Description

TECHNICAL FIELD

[0001] The present invention relates to a benzodiazepine compound and a pharmaceutical composition.

BACKGROUND ART

[0002] Atrial fibrillation (hereinafter referred to as "AF") is the most frequently observed type of arrhythmia in clinical examinations. Although not a lethal arrhythmia, AF causes cardiogenic cerebral embolism, and is therefore recognized as an arrhythmia that greatly affects vital prognoses and QOL. It is known that the onset of AF increases with age, and that repeated AF strokes lead to chronic (serious) AF (The Journal of American Medical Association, 285, 2370-2375 (2001) and Circulation, 114, 119-123 (2006)).

[0003] To prevent chronic AF, which causes difficulty in restoring sinus rhythm and increases the risk of cardiogenic cerebral embolism, early defibrillation and subsequent prevention of recurrence (maintenance of the sinus rhythm) are required. Antiarrhythmic drugs (classes I and III) are most commonly used as pharmacotherapy, but these drugs achieve insufficient therapeutic effects, while causing serious side effects such as a proarrhythmic effect (Am. J. Cardiol., 72, B44-B49 (1993)).

[0004] The onset of AF is triggered by atrial premature contraction with underlining causes such as intra-atrial conduction delay, shortening and heterogeneity of the atrial refractory period (Nature Reviews DRUG DISCOVERY 4, 899-910 (2005)). It is known that the prolongation of refractory period of atrial muscle can terminate AF (defibrillation) or prevent the occurence of AF. The action potential duration of the mammalian cardiac muscle is predominantly determined by voltage-dependent K^+ channels. Inhibition of the K^+ channel prolongs myocardial action potential duration, which results in prolongation of the refractory period (Nature Reviews DRUG DISCOVERY 5, 1034-49 (2006)). The action mechanism of class III antiarrhythmic drugs (e.g., Dofetilide) is to inhibit rapid delayed rectifier K^+ current (I_{Kr}), K^+ current encoded by HERG. However, since I_{Kr} is present in both the atria and ventricles, such drugs might cause ventricular arrhythmias, such as torsades de pointes (Trends Pharmacol. Sci., 22, 240-246 (2001)).

[0005] Ultra-rapid delayed rectifier K^+ current (I_{Kur}), K^+ current encoded by Kv1.5, has been identified as K^+ channel that is specifically expressed only in human atria (Circ. Res., 73, 1061-1076 (1993), J. Physiol., 491, 31-50 (1996) and Circ. Res., 80, 572-579 (1997)). Muscarine potassium current (I_{KACh}) encoded by two genes called GIRK1 and GIRK4 is known as a K^+ channel specifically expressed in human atria (Nature 374, 135-141 (1995)). Accordingly, a pharmacologically acceptable substance that selectively blocks the I_{Kur} current (the Kv1. 5 channel) or the I_{KACh} current (GIRK1/4 channel) can act selectively on the atrial muscle and is considered effective to exclude the proarrhythmic effect caused by prolonged action potential duration of the ventricular muscle.

DISCLOSURE OF THE INVENTION

[0006] The present inventors conducted extensive research to develop a compound that blocks the I_{Kur} current (Kv1.5 channel) and/or the I_{KACh} current (GIRK1/4 channel) potently and more selectively than other K^+ channels. As a result, the inventors found that a novel benzodiazepine compound represented by General Formula (1) below could be the desired compound. The present invention has been accomplished based on the above findings.

The reaction of the obtained mixed acid anhydride with Amine (11) is usually carried out at about -20 to about 150°C, and preferably at about 10 to about 50°C, usually for about 5 minutes to about 30 hours, and preferably for about 5 minutes to about 25 hours. Generally, the mixed acid anhydride method is performed in a solvent. Solvents used for conventional mixed acid anhydride methods are usable. Examples of usable solvents include chloroform, dichloromethane, dichloroethane, carbon tetrachloride and other halogenated hydrocarbons; benzene, toluene, xylene and other aromatic hydrocarbons; diethyl ether, diisopropyl ether, tetrahydrofuran, dimethoxyethane and other ethers; methyl acetate, ethyl acetate, isopropyl acetate and other esters; N,N-dimethylformamide, dimethylsulfoxide, hexamethylphosphoric triamide and other aprotic polar solvents; mixtures thereof; etc. Examples of alkyl halocarboxylates usable in the mixed acid anhydride method include methyl chloroformate, methyl bromoformate, ethyl chloroformate, ethyl bromoformate, isobutyl chloroformate, etc. In this method, Carboxylic Acid (12), an alkyl halocarboxylate, and Amine (11) are preferably used in equimolear amounts, but each of the alkyl halocarboxylate and Carboxylic Acid (12) can also be used in an amount of about 1 to about 1.5 moles per mole of Amine (11).

[0066] Method (C), in which a condensation reaction is carried out in the presence of an activating agent, can be performed in a suitable solvent in the presence or absence of a basic compound. Solvents and basic compounds usable in this method include those mentioned hereinafter as solvents and basic compounds usable in the method in which a carboxylic acid halide is reacted with Amine (11) mentioned above as one of the other methods (D). A suitable amount of activating agent is at least 1 mole, and preferably 1 to 5 moles per mole of Amine (11). When using WSC as an activating agent, addition of 1-hydroxybenzotriazol to the reaction system enables the reaction to proceed advantageously. The reaction is usually performed at about -20 to about 180°C, and preferably at about 0 to about 150°C, and is usually completed in about 5 minutes to about 90 hours.

[0067] When the method in which a carboxylic acid halide is reacted with Amine (11), mentioned above as one of the other methods (D), is employed, the reaction is performed in the presence of a basic compound in a suitable solvent. Usable basic compounds include a wide variety of known basic compounds, such as those for use in the Schotten-Baumann reaction described above. Usable solvents include, in addition to those usable in the mixed acid anhydride method, methanol, ethanol, isopropanol, propanol, butanol, 3-methoxy-1-butanol, ethylcellosolve, methylcellosolve and other alcohols; acetonitrile; pyridine; acetone; water; etc. The ratio of the carboxylic acid halide to Amine (11) is not limited and can be suitably selected from a wide range. It is usually suitable to use, for example, at least about 1 mole, and preferably about 1 to about 5 moles of the carboxylic acid halide per mole of Amine (11). The reaction is usually performed at about -20 to about 180°C, and preferably at about 0 to about 150°C, and usually completed in about 5 minutes to about 30 hours.

[0068] The amide bond formation reaction shown in Reaction Formula 10 can also be performed by reacting Carboxylic Acid (12) with Amine (11) in the presence of a phosphorus compound serving as a condensing agent, such as triphe-

nylphosphine, diphenylphosphinyl chloride, phenyl-N-phenylphosphoramide chloridate, diethyl chlorophosphate, diethyl cyanophosphate, diphenylphosphoric azide, bis(2-oxo-3-oxazolidinyl)phosphinic chloride or the like.

It is suitable to use each of the condensing agent and Carboxylic Acid (12) in amounts of at least about 1 mole, and preferably about 1 to about 2 moles per mole of Amine (11).

[0070] The reaction converting the compound of Formula (13) to the compound of Formula (14) can be carried out by, for example, (1) reducing the compound of Formula (13) in a suitable solvent using a catalytic hydrogenation reducing agent, or (2) reducing the compound of Formula (13) in a suitable inert solvent using as a reducing agent a mixture of an acid with a metal or metal salt, a mixture of a metal or metal salt with an alkali metal hydroxide, sulfide, or ammonium salt, or the like.

The reaction temperature is usually about -20 to about 150°C, and preferably about 0 to about 100°C. The hydrogen pressure is usually about 1 to 10 atm. The reaction is usually completed in about 0.5 to about 100 hours. An acid such as hydrochloric acid may be introduced into the reaction system of the reaction.

[0072] When using Method (2) above, a mixture of iron, zinc, tin, or tin (II) chloride, with a mineral acid such as hydrochloric acid, or sulfuric acid; or a mixture of iron, iron (II) sulfate, zinc, or tin, with an alkali metal hydroxide such as sodium hydroxide, a sulfide such as ammonium sulfide, aqueous ammonia solution, or an ammonium salt such as ammonium chloride, or the like can be used as a reducing agent. [0117] The following is an explanation of pharmaceutical preparations comprising the compound of the present inven-

tion as an active ingredient.

[0118] Such pharmaceutical preparations are obtained by formulating the compound of the present invention into usual pharmaceutical preparations, using usually employed diluents or excipients such as fillers, extenders, binders, wetting agents, disintegrants, surfactants, lubricants, etc.

[0119] The form of such pharmaceutical preparations can be selected from various forms according to the purpose of therapy. Typical examples include tablets, pills, powders, solutions, suspensions, emulsions, granules, capsules, suppositories, injections (solutions, suspensions, etc.) and the like.

[0120] To form tablets, any of various known carriers can be used, including, for example, lactose, white sugar, sodium chloride, glucose, urea, starch, calcium carbonate, kaolin, crystalline cellulose and other excipients; water, ethanol, propanol, simple syrup, glucose solutions, starch solutions, gelatin solutions, carboxymethylcellulose, shellac, methylcellulose, potassium phosphate, polyvinylpyrrolidone and other binders; dry starch, sodium alginate, agar powder, laminaran powder, sodium hydrogencarbonate, calcium carbonate, fatty acid esters of polyoxyethylenesorbitan, sodium laurylsulfate, stearic acid monoglyceride, starch, lactose and other disintegrants; white sugar, stearin, cacao butter, hydrogenated oils and other disintegration inhibitors; quaternary ammonium base, sodium lauryl sulfate and other absorption promoters; glycerin, starch and other wetting agents; starch, lactose, kaolin, bentonite, colloidal silicic acid and other adsorbents; purified talc, stearates, boric acid powder, polyethylene glycol and other lubricants; etc.

[0121] Such tablets may be coated with usual coating materials as required, to prepare, for example, sugar-coated tablets, gelatin-coated tablets, enteric-coated tablets, film-coated tablets, double- or multi-layered tablets, etc.

[0122] To form pills, any of various known carriers can be used, including, for example, glucose, lactose, starch, cacao butter, hydrogenated vegetable oils, kaolin, talc and other excipients; gum arabic powder, tragacanth powder, gelatin, ethanol and other binders; laminaran, agar and other disintegrants; etc.

[0123] To form suppositories, any of various known carriers can be used, including, for example, polyethylene glycol, cacao butter, higher alcohols, esters of higher alcohols, gelatin, semisynthetic glycerides, etc.

[0124] To form an injection, a solution, emulsion or suspension is sterilized and preferably made isotonic with blood. Any of various known widely used diluents can be employed to prepare the solution, emulsion or suspension. Examples of such diluents include water, ethanol, propylene glycol, ethoxylated isostearyl alcohol, polyoxylated isostearyl alcohol, fatty acid esters of polyoxyethylene sorbitan, etc. In this case, the pharmaceutical preparation may contain sodium chloride, glucose or glycerin in an amount sufficient to prepare an isotonic solution, and may contain usual solubilizers, buffers, analgesic agents, etc., and further, if necessary, coloring agents, preservatives, flavors, sweetening agents, etc., and/or other medicines.

[0125] The proportion of the compound of the present invention in the pharmaceutical preparation is not limited and can be suitably selected from a wide range. It is usually preferable that the pharmaceutical preparation contain the compound of the present invention in a proportion of 1 to 70 wt.%.

[0126] The route of administration of the pharmaceutical preparation according to the present invention is not limited, and the preparation can be administered by a route suitable for the form of the preparation, the patient's age and sex, the conditions of the disease, and other conditions.

For example, tablets, pills, solutions, suspensions, emulsions, granules and capsules are administered orally.

Injections are intravenously administered singly or as mixed with usual injection transfusions such as glucose solutions, amino acid solutions or the like, or singly administered intramuscularly, intracutaneously, subcutaneously or intraperitoneally, as required. Suppositories are administered intrarectally.

[0127] The dosage of the pharmaceutical preparation is suitably selected according to the method of use, the patient's age and sex, the severity of the disease, and other conditions, and is usually about 0.001 to about 100 mg/kg body weight/day, and preferably 0.001 to 50 mg/kg body weight/day, in single or divided doses.

[0128] Since the dosage varies depending on various conditions, a dosage smaller than the above range may be sufficient, or a dosage larger than the above range may be required.

[0129] When administered to the human body as a pharmaceutical, the compound of the present invention may be used concurrently with, or before or after, antithrombotics such as blood clotting inhibitors and antiplatelet agents (e.g., warfarin, aspirin, etc.). Further, the present compound may be used concurrently with, or before or after, drugs for treating chronic diseases, such as antihypertensive drugs (ACE inhibitors, beta blockers, angiotensin II receptor antagonists), heart failure drugs (cardiotonic agents, diuretics), and diabetes treatment agents.

[0130] The compound of the present invention has potent blocking effects on human Kv1.5 and/or GIRK1/4 channels, and weak blocking effects on HERG channels. Thus, the compound of the invention has characteristics as an atrial-selective K^+ channel-blocking agent.

[0131] Therefore, the compound of the invention can be used as a pharmacologically active substance that is safer and provides a more potent effect on the prolongation of the atrial refractory period than conventional antiarrhythmic agents. The compound of the invention is preferably used as a therapeutic agent for arrhythmia such as atrial fibrillation, atrial flutter, and atrial tachycardia (elimination of arrhythmia and/or prevention of the occurrence of arrhythmia). The compound of the invention is particularly preferably used as a therapeutic agent for atrial fibrillation (defibrillation and

maintenance of sinus rhythm). The compound of the invention can also be used as a prophylactic agent for thromboembolism such as cerebral infarction and as a therapeutic agent for heart failure.

[0132] The compound having potent blocking effects on both human Kv1.5 and human GIRK1/4 channels has more potent atrial refractory period prolongation effects and is highly safe, compared to compounds inhibiting either one of the channels. Furthermore, this compound has greater therapeutic effects on atrial fibrillation (defibrillation and maintenance of sinus rhythm) than compounds inhibiting either one of the channels. Therefore, the compound having potent blocking effects on both the human Kv1.5 and human GIRK1/4 channels is particularly useful as a therapeutic agent for arrhythmia such as atrial fibrillation, atrial flutter, and atrial tachycardia (termination of arrhythmia and/or prevention of the occurrence of arrhythmia). This compound is particularly useful as a therapeutic agent for atrial fibrillation (defibrillation and maintenance of sinus rhythm).

[0303] A 2N-Sodium carbonate aqueous solution (0.3 ml) and tetrakis(triphenylphosphine)palladium(0) (37.2 mg, 0.03 mmol) were added to a dimethoxyethane solution (2 ml) of 7-(3-{[2-(2-bromo -4-oxo-4H-furo[3,2-c]pyridin-5-yl)ethyl]pyridin-4-ylmethylamino} propoxy)-1-ethyl-3,3,5-trimethyl-1,5-dihydrobenzo[b] [1,4]diazepin e-2,4-dione (0.20 g, 0.31 mmol) and furan-3-boronic acid (39.2 mg, 0.035 mmol), and stirred under argon atmosphere at 80°C for 6.5 hours. The reaction mixture was cooled to room temperature, and purified by silica gel column chromatography (ethyl acetate:methanol=100:0→93:7). The purified product was concentrated under reduced pressure and the resultant residue was dissolved in ethyl acetate (10 ml). A 4N-HCl ethyl acetate solution (0.5 ml) was added to the solution, and concentrated to dryness under reduced pressure to thereby obtain 0.10 g (yield:51%) of 1-ethyl-7-(3-{[2-(2-furan-3-yl-4-oxo-4H-furo [3,2-c]pyridin-5-yl) ethyl]pyridin-4-ylmethylamino}propoxy)-3,3,5-trimethyl-1,5-dihydrobenzo[b][1,4]diazepine-2,4-dione dihydrochloride as a pale yellow amorphous solid.

[0468] Benzoyl chloride (0.091 ml, 0.78 mmol) was added to an acetonitrile solution (3 ml) of 1-ethyl-3,3,5-trimethyl-7-[3-(2-pyridin-3-ylethylamino)propoxy] -1,5-dihydrobenzo[b] [1,4]diazepine-2,4-dione (0.39 g, 0.71 mmol) and triethylamine (0.12 ml, 0.86 mmol) while cooling in an ice-bath, and the mixture was stirred at room temperature overnight. Water was added to the reaction mixture, and extraction with ethyl acetate was conducted. The organic layer was dried over anhydrous sodium sulfate and concentrated under reduced pressure. The residue thus obtained was purified by medium pressure liquid chromatography (silica gel, ethyl acetate: isopropyl alcohol=100: 0→92:8). The purified product was concentrated under reduced pressure and the resultant residue was dissolved in ethyl acetate (10 ml). A 1N-HCl ethanol solution (0.65 ml) was added to the solution, and concentrated under reduced pressure. The residue was recrystallized from ethyl acetate to thereby obtain 0.28 g (yield:54%) of N-[3-(1-ethyl-3,3,5-trimethyl-2,4-dioxo-2,3,4,5-tetrahydro-1H-benzo [b] [1,4] diazepin-7-yloxy) propyl] -N-(2-pyridin-3-ylethyl)benzamide hydrochloride as a white powder. Pharmacological Test 1

(1) Production of human Kv1.5-expressing CHO-K1 cell lines

[0543] CHO-K1 cell lines stably expressing human Kv1.5 channels were prepared in the following manner.

[0544] Full-length human Kv1.5 cDNA was cloned from a human, heart cDNA library (produced by Stratagene). The obtained human Kv1.5 sequence corresponds to the sequence described in FASEB J. 5, 331-337 (1991).

[0545] The obtained human Kv1.5 cDNA was inserted into a plasmid encoding a CMV promoter and a G418 resistance marker to produce a Kv1.5 expression vector. The human Kv1.5 expression vector was transfected into CHO-K1 cells by the lipofectamine method. After culturing the cells in an F-12 medium (produced by Invitrogen Corp.) containing 10% FBS (produced by Invitrogen Corp.) for 3 or 4 days, the medium was replaced with a FBS-containing F-12 medium that included 1, 000 μg/ml of G418 (produced by Invitrogen Corp.), and single colonies were isolated. The amount of Kv1.5 channel expression in the single colonies was quantified at the mRNA level by RT-PCR and then quantified at the protein level by western blotting. Finally, the expressed current was analyzed by patch clamp method. Cell lines expressing a current of 200 pA or more per cell were selected as channel-expressing cell lines for activity measurement by patch clamp method.

(2) Production of CHO cell line expressing human GIRK1/4

[0546] CHO cell lines stably expressing human GIRK1/4 channels were prepared in the following manner.

[0547] Full-length human GIRK1 cDNA was cloned from HuH cell- and HeLa cell-derived cDNA libraries. Full-length GIRK4 cDNA was amplified from a human heart cDNA library (produced by Clontech Laboratories, Inc.) by PCR using synthetic primers shown in Table 1, and cloned into the Eco-RI restriction enzyme site of pCR-Blunt (produced by Invitrogen Corporation) or into the HincII site of pUC118 (produced by Takara Bio, Inc.).

[0548] The obtained human GIRK1 and GIRK4 cDNA.sequences correspond to known sequences (NCBI database: GIRK1 (NM_002239) and GIRK4 (NM_000890) respectively). The obtained GIRK1 and GIRK4 cDNA sequences were cloned into the Eco-RI restriction enzyme site of pCR-Blunt (available from Invitrogen Corporation) or into the HincII site of pUC118 (available from Takara Bio, Inc.). A GIRK4 expression vector was constructed by insertion into the BamHI-XhoI site of pcDNA5/FRT. A GIRK1 expression vector was constructed by insertion into the KpnI-XhoI site of pcDNA3. 1 (+) or pCAG_neo. FLP-IN-CHO cells (produced by Invitrogen Corporation) were transfected with human GIRK1 and GIRK4 expression vectors by using Lipofectamine 2000 (produced by Invitrogen Corporation) according to the protocol enclosed with the reagent or using an electronic induction method ("Nucleofector Kit-T", produced by Amaxa). First, the cells transfected with the GIRK4 expression vector were cultured in a 10% serum-containing F12 medium (produced by Sigma) supplemented with 600 μg/ml of hygromycin in an incubator with 5% carbon dioxide at 37°C. Then the cells expressing GIRK4 were transfected with the GIRK1, expression vector and were cultured in 10% serum-containing F12 medium supplemented with 350 μg/ml of G418 and 600 μg/ml of hygromycin in an incubator with 5% carbon dioxide at 37°C to select GIRK1/4 expressing cell lines. Cell populations whose growth was observed after about 2 weeks were isolated using cloning rings, and the obtained single colonies were proliferated. RNA was extracted from single colonies, and single-stranded cDNA was synthesized by a cDNA synthesis kit (produced by Invitrogen Corporation), and the amount of expression was quantified at the mRNA level by real-time PCR (Applied Biosystems, Ltd.). Finally, the expressed current was analyzed by patch clamp method described below. The cell lines expressing a current of 500 pA or more per cell were selected as channel-expressing cell lines for activity measurement by patch clamping method.

(3) Measurement of ion channel current by patch clamp method (human Kv1.5-expressing CHO-K1 cell line)

[0549] An experiment was carried out using a patch clamp setup at room temperature (20 to 26°C). A perfusion chamber having a diameter of 20 mm (flow rate: about 5 ml/min) was mounted on the stage of a phase-contrast inverted microscope (produced by Nikon Corporation) placed on a vibration isolated table. A poly-L-lysine (produced by Sigma)-coated coverslip (diameter: 15 mm, produced by Matsunami Glass Ind., Ltd.) on which human Kv1.5-expressing cells were cultured was placed in the perfusion chamber.

[0550] Depolarizing stimulation pulses were applied and ionic current was recorded by using a patch clamp amplifier (EPC-7 or EPC-7 PLUS, produced by HEKA) and a personal computer (manufactured by IBM Corp.) in which software for data acquisition and analysis of ion channel current (PULSE 8.77, produced by HEKA) was installed. The current was measured in the whole-cell configuration of the patch-clamp technique. The tip (resistance: 2 to 4 MΩ) of a borosilicate glass pipette (produced by Sutter Instrument Co.) was gently placed on the cell membrane by using a three-dimensional mechanical micromanipulator (produced by Shoshin EM Corporation). Weak suction resulted in giga seal formation (the pipette resistance increased to more than 1 GΩ). Subsequently, stronger suction was applied to break the cell membrane. The capacitative current derived from the cell membrane was corrected using a patch clamp amplifier. Subsequently, the series resistance (Rs) between the pipette and the interior of the cell was measured and corrected.

[0554] An experiment was carried out using a patch clamp setup at room temperature (20 to 26°C). A perfusion chamber having a diameter of 20 mm (flow rate: about 5 ml/min) was mounted on the stage of a phase-contrast inverted microscope (produced by Nikon Corporation) placed on a vibration isolation table. (5) Measurement of human Kv1.5 current

[0559] While the membrane potential was holded at -80 mV, depolarizing pulses (-80 mV for 0.05 seconds → +40 mV for 0.2 seconds → -40 mV for 0.2 seconds → -80 mV for 0.05 seconds) were applied at a stimulation frequency of 1 Hz to measure Kv1.5 channel current. More specifically, first, while perfusing an extracellular solution containing 0.1% DMSO and holding the membrane potential at -80 mV, depolarizing pulses were applied. The current obtained during the pulse application was recorded as a current in the absence of the test compounds. Subsequently, while perfusing an extracellular solution containing 0.1 μM of a test compound and holding the membrane potential at -80 mV, depolarizing pulses were applied. After the inhibitory effect of the test compound had been stabilized, the current was recorded. The same procedure was repeated using an extracellular solution containing 1 μM of the test compound and then using an extracellular solution containing 10 μM of the test compound. The current obtained using the solution containing the test compound at each concentration was recorded.

[0560] The data was analyzed by using the step end current recorded during the +40 mV depolarizing stimulation. The "step end current" refers to the average current flowing for a period of 195 to 199 milliseconds from the start of the +40 mV depolarizing pulse stimulation.

[0561] Using the step end current in the presence of the test compound and the step end current in the absence of the test compound, the relative current in the solution containing the test compound at each concentration was calculated according to the following formula:

Relative current =
(Step end current in the presence of the test compound) / (Step end current in the absence of the test compound)

(6) Measurement of human GIRK1/4 current

[0562] While the membrane potential was holded at -80 mV, hyperpolarizing pulses (-80 mV for 0.05 seconds → -120 mV for 0.2 seconds → -80 mV for 0.05 seconds) were applied at a stimulation frequency of 1 Hz to measure GIRK1/4 channel current. More specifically, first, while perfusing an extracellular solution containing 0.1% DMSO and maintaining the membrane potential at -80 mV, hyperpolarizing pulses were applied. The current obtained during the pulse application was recorded as the current in the absence of the test compounds. Subsequently, while perfusing an extracellular solution containing 0.1 μM of a test compound and maintaining the membrane potential at -80 mV, hyperpolarizing pulses were applied. After the inhibitory effect of the test compound had been stabilized, the current was recorded. The same procedure was repeated using an extracellular solution containing 1 μM of the test compound and then using an extracellular solution containing 10 μM of the test compound. The current obtained using the solution containing the test compound at each concentration were recorded.

[0563] The data was analyzed by using the step end current recorded during the -120 mV depolarizing stimulation. The "step end current" refers to the average current flowing for a period of 195 to 199 milliseconds from the start of the -120 mV depolarizing pulse stimulation.

[0564] Using the step end current in the presence of the test compound and the step end current in the absence of the test compound, the relative current in the solution containing the test compound at each concentration was calculated according to the following formula:

Relative current =
(Step end current in the presence of the test compound) / (Step end current in the absence of the test compound)

(7) Calculation of inhibitory activity on Kv1.5 channel ionic current and GIRK1/4 channel current

[0565] The concentration for 50% inhibition of Kv1.5 channel current or GIRK1/4 channel current (IC_{50} value) was calculated according to the following nonlinear regression equation:

Relative current = 1/(1+ [Concentration of the compound]/IC_{50})^{nH}
wherein nH is the Hill coefficient.

[0566] Table 78 shows the test results..
