lines 506 of the first sector, is less than a pre-determined angle α , 504. The predetermined angle α is pre-
 15 determined as the angle within which an antenna 502 is sufficiently close to the limiting line 506 to warrant an extension of the cell-area beyond the edges of the sector. When the angle β is less than α , the sector is extended only to one side, i.e. the side 506 that is near to the second antenna 502. A relatively small rectangular extension 508, which has a width dimension E_1 , 507, is added to the side 506 of the sector.

20 In the second extension case, described first with reference to the embodiment of Fig. 6A, a second antenna 602 is outside the limits of the sector 603 of a first antenna 601. In such a case, it is determined whether the inner angle, i.e. the angle that contains the first sector 603 itself, and that is formed between an edge 607 or 608 of the sector 603 and the line 609 between the two antennas 601 and 602, is greater than 180 degrees. If so, an extension is made to the sector edge
 25 607 or 608 for which that condition is satisfied. For example, consider edge 607 of the sector 603. The inner angle between edge 607 and the line 609 is angle 605; and that angle 605 is greater than 180 degrees. Accordingly, edge 607 is extended by a rectangular extension 610. Similarly, considering edge 608 of the sector 603, the inner angle between edge 608 and the line 609 is angle 606; and that angle 606 is greater than 180 degrees. Accordingly, edge 608 is
 30 extended by a rectangular extension 611. In the second extension case of Figs. 6A and 6B, the

rectangular extensions, such as extensions 610 and 611, have a relatively larger width E_2 , 613 than the width E_1 , 507 of the rectangular extension of Fig. 5. Also, when there are two rectangular extensions to a given sector, as with extensions 610 and 611 on sector 603, an additional triangular extension 612 is made at the back of antenna 601 by connecting the two far
 5 corners 623 and 624 of the rectangular extensions; and the two extensions are of the same width E_2 . It should be noted that, whereas large extensions are made to sector 603 because antenna 602 is outside the limits of the sector of antenna 601 (and the inner-angle criterion is satisfied), the reverse is not necessarily the case for the other sector. That is, in this case, sector 604 will not be extended by an extension of the second type, because antenna 601 is within sector 604.

10 The embodiment of Fig. 6B shows another example of an extension of the second type, in which only one edge of a sector is extended with a large extension, instead of two. In particular, antenna 615 is outside the sector 616 of antenna 614. However, the inner angle 622 between sector edge 617 and the line 620 is exactly equal to 180 degrees (and therefore is not greater than 180 degrees), so that no extension is made to edge 617. By contrast, the inner angle 621
 15 between sector edge 618 and the line 620 is greater than 180 degrees; therefore, an extension 619 of the second type is made to edge 618.

Having determined the effective cell-area (in this embodiment by determining an effective radius and, in some cases, extending the edges of the sector), the second step is to determine the penumbra area around the line of equal intensity between the two antennas, as
 20 illustrated with reference to the embodiments of Figs. 7 and 8. In this example, the penumbra area around the line of equal intensity is modeled as an asymmetrical rectangular strip around the line of equal intensity. The width W_1 of the rectangular strip between the line of equal intensity and the strip limit on the side of the cell into which the cellular device is moving, is longer than the width W_2 on the side of the cell out of which the cellular device is moving. For example,
 25 with reference to the embodiment of Fig. 7, the penumbra area around the line of equal intensity 710 is formed by two rectangular strips 706 and 707, for which the width W_1 , 708 of the strip 706 on the side of the sector 704 into which the cellular device is moving, is longer than the width W_2 , 709 of the strip 707 on the side of the sector 705 out of which the cellular device is moving. Each strip is formed between the line of equal intensity 710 and a strip limit 711 and
 30 712. Similarly, with reference to the embodiment of Fig. 8, the penumbra area around the line of

equal intensity 808 is formed by two rectangular strips 806 and 807, for which the width W_1 , 809 of the strip 806 on the side of the sector 805 into which the cellular device is moving, is longer than the width W_2 , 810 on the side of the sector 804 out of which the cellular device is moving.

In determining the penumbra area around the equal intensity line, according to an
5 embodiment of the invention, it is first necessary to determine the location of the equal intensity line, which varies depending on the topological case. In the first topological case of the embodiment of Fig. 1, which is also the case in Fig. 7, the equal intensity line is the bisector 710 of the cells' azimuths 702 and 703 (which emanate from the location 701 of the antennas). In the second and third topological cases of the embodiments of Figs. 2 and 3, the equal intensity line is
10 approximately the central perpendicular to the line connecting the two antennas. For example, in Fig. 8, which corresponds to the topological case of Fig. 2, the equal intensity line is the central-perpendicular 808 to the line 803 connecting the two antennas 801 and 802. In the fourth topological case of the embodiment of Fig. 4, the equal intensity points are difficult to define, and a strip similar to those of Figs. 7 and 8 does not exist.

15 Having determined the effective cell-area and the penumbra area around the line of equal intensity, a third step of this embodiment is to determine the handover area. For each of the topological cases except that of the embodiment of Fig. 4, the area in which each cell is potentially able to perform a handover is formed, for each cell, by the intersection of its effective cell-area and the penumbra area around the line of equal intensity. The cell A to cell B handover
20 area, as it is in this case, is then found as the union of the areas in which the two cells are potentially able to perform a handover. For example, with reference to the embodiment of Fig. 9, the handover area for a cellular device traveling from cell A, 901 to cell B, 902 is determined by first intersecting the effective area of cell A with the rectangular strip 903 of the penumbra area around the equal intensity line 904; then intersecting the effective area of cell B with the
25 rectangular strip 903; and then forming union of these two areas, which is represented as the shaded area 905. The embodiment of Fig. 9 illustrates the determination of the cell A to cell B handover area for the topological case of the embodiment of Fig. 2, in which the rectangular strip 903 is well defined. In the topological case of the embodiment of Fig. 4, for which a similar rectangular strip is not defined, the cell A to cell B handover area is found as the intersection of
30 the two effective cell-areas, each of which may include extensions of either the first or second

type described above. For example, in the embodiment of Fig. 10, the effective cell-area of sector 1001 has been extended by an extension 1002 of the first type, and the effective cell-area of sector 1003 has been extended by extensions 1004, 1005, and 1006 of the second type.

Because this is a topological case similar to that of the embodiment of Fig. 4, the handover area from cell 1001 to cell 1003 is equal to the intersection between their two effective cell-areas, which is shown as shaded area 1007. It should be noted that the only difference between a cell A to cell B handover area, and a cell B to cell A handover area, derives from the asymmetry of the penumbra area around the equal intensity line, which occurs in the topological cases of the embodiments of Figs. 1 through 3.

As can be seen from the embodiment of Fig. 10, the handover area 1007 determined in accordance with an embodiment of the invention herein, is much smaller than the effective areas of the cell sectors 1001 and 1003. Thus, on average, a method according to an embodiment of the invention, which determines the handover area, is more accurate in locating a cellular device than prior art techniques that rely on locating only the cell sector.

An embodiment according to the invention also improves accuracy, on average, when the cellular network specifies the location of a cellular device using time advance data, in addition to cell identifier data. Fig. 11 shows a ring-sector 1101, which is used to model the estimated location of a cellular device in such a case, in accordance with an embodiment of the invention. The additional time advance data restricts the location of the handset to a ring sector 1101 between two given radii 1102 and 1103 from an antenna 1104. It will be appreciated that use of time-advance data, or other possible data-specified by a cellular network, which may narrow the modeled cell area, can be used consistently with embodiments herein – for example by modifying the model for determining effective cell area. Thus, for example, in the embodiment of Fig. 11, the cell area may be modeled as a ring sector, which is possibly extended to create an effective cell area in a similar fashion to the techniques described herein. Other shapes for cell areas may also be used in accordance with an embodiment of the invention. Regardless of the shape of the effective cell area, techniques in accordance with an embodiment of the invention, on average, improve the accuracy of locating a cellular device. Using the ring sector of Fig. 11, for example, a similar rate of reduction in area may be obtained as when full sectors are used as above.

Those of skill in the art will appreciate that the generalized parameters mentioned above (such as parameters R_1 , R_2 , R_3 , R_4 , α , E_1 , E_2 , W_1 , and W_2), may be determined empirically and calibrated by field trials. For example, tests may be performed in which actual locations of test cellular devices are known, so that the actual locations can be empirically matched against the cell map to determine proper values for the parameters. The parameters may be estimated statistically based on the empirical results, and may be improved as test results and other data are accumulated over time. Other parameter may be used. Further, a selection from the aforementioned parameter or completely different parameters may be used. Where cellular systems other than GSM are used, e.g. CDMA-based cellular systems, embodiments may be modified for example such that the hand over area is modeled as a different shape or set of shapes arising from the arrangement of cells in the active set.

In accordance with an embodiment of the invention, a system and method for location of cellular devices may be used as part of a traffic information system, such as that described in U.S. Pat. No. 6,587,781 of Feldman et al., a summary block diagram of which is shown in the embodiment of Fig. 12. In this system, there is determined the location of each of a plurality of mobile sensors in vehicles traveling on a road network 12, which has been analyzed to form an oriented road section network 14. Other sources of traffic information may or may not be used to complement the mobile sensing. Position data 62 is collected over time from the mobile sensors, and sampled periodically by a sampler 1 for passage to a normalized travel time calculator 2. Based on the sampled data, the travel time calculator 2 determines a mean normalized travel time value for each oriented road section of the network 14. A fusion and current picture generator 3 then uses the calculated normalized travel times, as well as data obtained from other sensors, to generate a current picture of traffic conditions on the road network. A predictor 4 can then use the current picture, as well as rules from a patterns and rules generator 6, to predict traffic conditions or provide other information to a service engine 5, which may serve a variety of applications 7. The fusion and current picture generator 3 may fuse data from a variety of sources, including the normalized travel time calculator 2, traffic data from fixed sensors 60, traffic data from traffic reports 64, and traffic data from other sources 66.

In accordance with an embodiment of the invention, an apparatus for implementing the technique of locating cellular devices, described herein, can be used to generate traffic data using

cellular device locations from devices in vehicles. For example, when a handover area is determined for given cellular device, a traffic system can use the geographical area corresponding to the handover area that has been determined, as an estimate of the location of a vehicle in which that cellular device was located at the time that handover event occurred.

5 Based on the resulting position and time data for a large number of such vehicles, and traffic data from other sources, a normalized travel time calculator 2, or other traffic system component, can generate a picture of traffic conditions for a variety of uses, including for predicting upcoming traffic conditions. In one embodiment, a technique in accordance with those described herein for geographically locating a cellular device is implemented by the sampler module 1 of the
10 embodiment of Fig. 12. The sampler module 1 is fed position data 62, which may include streaming data relating to cellular handover events, from a cellular network. The position data 62 may include, for example, cell identifier and time advance data from a cellular carrier; as well as vehicle position data from a variety of other mobile sensor sources, such as GPS data or other Floating Vehicle Data. Vehicle position data 62 from each different type of mobile sensor
15 source is sampled by its own adjusted sampler sub-module (included in sampler module 1 of Fig. 12). Multiple sampler sub-modules may also be used for processing different types of data from the same mobile sensor source. For example, separate sampler sub-modules may be used for processing cellular handover data and cellular location server data.

Fig. 13 is a block diagram of an apparatus for locating cellular devices, in accordance
20 with an embodiment of the invention. This may be used, for example, in the traffic information system of the embodiment of Fig. 12. As summarized in the block diagram of the embodiment of Fig. 13, such an apparatus 1305 for locating cellular devices may include an effective cell-area module 1301 for determining cell-areas; a penumbra area module 1302 for determining the penumbra area around the line of equal intensity; and a handover area module 1303 for
25 determining the handover area. The apparatus 1305 for locating cellular devices may be implemented in a variety of different forms of hardware, as will be apparent to those of skill in the art upon reading the techniques disclosed herein. For example, the apparatus 1305 may comprise a computer processor or specialized signal processing circuit, which receives data 1300 on cellular handover events, or other cellular data, generated by a cellular network; and which
30 transmits a resulting calculated handover area to a location-based application 1304; for example,

the traffic information system of the embodiment of Fig. 12. Various method steps described in embodiments herein may be implemented as routines in computer program code running on a computer processor 1305, or as equivalent specialized circuits for data processing.

Also, an apparatus according to an embodiment of the invention need not be implemented in the form of the embodiment of Fig. 13. For example, two possible ways of implementing techniques herein are as follows (these examples are not intended to be limiting). In a first example, a cell-map of a cellular carrier may be available to a system according to the invention. In this case, handover areas for all possible combinations of neighboring cells can be determined, based on the cellular map, in an off-line process, and stored in a database accessible by a system according to the invention. When cellular data streams into the system, the system uses the cell identifiers and/or time advance data; or other cellular network data for a given handover event to consult the database (for example, using a lookup table) and thereby obtain the relevant handover area. Thus, in the first example, the functions of apparatus 1305 are performed off-line, and data 1300 is subsequently processed online with reference to the handover data created offline by module 1303. By contrast, in a second example, a cell-map is not available to a system according to the invention. Instead, the system receives the geographical parameters of the cells involved in each handover event, and calculates the handover areas online based on the data stream, using, for example, the embodiment of Fig. 13. The modules 1301-1303 of the embodiment of Fig. 13 need not be mapped directly onto different software modules; instead, the software may have a different or more complex architecture implementing equivalent functionality, as will be appreciated by those of skill in the art.

It will be appreciated that the embodiments admit of a wide range of modifications without departing from the inventive concepts. For example a skilled person will readily appreciate how the principles and benefits of the invention apply with various current and future frequency division multiple access (*FDMA*) and/or code division multiple access (*CDMA*) networks, or other networks using time division multiple access (*TDMA*) in combination with *FDMA* and *CDMA* principles. Another, less frequently mentioned alternative is polarisation division multiple access (*PDMA*).

A skilled reader will also appreciate that, while the foregoing has described what is considered to be the best mode and where appropriate other modes of performing the invention, the invention should not be limited to specific apparatus configurations or method steps disclosed in this description of the preferred embodiment. For example, while various

5 embodiments herein refer to geographically locating a “cellular device,” it will be appreciated that this term should be construed broadly to refer not only to mobile cellular phones or other handsets, but also, for example, to other modules in communication with a cellular network, such as vehicle-bound probes, laptops and specialist computer units which communicate with a cellular network. Those skilled in the art will also recognize that the invention has a broad range

10 of applications, particularly location base applications and services. For example, embodiments according to the invention for geographically locating a cellular device may be used in a wide variety of applications; including (but not limited to): location-based services, generally; traffic information systems; for emergency purposes, such as in locating a cellular device that was used to call an emergency number; for escape planning; and for security, intelligence, and national

15 defense applications.

What is claimed is:

1. A method for geographically locating a cellular device, the method comprising:

determining an effective cell-area for each of a first cell and a second cell in a cellular network; and

5 determining a handover area within which the cellular device is likely to be located when control of the cellular device is transferred from the first cell to the second cell;

wherein the determination of the handover area and the effective cell-area for each of the first cell and the second cell are made based on a topological relationship between the first cell and the second cell.

10

2. A method according to claim 1, further comprising:

determining a penumbra area around a line of equal intensity of reception between the first cell and the second cell.

15 3. A method according to claim 1, wherein the cellular network comprises a first antenna for the first cell and a second antenna for the second cell, and wherein the topological relationship is determined from amongst a set of topological cases comprising:

a first topological case in which the first antenna and the second antenna are located at a common location;

20 a second topological case in which the first antenna and the second antenna are located at different locations; and in which the first cell and the second cell are oriented to face each other;

a third topological case in which the first antenna and the second antenna are located at different locations, and in which the first cell and the second cell do not overlap; and

25 a fourth topological case in which none of the first, second, and third topological cases are satisfied.

4. A method according to claim 3, further comprising, when the topological relationship is determined to be one of the first, second, or third topological cases, determining a penumbra area around a line of equal intensity of reception between the first cell and the second cell.

30

5. A method according to claim 2 or 4, further comprising:

determining a first cell potential handover area by intersecting the effective cell-area of the first cell with the penumbra area;

5 determining a second cell potential handover area by intersecting the effective cell-area of the second cell with the penumbra area; and

determining the handover area for transfer of control of the cellular device by forming the union of the first cell potential handover area and the second cell potential handover area.

6. A method according to claim 1, further comprising:

10 determining the handover area for transfer of control of the cellular device by intersecting the effective cell-area of the first cell with the effective cell-area of the second cell.

7. A method according to claim 3, further comprising, when the topological relationship is determined to be the fourth topological case, determining the handover area for transfer of control of the cellular device by intersecting the effective cell-area of the first cell with the effective cell-area of the second cell.

8. A method according to claim 1, wherein determining the effective cell-area comprises using cell identifier data.

20 9. A method according to claim 1, wherein determining the effective cell-area comprises using time advance data.

10. A method according to claim 1, wherein determining the effective cell-area comprises 25 determining an effective radius of the first cell and the second cell.

11. A method according to claim 10, wherein, when a first antenna for the first cell and a second antenna for the second cell are located at a common location, the effective radius is determined as a radius of a sector-shaped cell.

30

12. A method according to claim 10, wherein, when a first antenna for the first cell and a second antenna for the second cell are not located at a common location, the effective radius is determined as the product of a distance between the first antenna and the second antenna and a constant factor based on the topological relationship between the first cell and the second cell.

5

13. A method according to claim 10, wherein determining the effective cell-area further comprises extending an edge of a sector-shaped cell.

14. A method according to claim 13, wherein extending the edge of the sector-shaped cell comprises, when a first antenna for the first cell is contained within the second cell, and when an angle β formed by a line between the first antenna and a second antenna for the second cell and a sector limit line of the second cell, is less than a predetermined angle α ,
extending the second cell beyond the sector limit line.

15. A method according to claim 14, wherein the second cell is extended by a rectangular extension beyond the sector limit line.

16. A method according to claim 13, wherein extending the edge of the sector shaped cell comprises, when a first antenna, for the first cell, is outside the second cell, and when an inner angle formed between a sector limit line of the second cell and a line between the first antenna and a second antenna for the second cell, is greater than 180-degrees,
extending the second cell beyond the sector limit line.

17. A method according to claim 16, wherein the second cell is extended by a rectangular extension beyond the sector limit line.

18. A method according to claim 16, wherein the second cell is extended beyond two sector limit lines.

19. A method according to claim 18, wherein the second cell is extended by two rectangular extensions, and wherein the method further comprises extending the second cell by a triangular extension connecting the two rectangular extensions.

5 20. A method according to claim 2 or 4, wherein determining the penumbra area comprises:
determining the location of the line of equal intensity; and
determining a rectangular strip around the line of equal intensity.

10 21. A method according to claim 20, wherein determining the location of the line of equal intensity comprises, when a first antenna for the first cell and a second antenna for the second cell are located at a common location, determining the line of equal intensity as the bisector of an angle formed by a first azimuth for the first cell and a second azimuth for the second cell.

15 22. A method according to claim 20, wherein determining the line of equal intensity comprises forming a central perpendicular to a line connecting a first antenna for the first cell and a second antenna for the second cell.

23. A method according to claim 20, wherein the rectangular strip is of asymmetrical width about the line of equal intensity.

20 24. A method according to claim 23, wherein a width W_1 of a first rectangular strip between the line of equal intensity and a first strip limit proximal to a cell into which the cellular device is moving, is longer than a width W_2 of a second rectangular strip between the line of equal intensity and a second strip limit proximal to a cell out of which the cellular device is moving.

25 25. A method according to claim 1, further comprising:
generating vehicle traffic data based at least in part on the handover area.

26. A method according to claim 25, further comprising:
30 sampling data received from the cellular network to determine the handover area.

27. A method according to claim 26, further comprising:

sampling vehicle position data from a plurality of different mobile sensor sources to generate the vehicle traffic data.

5

28. A method according to claim 25, further comprising:

storing a pre-determined handover area for the first cell and the second cell in a database; and

consulting the database to determine the handover area when data is received from the cellular network relating to a handover between the first cell and the second cell.

10

29. A method according to claim 25, further comprising:

determining the handover area using an online sampler which responds to streaming data received from the cellular network.

15

30. A method according to claim 1, wherein the first and second cells comprise part of a cellular network operating principles on one or more of: Frequency Division Multiple Access (FDMA), Time Division Multiple Access (TDMA), Polarisation Division Multiple Access (PDMA), and Code Division Multiple Access (CDMA).

20

31. A method according to claim 1, further comprising consideration of a third cell, the first second and third cells comprising part of a CDMA or WCDMA cellular network.

32. A method according to claim 31, further comprising consideration of a fourth cell, the first second, third and fourth cells comprising part of a CDMA or WCDMA cellular network.

25

33. A method for geographically locating a cellular device in a cellular network comprising a first antenna for a first cell and a second antenna for a second cell, the method comprising:

determining an effective radius R_i for each of a set of i different topological relationships between the first cell and the second cell;

30

determining an angle α for which, when the first antenna is contained within the second cell, and when an angle β formed by a line between the first antenna and the second antenna and a sector limit line of the second cell is less than the angle α , the second cell will be extended beyond the sector limit line;

5 determining a first extension width E_1 of a first rectangular extension added to a sector limit line of the second cell when the angle β is less than the angle α ;

determining a second extension width E_2 of a second rectangular extension added to a sector limit line of the second cell when the first antenna is outside the second cell, and when an inner angle formed between a sector limit line of the second cell and a line between the first
10 antenna and the second antenna, is greater than 180 degrees;

determining a first penumbra width W_1 of a first rectangular strip between a line of equal intensity of signal reception from the first antenna and the second antenna, and a first strip limit proximal to a cell into which the cellular device is moving;

determining a second penumbra width W_2 of a second rectangular strip between the line
15 of equal intensity and a second strip limit proximal to a cell out of which the cellular device is moving; and

determining a handover area within which the cellular device is likely to be located when control of the cellular device is transferred from the first cell to the second cell, the determination of the handover area being based on at least a subset of the effective radii R_i , the
20 angle α , the first extension width E_1 , the second extension width E_2 , the first penumbra width W_1 , and the second penumbra width W_2 ;

34. An apparatus for geographically locating a cellular device, the apparatus comprising:

an effective cell-area module for determining an effective cell-area for each of a first cell
25 and a second cell in a cellular network; and

a handover area module for determining a handover area within which the cellular device is likely to be located when control of the cellular device is transferred from the first cell to the second cell;

wherein the determination of the handover area and the effective cell-area for each of the first cell and the second cell are made based on a topological relationship between the first cell and the second cell.

5 35. An apparatus according to claim 34, further comprising:

a penumbra area module for determining a penumbra area around a line of equal intensity of reception between the first cell and the second cell.

10 36. An apparatus according to claim 34, wherein the cellular network comprises a first antenna for the first cell and a second antenna for the second cell, and wherein the topological relationship is determined from amongst a set of topological cases comprising:

a first topological case in which the first antenna and the second antenna are located at a common location;

15 a second topological case in which the first antenna and the second antenna are located at different locations, and in which the first cell and the second cell are oriented to face each other;

a third topological case in which the first antenna and the second antenna are located at different locations, and in which the first cell and the second cell do not overlap; and

a fourth topological case in which none of the first, second, and third topological cases are satisfied.

20

37. An apparatus according to claim 36, wherein the penumbra area module comprises means for, when the topological relationship is determined to be one of the first, second, or third topological cases, determining a penumbra area around a line of equal intensity of reception between the first cell and the second cell.

25

38. An apparatus according to claim 35 or 37, wherein the handover area module comprises means for:

determining a first cell potential handover area by intersecting the effective cell-area of the first cell with the penumbra area;

determining a second cell potential handover area by intersecting the effective cell-area of the second cell with the penumbra area; and

determining the handover area for transfer of control of the cellular device by forming the union of the first cell potential handover area and the second cell potential handover area.

5

39. An apparatus according to claim 34, wherein the handover area module comprises means for determining the handover area for transfer of control of the cellular device by intersecting the effective cell-area of the first cell with the effective cell-area of the second cell.

10 40. An apparatus according to claim 36, wherein the handover area module comprises means for, when the topological relationship is determined to be the fourth topological case, determining the handover area for transfer of control of the cellular device by intersecting the effective cell-area of the first cell with the effective cell-area of the second cell.

15 41. An apparatus according to claim 34, wherein the effective cell-area module comprises means for using cell identifier data.

42. An apparatus according to claim 34, wherein the effective cell-area module comprises means for using time advance data.

20

43. An apparatus according to claim 34, wherein the effective cell-area module comprises means for determining an effective radius of the first cell and the second cell.

25 44. An apparatus according to claim 43, wherein the effective cell-area module comprises means for, when a first antenna for the first cell and a second antenna for the second cell are located at a common location, determining the effective radius as a radius of a sector-shaped cell.

30 45. An apparatus according to claim 43, wherein the effective cell-area module comprises means for, when a first antenna for the first cell and a second antenna for the second cell are not

located at a common location, determining the effective radius as the product of a distance between the first antenna and the second antenna and a constant factor based on the topological relationship between the first cell and the second cell.

5 46. An apparatus according to claim 43, wherein the effective cell-area module comprises means for determining an extension of an edge of a sector-shaped cell.

47. An apparatus according to claim 46, wherein the effective cell-area module comprises means for determining an extension of an edge of a sector-shaped cell by :

10 determining whether a first antenna for the first cell is contained within the second cell, and whether an angle β formed by a line between the first antenna and a second antenna for the second cell and a sector limit line of the second cell, is less than a predetermined angle α ; and, if so,

extending the second cell beyond the sector limit line.

15

48. An apparatus according to claim 47, wherein the effective cell-area module comprises means for extending the second cell by a rectangular extension beyond the sector limit line.

20 49. An apparatus according to claim 46, wherein the effective cell-area module comprises means for determining an extension of an edge of a sector-shaped cell by:

determining whether a first antenna, for the first cell, is outside the second cell, and whether an inner angle formed between a sector limit line of the second cell and a line between the first antenna and a second antenna for the second cell, is greater than 180 degrees; and, if so, extending the second cell beyond the sector limit line.

25

50. An apparatus according to claim 49, wherein the effective cell-area module comprises means for extending the second cell by a rectangular extension beyond the sector limit line.

30 51. An apparatus according to claim 49, wherein the effective cell-area module comprises means for extending the second cell by rectangular extensions beyond two sector limit lines.

52. An apparatus according to claim 51, wherein the effective cell-area module comprises means for extending the second cell by a triangular extension connecting two rectangular extensions.

5

53. An apparatus according to claim 35 or 37, wherein the penumbra area module comprises means for:

determining the location of the line of equal intensity; and
determining a rectangular strip around the line of equal intensity.

10

54. An apparatus according to claim 53, wherein the means for determining the location of the line of equal intensity comprises means for, when a first antenna for the first cell and a second antenna for the second cell are located at a common location, determining the line of equal intensity as the bisector of an angle formed by a first azimuth for the first cell and a second azimuth for the second cell.

15

55. An apparatus according to claim 53, wherein the means for determining the line of equal intensity comprises means for forming a central perpendicular to a line connecting a first antenna for the first cell and a second antenna for the second cell.

20

56. An apparatus according to claim 53, wherein the rectangular strip is of asymmetrical width about the line of equal intensity.

57. An apparatus according to claim 56, wherein a width W_1 of a first rectangular strip between the line of equal intensity and a first strip limit proximal to a cell into which the cellular device is moving, is longer than a width W_2 of a second rectangular strip between the line of equal intensity and a second strip limit proximal to a cell out of which the cellular device is moving.

25

58. An apparatus according to claim 34, further comprising:
a sampler module of a vehicle traffic information system.

30

59. An apparatus according to claim 58, wherein the sampler module comprises a plurality of sampler sub-modules for sampling vehicle position data from a plurality of different mobile sensor sources.

5

60. An apparatus according to claim 58, further comprising:

a database for storing the handover area, wherein the handover area is pre-determined such that the database is capable of being consulted based on streaming data from the cellular network.

10

61. A method of geographically locating a cellular device by determining the area in which handover from a first cell to a second cell occurs, the method comprising:

modeling at least a portion of a cell reception area of said first cell and said second cell; and

15 defining a handover area comprising overlapping portions of said first and second cell areas.

62. A method according to claim 61, further comprising:

determining whether to extend the cell reception area based on predetermined criteria.

20

63. A method according to claim 62, wherein the predetermined criteria comprise criteria based on a relative orientation of the first cell and the second cell.

64. A method according to claim 62, wherein the predetermined criteria comprise criteria based on relative positions of the first cell and the second cell.

25

65. A method according to claim 61, wherein modeling the at least a portion of the cell reception area of the first cell and the second cell comprises using a pre-defined shape as an initial model of at least a portion of the cell reception area of at least one of the first cell and the second cell.

30

66. A method according to claim 65, wherein the pre-defined shape comprises a sector.

67. A method according to claim 65, wherein the pre-defined shape comprises a ring-sector.

5

68. A method according to claim 61, wherein defining the handover area comprises forming a polygon representing the handover area.

69. A method according to claim 61, wherein defining the handover area comprises forming a penumbra area shape around a line of equal intensity of reception between the first cell and the second cell.

10

70. A method according to claim 69, wherein the penumbra area shape comprises a polygon.

71. A method according to claim 70, wherein the penumbra area shape comprises a rectangle.

15

72. A method of monitoring traffic flow by determining successive locations of a plurality of cellular devices located in a plurality of vehicles, the method comprising:

repeatedly determining the location of at least some of the plurality of cellular devices;

20 and

sampling the locations of the at least some of the cellular devices to determine a present picture of traffic flow;

wherein determining the location of a cellular device of the plurality comprises determining the area in which handover from a first cell to a second cell occurs, the handover determination being based on:

25

modeling at least a portion of a cell reception area of said first cell and said second cell;

and

defining the handover area to comprise overlapping portions of said first and second cell areas.

30

73. A method according to claim 72, further comprising predicting future traffic conditions based on the present picture of traffic flow.

74. A method according to claim 72, wherein the handover determination is made by consulting
5 a database of pre-determined handover areas for cell pairs, using handover data from a cellular network.

75. A method according to claim 72, wherein the handover determination is made online using streaming handover data from a cellular network.

10

76. A method according to claim 74 or 75, wherein the handover data comprises cell-identifier data.

77. A method according to claim 74 or 75, wherein the handover data comprises time advance
15 data.

78. An apparatus for geographically locating a cellular device by determining the area in which handover from a first cell to a second cell occurs, the apparatus comprising:

20 an effective cell-area module for modeling at least a portion of a cell reception area of said first cell and said second cell; and

a handover area module for defining a handover area comprising overlapping portions of said first and second cell areas.

79. An apparatus according to claim 78, wherein the effective cell-area module comprises
25 means for determining whether to extend the cell reception area based on predetermined criteria.

80. An apparatus according to claim 79, wherein the predetermined criteria comprise criteria based on a relative orientation of the first cell and the second cell.

81. An apparatus according to claim 79, wherein the predetermined criteria comprise criteria based on relative positions of the first cell and the second cell.

82. An apparatus according to claim 78, wherein the effective cell-area module comprises

5 means for modeling the at least a portion of the cell reception area of the first cell and the second cell using a pre-defined shape as an initial model of at least a portion of the cell reception area of at least one of the first cell and the second cell.

83. An apparatus according to claim 82, wherein the pre-defined shape comprises a sector.

10

84. An apparatus according to claim 82, wherein the pre-defined shape comprises a ring-sector.

85. An apparatus according to claim 78, wherein the handover area module comprises means for forming a polygon representing the handover area.

15

86. An apparatus according to claim 78, wherein the handover area module comprises means for forming a penumbra area shape around a line of equal intensity of reception between the first cell and the second cell.

20 87. An apparatus according to claim 86, wherein the penumbra area shape comprises a polygon.

88. An apparatus according to claim 87, wherein the penumbra area shape comprises a rectangle.

25 89. An apparatus for monitoring traffic flow by determining successive locations of a plurality of cellular devices located in a plurality of vehicles, the apparatus comprising:

a handover area module for defining a handover area comprising overlapping portions of a modeled cell reception area of at least a portion of each of a first cell and a second cell of a cellular network; and

a sampler module for sampling a set of repeated location determinations of at least some of the plurality of cellular devices, to determine a present picture of traffic flow, wherein each such location determination is based at least in part on the handover area defined by the handover area module for a given cellular device moving between a given first cell and second
5 cell of the cellular network.

90. An apparatus according to claim 89, further comprising:

a predictor module for predicting future traffic conditions based on the present picture of traffic flow.

10

91. An apparatus according to claim 89, further comprising:

a handover area database comprising pre-determined handover areas for cell pairs.

92. An apparatus according to claim 91, wherein the handover area module is capable of

15 consulting the handover area database using streaming handover data from the cellular network.

93. An apparatus according to claim 89, wherein the handover area module is capable of determining the handover area online based on streaming handover data from the cellular network.

20

94. An apparatus according to claim 92 or 93, wherein the handover data comprises cell identifier data.

95. An apparatus according to claim 92 or 93, wherein the handover data comprises time
25 advance data.

96. A method for geographically locating a cellular device, the method comprising:

using an algorithm to determine a handover area within which a cellular device is likely to be located when a control function of the network performs a handover involving addition of a
30 cell to an active set of cells,

wherein the determination of the handover area comprises modeling based on a topological relationship between a plurality of cells in the active set.

97. A method according to claim 96, further comprising:

5 determining a penumbra area around a line of equal intensity of reception among the plurality of cells.

98. A method according to claim 96, wherein the cellular network comprises an antenna for each cell, and wherein the topological relationship is determined from amongst a set of
10 topological cases taking into account the locations and or orientation of each said antennae.

99. A method according to claim 96, further comprising:

 determining a first potential handover area by intersecting the effective cell-area of the first cell with the penumbra area;

15 determining one or more further potential handover areas by intersecting the effective cell-area of the a further cell with a further penumbra area; and

 determining the modeled handover area by forming the union of the first cell potential handover area and the or each further potential handover areas.

20 100. A method according to claim 96, further comprising:

 determining the handover area of the cellular device by intersecting a plurality of effective cell-areas of cells in the active set.

101. A method according to claim 96, wherein determining the effective cell-area comprises
25 using cell identifier data.

102. A method according to claim 96, wherein determining the effective cell-area comprises using time advance data.

103. A method according to claim 96, wherein determining the effective cell-area comprises determining an effective radius the or each cell on the plurality of cells making up the active set.

5 104. A method according to claim 103, wherein the effective radius is determined as a radius of a sector-shaped cell.

105. A method according to claim 103, wherein, the effective radius is determined as the product of a distance between the first antenna and the second antenna and a constant factor based on the topological relationship between cells.

10

106. A method according claim 96. wherein the handover area is determined based on a plurality of effective cell areas and one or more of said effective cell areas is modeled as extended by at least one rectangular extensions.

15 107. A method according to claim 96, wherein the handover area is determined based on a penumbra area, and determining the penumbra area comprises:

determining the location of the line of equal intensity; and

determining a at least one portion around the line of equal intensity.

20 108. A method according to claim 107, wherein the portion is asymmetrical about the line of equal intensity.

109. A method according to claim 96, further comprising:

generating vehicle traffic data based at least in part on a handover area determination.

25

110. A method according to claim 109, further comprising:

sampling data received from the cellular network to determine the handover area.

111. A method according to claim 109, further comprising:

sampling vehicle position data from a plurality of different mobile sensor sources to generate the vehicle traffic data.

112. A method according to claim 109, further comprising:

5 storing a pre-determined handover area for a plurality of cells in a database; and
accessing the database to determine the handover area responsive to data received from the cellular network relating to a handover between the first cell and the second cell.

113. A method according to claim 109, further comprising:

10 determining the handover area using an online sampler which responds to streaming data received from the cellular network.

114. An apparatus for geographically locating a cellular device, the apparatus comprising:

15 an effective cell-area module for determining an effective cell-area for each of a plurality of cells in an active set of cells defined in relation to the mobile device;

a handover area module for determining a handover area within which the cellular device is likely to be located when a control function of the network performs a handover involving addition of a cell to the active set of cells,

20 wherein the determination of the handover area and the effective cell-area for each of the plurality of cells is made based on a topological relationship between said plurality of cells.

115. An apparatus according to claim 114, further comprising:

a penumbra area module for determining a penumbra area around a line of equal intensity of reception between the plurality of cells.

25

116. An apparatus according to claim 114, wherein the cellular network comprises an antenna for each cell, and wherein the topological relationship is determined from amongst a set of predetermined topological cases. 34. An apparatus according to claim 33, wherein the penumbra area module comprises means for, when the topological relationship is determined to be one of

the first, second, or third topological cases, determining a penumbra area around a line of equal intensity of reception between the first cell and the second cell.

117. An apparatus according to claim 114, wherein the handover area module comprises means
5 for:

determining a first potential cell handover area by intersecting the effective cell-area of a first cell of the plurality of cells with the penumbra area;

determining at least one further potential cell handover area by intersecting the effective cell-area of the further cell with the penumbra area; and

10 determining the handover area by forming the union of the potential handover areas.

118. An apparatus according to claim 114, wherein the handover area module comprises means for determining the handover area by intersecting the effective cell-area of a first cell with the effective cell-area of a further cell.

15 119. An apparatus according to claim 114, wherein the effective cell-area module comprises means for using cell identifier data.

20 120. An apparatus according to claim 114, wherein the effective cell-area module comprises means for using time advance data.

121. An apparatus according to claim 114, wherein the effective cell-area module comprises means for determining an effective radius of a first cell and a further cell.

25 122. An apparatus according to claim 114, wherein the effective cell-area module comprises means for determining the effective radius as a radius of a sector-shaped cell.

123. An apparatus according to claim 122, wherein the effective cell-area module comprises means for determining the effective radius as the product of a distance between a at least a first

antenna of a first cell and a further antenna of a further cell and a constant factor based on the topological relationship between at least the first cell and the further cell.

124. An apparatus according to claim 114, wherein the effective cell-area module comprises
5 means for determining an extension cell.

125. An apparatus according to claim 115, wherein the penumbra area module comprises means for:

10 determining the location of the line of equal intensity; and
determining a portion around the line of equal intensity which is to form part of the penumbra area.

126. An apparatus according to claim 125, wherein the portion is asymmetrical about the line of equal intensity.

15

127. An apparatus according to claim 114, further comprising:
a sampler module of a vehicle traffic information system.

128. An apparatus according to claim 114, further comprising:

20 a database for storing handover areas, wherein the handover area is pre-determined such
that the database is capable of being consulted based on streaming data from the cellular
network.

129. A method of geographically locating a cellular device by determining the area in which
25 handover from a first cell or groups of cells to a further cell occurs, the method comprising:
modeling at least a portion of a cell reception area of said first cell or groups of cells and
said further cell; and
defining a handover area comprising overlapping portions of said first cell or groups of
cells and said further cell.

30

130. A method according to claim 129, further comprising:

determining whether to extend the cell reception area of one or more of said cells based on predetermined criteria.

5 131. A method according to claim 130, wherein the predetermined criteria comprise criteria based on a relative orientations of the first cell or groups of cells and the further cell.

132. A method according to claim 130, wherein the predetermined criteria comprise criteria based on relative positions of the first cell or group of cells and the further cell.

10

133. A method according to claim 129, wherein modeling the cell reception area of the first cell or groups of cells and the further cell comprises using a pre-defined shape as an initial model of at least a portion of the cell reception area of at least one of the first cell or groups of cells and the second cell.

15

134. A method according to claim 133, wherein the pre-defined shape comprises a sector.

135. A method according to claim 133, wherein the pre-defined shape comprises a ring-sector.

20 136. A method according to claim 129, wherein defining the handover area comprises forming a polygon representing the handover area..

137. A method according to claim 129, wherein defining the handover area comprises forming a penumbra area shape around a line of equal intensity of reception between the first cell and the
25 second cell.

138. A method according to claim 137, wherein the penumbra area shape comprises a polygon.

139. A method of monitoring traffic flow by determining successive locations of a plurality of
30 cellular devices located in a plurality of vehicles, the method comprising:

repeatedly determining the location of at least some of the plurality of cellular devices;
and

sampling the locations of the at least some of the cellular devices to determine a picture
of traffic flow;

- 5 wherein determining the location of a cellular device of the plurality comprises
determining the area in which handover occurs, the handover determination being based on:
 modeling at least a portion of a cell reception area of a first cell or group of cells and a
further cell; and
 defining the handover area to comprise overlapping portions of said first cell area or
10 groups of cell areas and said further cell area.

140. A method according to claim 139, further comprising predicting future traffic conditions
based on the picture of traffic flow.

- 15 141. A method according to claim 139, wherein the handover determination is made by
consulting a database of pre-determined handover areas for cell pairs and cell sets, using
handover data from a cellular network.

142. A method according to claim 139, wherein the handover determination is made using
20 streaming handover data from a cellular network.

143. A method according to claim 141 or 142, wherein the handover data comprises cell
identifier data.

- 25 144. A method according to claim 141 or 142, wherein the handover data comprises time
advance data.

145. An apparatus for geographically locating a cellular device by determining the area in which
handover from a first cell or group of cell to a further cell occurs, the apparatus comprising:

an effective cell-area module for modeling at least a portion of a cell reception area of said first cell or groups of cells and said further cell; and

a handover area module for defining a handover area comprising overlapping portions of the area of said first cell or group of cells and the further cell area.

5

146. An apparatus according to claim 145, wherein the effective cell-area module comprises means for determining whether to extend the cell reception area based on predetermined criteria.

147. An apparatus according to claim 146, wherein the predetermined criteria comprise criteria
10 based on a relative orientation of the first cell or group of cells and the further cell.

148. An apparatus according to claim 146, wherein the predetermined criteria comprise criteria based on relative positions of the first cell or group of cells and the second cell.

15 149. An apparatus according to claim 145, wherein the effective cell-area module comprises means for modeling the at least a portion of the cell reception area of the first cell or groups of cells and the second cell using a pre-defined shape as an initial model of at least a portion of the cell reception area of at least one of the first cell or groups of cells and the second cell.

20 150. An apparatus according to claim 149, wherein the pre-defined shape comprises a sector.

151. An apparatus according to claim 149, wherein the pre-defined shape comprises a ring-sector.

25 152. An apparatus according to claim 145, wherein the handover area module comprises means for forming a polygon representing the handover area.

153. An apparatus according to claim 145, wherein the handover area module comprises means for forming a penumbra area shape around a line of equal intensity of reception between the first
30 cell or groups of cells and the further cell.

154. An apparatus according to claim 153, wherein the penumbra area shape comprises a polygon.

5 155. An apparatus for monitoring traffic flow by determining successive locations of a plurality of cellular devices located in a plurality of vehicles, the apparatus comprising:

a handover area module for defining a handover area comprising overlapping portions of a modeled cell reception area of at least a portion of each of a first cell or group of cells and a further cell of a cellular network; and

10 a sampler module for sampling a set of repeated location determinations of at least some of the plurality of cellular devices, to determine a present picture of traffic flow, wherein each such location determination is based at least in part on the handover area defined by the handover area module for a given cellular device moving between a given first cell or group of cells a and further cell of the cellular network.

15

156. An apparatus according to claim 155, further comprising:

a predictor module for predicting future traffic conditions based on the present picture of traffic flow.

20 157. An apparatus according to claim 155, further comprising:

a handover area database comprising pre-determined handover areas for cell pairs or cell sets.

25 158. An apparatus according to claim 157, wherein the handover area module is capable of consulting the handover area database using streaming handover data from the cellular network.

159. An apparatus according to claim 155, wherein the handover area module is capable of determining the handover area online based on streaming handover data from the cellular network.

30

160. An apparatus according to claim 158 or 159, wherein the handover data comprises cell identifier data.

5 161. An apparatus according to claim 158 or 159, wherein the handover data comprises time advance data.

162. According to a an aspect of the present invention, there is provided a method for geographically locating a cellular device, the method comprising:

10 using an algorithm to determine an area within which a cellular device is likely to be located when a control function records an event which can be connected to concurrent control of more than one cell, wherein the determination of the area comprises modeling based on a topological relationship between a plurality of cells.
